In the *monkey* tribe there are nine bones in the *carpus*, which is one more than in man. According to Tyfon, however, there are but eight in the *ourang-outang*. The *pisiform bone* of these animals is elongated, and appears like a heel when they walk upon all fours, or use the anterior extremities as feet. Certain ossified points of the tendons passing into the hand, have been mistaken for supernumerary bones in the *monkey* kind.

The *flying squirrel* is mentioned by Blumenbach as possessing a very curious sharp-pointed bone on the outer part of the carpus, connected to that part by two small round bones, and inclosed in the lateral expansion of the integuments.

In many *carnivorous* quadrupeds, the *scaphoides* and *lunare* are united into one. The *cat* has at the radial edge of the carpus a little supernumerary bone, similar in figure to the *pisiform* bone of the human subject. The real *os pisiforme* of the *digitigrade* is long, and serves as a sort of heel to the fore-foot. The *os magnum* is very small towards the back of the carpus. Those that have the thumb imperfect have also the *trapezium* much diminished. The *ursus gulo* has this bone also small, and a style-shaped process below the *os scaphoides*.

The *mole* has nine bones in the carpus, and an additional

bone which resembles the blade of a scythe in its figure. It descends on the radial side of the hand, the surface of which it is designed to extend, in order to fit it for shovelling back the earth when this animal burrows.

Amongst the *saligrada*, the *hare* has nine carpal bones. The *beaver*, *marmot*, *squirrel*, and *rat* tribe have the scaphoid and lunar bones formed into one. These animals likewise have, like the *digitigrada*, a supernumerary bone, which is often larger than the pisiform. In the *jerboa* and *marmot*, it bears upon it another supernumerary bone. In the *porcupino* there is an additional carpal bone, attached to the *os unciniforme*, between the *os pisiforme* and the metacarpal bone of the small toe. The *cavy* and *guinea-pig* have one bone for the scaphoid and lunar; and the latter animal has a small supernumerary carpal bone.

The *two-toed ant-eater* has six bones in the carpus. There are seven in the *pangolin*. There are eight found in the *nine-banded armadillo*.

The *three-toed sloth* has but five carpal bones.

The *elephant* has eight bones. The *os pisiforme* is lengthened, and the other bones of a wedge shape.

In the *rhinoceros* the trapezium does not exist, but there are two supernumerary bones; one on the edge of the scaphoides, and the other upon the *os unciniforme*.

In the other *many-hoofed* quadrupeds the trapezium is very small.

In the *cloven* and *solid-footed* quadrupeds the carpal bones are narrow. The first tribe have, in general, four bones in the first row, and two in the second. The *solipeda* have four in the first and three in the second row.

In the *cetacea* the bones of the carpus are flat-shaped, and intimately united to each other by cartilage and ligament. We have found the carpus of the *grampus* to contain a greater proportion of cartilaginous substance than of osseous, the bones appearing like spots of ossification in the centres of masses of cartilage. The surface of the carpus in *cetacea* is smooth on both sides. There are five carpal bones, three in the first row and two in the second.

The *metacarpus* consists of the same number of bones as the fingers, (or, as they are more commonly called, toes, in quadrupeds,) perhaps without exception; it being understood, that the *pollex* is not reckoned amongst the number of fingers, for it is a question amongst anatomists, whether the first joint of the thumb, in the human subject, should be considered as a metacarpal bone, or as a real phalanx. We believe it is the latter, which opinion seems to be supported not only by analogy of structure in mammalia, but in birds.

The *cloven* and *solid-hoofed* quadrupeds have been cited as giving examples of a difference in the number of the metacarpal bones and the *digit*. This difference, however, is more apparent than real. The *cloven-hoofed* have, it is true, but one bone in the metacarpus after a certain age, which is called the *cannon bone* (*gamba* of Vegetius), but this bone is originally composed of two parallel pieces, which are formed into one by a curious process. The two sides of the pieces that are applied to each other are rendered thinner by being absorbed: these are next portions of the sides removed, leaving holes between the cavities of the two pieces; and ultimately the sides in contact disappear, forming a common medullary cavity, and a single bone, which remains grooved at the line of the junction of its original parts.

The *cannon bone* of the *solipeda* is composed of three pieces; the two lateral are slender and styiform, and are called, very appropriately, the *splent* bones. These have been considered analogous to the metacarpal bones of *digit* which do not

MAMMALIA.

exist, but they should rather, perhaps, be viewed as the rudiments of both metacarpal bones and digits. In other cases where there are vestiges of digits, they appear as styli-form bones.

The length of the metacarpal bones depends upon the offices of the anterior extremity. When it is employed solely for progression, as in the true quadrupeds, the metacarpus is very long, but when used as a prehensile member, this part is proportionally short.

Cuvier states, that in the *three-toed sloth* there are three metacarpal bones united into one at their base, and that there is a rudiment of a fourth bone added to them.

The metacarpal bones of *cetacea*, from contributing to the formation of a fin, are much flattened.

The *digits* of the *quadrumanous* mammalia, and all those with claws, are five in number. In the first, the pollex is free in its motions, and capable of being brought opposite to the other fingers, which constitutes one of their most striking resemblances to man.

Even in the *monkey tribe*, however, the thumb is shorter and smaller, in proportion to the other fingers, than the thumb of the human subject; and a particular species of *monkey*, the *simia paniscus*, has it imperfect, and concealed beneath the skin.

The *digitigrada* have the thumb parallel to the rest of the toes: in many it is short, and in the *hyena* it is nearly obliterated, consisting only of one phalanx. In the *cat* genus, there is a peculiar structure of the two last phalanges, by which the claws are thrown upwards in the extended state of the toes. The design of this appears to be, to avoid the blunting of the claws against the ground. The last phalanx but one is three-sided, having an inferior and two lateral surfaces; that on the inside appears in some degree twisted and hollowed out. The phalanx, which is terminated by the claw, is, of course, hooked at the end, but at its base, nearer the root of the claw, in a sort of hood or sheath. The posterior part of the phalanx rises almost vertically, and is only articulated at its most inferior part. Beneath the joint there are two appendices, in which the muscles which bend the phalanx are inserted. These also bring the point of the claw forwards and downwards. The same muscular power which puts the toes into a flex position, thus serves also to urge downwards the points of the claws into the prey of these animals. When the claws are retracted, the last phalanx is received by the lateral depression on the radial side of the second.

The *pollex* is short in the *beaver*, and *jerboa*. It is more diminished in the *squirrel*, *rat*, *porcupine*, *paca*, and *agouti*. It is nearly lost in the *cavy*, *marmot*, *guinea-pig*, &c.

Amongst the *edentata* the thumb is obliterated in the *great* and the *four-toed ant-eaters*.

Both it and the little toe are lost in the *three-toed sloth*. In this animal the three perfect toes are often incorporated at their roots with the metacarpus. When they form a joint with the metacarpal bones, it is such a one as does not permit any lateral motion. The phalanges themselves likewise are articulated with each other by hinge-like surfaces, which only admit of flexion and extension. Another peculiarity of the hand of this animal is, the last phalanx being the longest.

In the *two-toed ant-eater* and *two-toed sloth*, the thumb, fore, and little finger are the different parts.

The *multungulata* have either four or five toes. In the *elephant* there are five perfect, but they are nearly enveloped in the skin of the foot. There are but three perfect in the

rhinoceros. The *hog* has but two perfect and two imperfect.

The *tapir* and *hippopotamus* have four perfect, and the rudiment of a thumb.

The *clown-hoofed* have two perfect, and in some two imperfect toes.

The *solid-hoofed* have one perfect and two imperfect.

By imperfect toes, or digits, are meant those little horny excrescences which do not reach the ground, but are placed at the back, and are sometimes covered with nails or hoofs, and contain under the skin the proper bones of a toe.

The most remarkable deviations from the usual structure are found in the flying and aquatic mammalia. The very extensive wings of the *bat* are supported upon the elongated phalanges of the four fingers, the thumb being short, and armed with a hooked nail at the extremity.

In the *seal* and *lamantin* the fingers are elongated a good deal, and spread out, that the hand may the better perform the office of an oar. In the *cetacea* the digits are rather elongated, and are much flattened. They are conjoined with the metacarpus and each other by cartilaginous surfaces, that do not permit any motion beyond the gentle waying one of the fin, in which they are concealed. The digits are close together at their bases, but spread a little asunder towards their extremities; but they are all bound together by means of the ligamentous substance which supports and strengthens the different parts of the fin.

The *ossa innominata* are more elongated and narrower in mammalia generally than in man. They do not in any instance form a basin-shaped cavity, like the human pelvis. In many quadrupeds, the cavity of the *ossa innominata* wants the distinction of the large and small pelvis, and is placed in the direction of the spine; and in some this cavity looks obliquely upwards, that is to say, backwards, if we were speaking of the human subject.

The *monkey* and *bear* most nearly resemble man with respect to the form of the pelvis, but even they have the *os ilii* elongated, and the cavity of the pelvis much narrower than in man, and not opening so much forwards. Those *monkeys* that have the callosities on the buttocks, have the *tuberosities of the ischium* very large, and spread out.

In the *vampire bat*, the tuberosities of the ischium and the extremity of the sacrum are consolidated together by ankylosis, of which there is no other example in this whole class. The pelvic bones are less elongated in the *bats*, generally, than in quadrupeds.

The *digitigrada* have the abdominal surfaces of the ileum turned towards the spine, and so much narrowed, that the dorsum of the bone is not larger than the neck. The concavity is also upon the external surface. The crista of the ileum is so short, that it bears no resemblance to that part in the human subject. The form of the pelvic bones is nearly similar in the *plantigrade* and *saligrade* quadrupeds, with some exceptions. In the *mole*, the *ossa innominata* are nearly cylindrical; they are long, and lie almost close to the spine: the cavity of the pelvis is so very narrow, that it can only receive the rectum, the organs of generation and bladder being placed externally to it. The *beaver* and *kangaroo* have the *os pubis* not united by cartilage, but are ankylosed together.

In the *opossum* tribe and the *kangaroo*, the brim of the pelvis has but little extent, and there are two additional bones, the use of which is to support the abdominal pouch. These bones stand up from the edge of the pubis on each side of the symphysis. They are, at least in the *kangaroo*, of an elongated, tapering figure. They are connected with

MAMMALIA.

the pubis by ligament, which allows the free extremities of the bones to be moved up and down upon the belly. These bones exist also in the *ornithorhynchus*.

The *tardigrada* have the *ossa ilii* broad, with a large circular *pubis*. The opening of their pelvis is, therefore, very wide, and but little oblique. In these animals, and the *armadillo*, *pangolin*, and *ant-eaters*, the tuber ischii is placed near the sacrum, and in some cases they are even ossified together. In the *ant-eaters*, the *ossa pubis* have no symphysis, but are separate from each other, in which circumstance they resemble the bones of the pubis in birds. It is worthy of remark, that we discern the most frequent analogies of structure between the toothless tribe of mammalia, and the other classes of animals.

In the *ruminating* quadrupeds the surface of the ileum, which in the human subject is internal and anterior, has a contrary aspect, being turned towards the spine. The ischiatic notch excavates the ileum deeply. In the *ox*, *buffalo*, and other strong-backed *ruminants*, the anterior part of the ileum is very large. The spine of this bone, and the tuberosity of the ischium, are discernible under the integuments, and produce that rugged outline of the rump of cattle.

The dorsum of the ileum is very large in the *horse*, as in some of the *ruminants*, and the neck of the bone is very short: in both, the external surface of the ileum is concave.

In the *elephant*, the surface of the ileum next the belly is hollowed; the crista is round: both the anterior portion of this bone, and that which unites with the ischium, are very large, and the latter most so. The *rhinoceros* has a similar pelvis, but the posterior branch of the ileum is less in proportion.

There is a similitude in the pelves of the swimming quadrupeds, as the *seal*, *otter*, &c. they are long and narrow.

In the *cetacea* there are two bones on each side of the anus. They are conjoined by cartilage before that aperture. These bones have a good deal the figure of two flat short horns united at their root. The ends of the horns are directed towards the spine, and correspond to the *ossa ilii*: near the root there are two small conical projections which supply the place of the ischium of each side, and the conjoined parts of these bones represent the pubis. These bones are suspended in the flesh, and have no connection with the spinal column, and do not form any cavity; they, therefore, properly do not constitute a pelvis. Their use is to give attachment to the penis and clitoris, and some of the muscles of these parts. Cuvier states, that the pelvic bones of *cetacea* are not united to each other, but we have found them as above described in the *grampus*.

The *os femoris*, in the *monkey* tribe, resembles the same bone in man. It, however, is smoother and rounder, having scarcely any *linea aspera* upon it.

In quadrupeds, generally, the femur has a shorter neck, and the great *trochanter* is less eminent, and the bone altogether is shorter in proportion to the other parts than in man. The femur is particularly short in the quadrupeds that have a long *metatarsus*, as the *cattle* and the *horse*. In these the bone is enveloped so much by the flesh of the buttock, that the part which is really the leg is commonly called the *thigh*. This bone is also remarkably short in the swimming quadrupeds, as the *otter*, *beaver*, and *seal*. In the last, Cuvier says the articular extremities make more than half its length. The bone does not appear to be quite so short, according to our observation.

Some quadrupeds possess a hook-shaped process upon the external side of the femur. It has been observed in the

tapir, *rhinoceros*, *armadillo*, and *beaver*. It is the termination of a prominent ridge of the bone about the middle. In the *rhinoceros* this unciform process and the great *trochanter* are much prolonged, and close again, so as to have a hole between them and the body of the bone.

The bones of the leg are very similar in the *monkey* kind to those of the human subject. In some species the tibia is a little bent anteriorly, and more round in its shape.

In the *lats* the *fibula* is a delicate bone. The position of the bones of the leg is changed in these animals. The thighs are directed backwards, by which means the fibular, or external side of the leg, is situated internally.

The *tibia* in the *bear* is a little bent forwards: the anterior tuberosity is very prominent, and the surfaces for articulation with the femur are placed far back.

The position of the fibula is posterior in the *saligrada*.

In the *opossum* tribe, the *long-tailed manis*, the *armadillo*, and the *solb*, the fibula is large and curved outwards, by which some space is left between it and the tibia.

The fibula has a singular formation in the *wombat*, which has been described by Mr. Brodie. It is proportionably larger, he says, than in other animals. At the upper extremity it is broad and has two distinct articulating surfaces; the anterior of which is joined to the tibia, and the posterior to a small bone of a pyramidal shape, which is connected to the tendon of the external head of the *gastrocnemius* muscle, like a *sesamoid* bone. The lower extremity of the fibula is large, and forms about half of the articulating surface for receiving the *tarfus*. An inter-articular cartilage is here interposed between the tibia and fibula, and there is another between the fibula and the *tarfus*. The fibula has a slight degree of motion on the tibia at its upper end, and a half rotatory motion on it at its lower end. Mr. Home supposes, and we think with great probability, that this rotatory motion of the bones of the hind leg is designed to enable the animal to bury itself in the ground.

The fibula in many quadrupeds declines in size, and is ankylosed with the tibia, in which there is an analogy between it and the *ulna* in the fore-arm.

It is united to the tibia for about the lower third in the *mole*. It is connected to the tibia the whole length posteriorly in the *dog*. It is ossified with the tibia at the inferior third of the bone in the *rat* kind. The fibula is flat, and united throughout by ossification with the tibia, in the *elephant*, the *rhinoceros*, and the *hog*. There is merely a rudiment of the fibula in the *horse*, which is ankylosed with the top of the tibia after a certain age.

In the *cloven-footed* quadrupeds, there is a small bone situated on the external edge of the *astragalus*. It forms the external *malleolus*, and is the only vestige that exists of the fibula in this tribe of animals.

The bones of the *tarfus*, and *metatarsus*, are analogous in their varieties to the *carpus* and *metacarpus* of the fore-arm of the same animals.

The hind-foot of the *monkeys*, *lemurs*, and *opossums*, are really hands: the *metatarsal* bone of the great toe is, therefore, shorter than the rest, and capable of being moved outwards. The projection of the *os calcis*, which forms the heel, and is so useful to some quadrupeds in walking, is also diminished in these animals, with the exception of the *Batavian pongo*. There are other peculiarities in their *tarfal* bones. The articulation of the *astragalus* with the bones of the leg is so constructed in the *monkey* tribe, that the foot rests more on the external side than what is called the bottom; a position of the member well adapted for its being employed in climbing, but unfavourable in walking.

In the *lemur tarfus* and *lemur galago*, the *os calcis* and *sesamoides*

MAMMALIA.

phoides are extremely elongated, by which the foot assumes the appearance of a hand and fore-arm.

In the *opossum* tribe, the *astragalus* is very small, and articulated almost exactly between the tibia and fibula. The *Virginian opossum* has a little supernumerary bone upon the edge of the first *cuneiform bone*.

The *os calcis* is of a considerable length in the common *bat*. It has a style shape, and is inclosed in the membranes of the wing at that part. In the *vampyre bat*, the part of the bone that forms the heel turns under the foot.

The *os calcis* is much elongated in the *saligrada*, particularly in the *kangaroo*, in which the bone of the heel stands back a considerable way from the tarsus. The *beaver* has the *os scaphoides* in two pieces; one is placed before the *astragalus*, and the other at the internal side of that bone. There is a flat supernumerary bone upon the inner edge of the tarsus. A similar structure exists in the *marmot*. The *scaphoides* is divided also in the *porcupine* and *paca*, but the supernumerary bone is wanting. In the *squirrel* it is divided, but the inner portion is small. In all this order of quadrupeds, the *scaphoides* forms a tubercle in the sole of the foot. This, in some species, is very long, as in the *jerboa* of the *Cape*, &c. Many of the *saligrada*, that have only three or four toes, have some small bones, which are the rudiments of those that are deficient.

In the *three-toed sloth* the tarsus consists of four bones, the *astragalus*, *os calcis*, and the two *cuneiform bones*. There is a depression in the superior part of the *astragalus* for the articulation with the lower end of the fibula, which is of a cone shape. Upon the inner side of the *astragalus* there is a convex articular surface, which rolls upon the outer side of the end of the tibia. The consequence of this sort of joint is, that the foot of the animal cannot be bent or extended in the usual direction, but from the outside inwards. The *os calcis* is articulated with the *astragalus* by a single tubercle, which is received into a depression of the latter bone, which also facilitates the lateral motion of the foot.

The *elephant* has the tarsus and metatarsus both very short. In the *hog* there are three *cuneiform bones*, but in the *tapir* and *rhinoceros* only two.

In the *cloven-footed* order, the cuboides and *scaphoides* are united together, except in the *camel*. There is a small bone on the outside of the *astragalus*, and articulated with the *os calcis*, which takes the place of the fibula, and corresponds with the one described in the fore-foot as supplying the ulna. There are only two *cuneiform bones* in this tribe, and even they are ankylosed in the *camelopard*. The metatarsus is formed of two pieces before birth, as the metacarpus.

In the *horse* the metatarsus, as in the *cloven-footed* tribe of quadrupeds, is called the *cannon bone*. It has, like the metacarpus of the same animal, two styles upon its sides, which are the rudiments of the metatarsal bones, and phalanges of the second and third toes.

In the *jerboa* (*mus sagitta*) and the *mus jaculus*, the three middle metatarsal bones are ossified together, like the common bone of the *cloven* and *solid-footed* quadrupeds.

The orders of *quadrumanous* and *pedimanous mammalia*, as before-mentioned, have the power of moving the great toe in the manner of a thumb. Cuvier thinks the *aye-aye*, or *Madagascar squirrel*, can do so likewise.

The number of the toes on the posterior feet of quadrupeds varies from five to one. The great toe, or pollex, is the first that disappears.

Some of the *digitigrada* have the great toe diminished, and a few, as the *cat* and *dog* genera, have it entirely obliterated.

Among the *saligrada* there is considerable variety in the number of the toes, and the size of the great toe when it does exist.

Many of the *edentata* and the *tardigrada* receive specific names, according to the number of their toes, which in these are always less than five. In the *armadillos* the great and little toe are shorter than the rest.

Amongst the *many-footed* quadrupeds, as they are called, the *elephant* has five toes, the *hog* four, and the *tapir* and *rhinoceros* three.

The *bisulca* have two perfect toes upon the cannon bone, and two imperfect.

The *solipeda* have one perfect and two imperfect: the latter are merely styloid processes.

It is hardly necessary to observe here, that the position of the toes gives the name to two orders of mammalia. Their number, and their sustaining the animal in walking, or not, determine the character of several natural tribes of this class: the titles we have used for the orders of mammalia throughout the present article, are of themselves explanatory of their foundation: for more full information, see the article CLAS-SIFICATION.

In Plate X. of the *Anatomy of Mammalia*, there are figures given of the three most dissimilar skeletons found in the class. Fig. 1. is a front view of the skeleton of the *bat*, which is taken as the example of a flying species. Fig. 2. represents the skeleton of the *mole*, the mechanism of which is the most curious found amongst quadrupeds. Fig. 3. exhibits the skeleton of the *porpoise*, as an instance of the aquatic tribe of mammalia. In each of these figures similar letters are employed to indicate similar parts, but when any of these parts are out of view, or do not exist in the skeletons, the corresponding letters are of course omitted: *a* is the lower jaw; *b*, the upper jaw; *c*, the inter-maxillary bone; *d*, the malar bone; *e*, ossa nasi; *f*, lacrymal bone; *g*, sphenoid bone; *h*, temporal bone; *i*, os frontis; *j*, parietal bone; *k*, occipital bone; *l*, cervical vertebrae; *m*, dorsal vertebrae; *n*, lumbar vertebrae; *o*, sacrum; *p*, caudal vertebrae; *q*, supernumerary bones on the lower surface of the tail; *r*, sternum, which is singularly formed in the *bat* and *mole*; *s*, ribs; *t*, the clavicle, enormously thick in the *mole*; *u*, the scapula, greatly elongated in the *mole*; *v*, the humerus, short in the *porpoise*, almost square in the *mole*; *x*, the ulna, with an enormous olecranon in the *mole*; *y*, the radius, which makes the single bone of the fore-arm in the *bat*; *z*, the carpus; *1*, the metacarpal bones; *2*, the digiti, prodigiously elongated in the *bat*; *3*, the supernumerary bone of the hand in the *mole*; *4*, the os innominatum: the bones corresponding to the pelvis are very singular in the *porpoise*; *5*, the femur; *6*, the tibia; *7*, the fibula; *8*, the tarsus; *9*, the metatarsal bones; *10*, the digiti of the posterior extremity. There are no bones analogous to those of the posterior member in the *porpoise*.

Muscles.—The *muscles* of the head and face are formed upon different plans in man and mammalia. In the former, besides moving the eye-brows, ears, cartilages of the nose, and lips, they are designed to exhibit the various expressions of human sentiment. But in the latter, the muscles of these parts are almost exclusively confined to those motions which arise out of the mechanism of the organs of sense in different kinds of animals, and are consequently very different in their formation: thus, some mammalia have the external ears greatly developed, others the nose, and others the lips.

The *occipito-frontalis* muscle exists in the *monkey*, *dog*, and other genera, without any remarkable variety, except that it is thinner.

The *corrugator supercilii* also is found in these animals: *Monkeys*

MAMMALIA.

Monkeys very frequently move the skin of the forehead, and frown, without however seeming to intend to express the same feelings which these actions indicate in the human species.

The muscles of the cheeks and lips, which give the principal expressions of countenance in man, are often weak and indistinct in mammalia, or rather replaced by a layer of muscular fibres, resembling the *panniculus carnosus*.

In the *monkey*, the subcutaneous muscle of the face arises from below the orbit and the zygoma; it is continuous with the cutaneous muscle of the neck. It envelops longitudinally the snout, and terminates on the two lips, which it opens. Below this expansion of muscle the *buccinator* is very distinctly found, particularly in those species that have jaw-facts. There are also to be perceived a *levator anguli oris*, an *orbicularis oris*, and sometimes a *fasciculus* corresponding to the *zygomaticus*.

In the *dog*, the upper lip is moved by an expansion of muscular fibres which comes from the anterior angle of the eye, and spreads all over the upper lip, and by another little muscle which descends from the ala of the nose, near the septum in the middle of the lip. Beneath this layer there are found the *orbicularis* and *buccinator*. The lower lip is depressed by a very thin muscle.

The *ruminating* and *solid-footed* quadrupeds have the muscles of the lips large and distinct. In the *sheep* Cuvier reckons seven of them; *orbicularis*, *depressor labii inferioris*, *buccinator*, a very large *zygomaticus*, the *levator anguli oris*, a *nasalis* of the upper lip, and a *subcutaneous expansion* of fibres arising in the neighbourhood of the orbit, and spreading over the *buccinator*.

In the *horse*, in addition to these, with the exception of the two last, there are the *levator labii superioris*; the *pyramidalis* of Bourgelat, or *supramaxillo-nasalis magnus* of Girard; a peculiar muscle for raising the angles of the lips, and a short muscle to each lip, that are called by Bourgelat *medius superior*, and *medius inferior*. It is unnecessary to give any detailed account of these at present, as they are mentioned again, and are described under the *ANATOMY of the horse* in this dictionary.

These animals require an extensive and varied action of the lips as organs of mastication, but the form of their face in other respects prevents their having much expression of countenance.

The *muscles of the nose* are subject to considerable variety in mammalia. In the *monkey* they appear to have their place supplied by the subcutaneous muscle already mentioned.

In the *digitigrada*, of which we take the *dog* as an example, the *levator labii superioris* *aque nasii* is spread over the whole cheek, in a manner similar to the subcutaneous muscle of the *monkey*.

When the cartilages of the nose and the lips are prolonged together, to form a snout, the muscles have a peculiar form and arrangement.

In the *mole*, the muscles which move the snout are eight in number, four on each side. They all arise from above the ears, and send off each a long tendon to the snout. The two deepest seated of these muscles furnish the tendons to the superior part of the snout, upon which they unite and form a broad aponeurosis that covers it for some distance. The two tendons that belong to the most superficial of the muscles unite in a band upon the inferior part of the snout. All the tendons are ultimately inserted into the elastic fleshy disk, which terminates the cartilaginous tube of the snout. In addition to these there is a small muscle that arises from the alveolar edge of the intermaxillary bone, and depresses the snout. There are annular muscular fibres surrounding those

already described: these seem to be the continuation of the *orbicularis oris*.

The muscles of the snout in the *hog* are similar to those of the *mole*, but they are shorter, and arise from different places. The first two come from the lachrymal bone: their tendons do not unite. The next four arise from the superior jaw before the zygoma; the two last are small, and arise from the ossa nasi: their tendons are not joined. There is also the circular muscle, as in the *mole*.

The proboscis of the *elephant* is moved by a very complicated muscular apparatus, of which the best and latest description has been given by Cuvier, in the additions to the 5th vol. of his "Anatomie comparée." It was composed from the dissection of two *elephants*.

He divides the numerous muscles found in this organ into two principal orders; *viz.* those which form the body, or interior part of the trunk; and those which envelope it. The first order are more or less transverse, and intersect the internal part of the proboscis in various directions. The second have more or less of a longitudinal course, or that from the base to the point of the proboscis.

Cuvier again divides the longitudinal muscles into *anterior*, *posterior*, and *lateral*. The *first* arise from the anterior part of the os frontis, above the cartilages, and proper bones of the nose, by a large femicircular line, which descends on each side as far as before the orbits. They form an innumerable multitude of fasciculi, which all descend parallel to each other; and are contracted by tendinous interfections occurring at very short distances. The *posterior* division of the longitudinal muscles arise from the posterior surface, and inferior edge of the intermaxillary bones. They form two layers, each of which is divided into a multitude of little fasciculi, which have an oblique direction. The fibres of the external layer are directed from above downwards; those of the internal take a contrary course, that is, from without inwards; and the fasciculi of the two layers, when they meet, form a middle line, which extends along the middle of the under part of the proboscis throughout its whole length. Finally, the longitudinal muscles that make the *lateral* division form two pairs, of which the one is in some measure a continuation of the *orbicularis oris*, or it might perhaps be rather considered as analogous to the nasal muscle of the upper lip; it comes from the commissure of the lips, and descends between the anterior and posterior muscles as far as the middle of the proboscis; it soon divides into several slips, which are inserted obliquely between the lateral fasciculi of the inferior muscles. The second lateral muscle is analogous to the *levator labii superioris*; it arises from the anterior edge of the orbit, and proceeds, becoming broader, to be spread over the root of the preceding.

Blair has considered the zygomatic muscle as a continuation of the first of these lateral muscles; and because the sterno-cleido mastoideus is attached to the zygoma also, in consequence of the want of the mastoid process, Blair thought that these three muscles were but one, and therefore pretended that the depressors of the proboscis came from the sternum.

The use of the longitudinal muscles of the *elephant's* trunk is sufficiently plain. When they all act together, they shorten the whole proboscis. When those of one side act, the trunk is bent towards that side. The divisions and tendinous interfections of the anterior longitudinal muscles, enable the animal to put particular parts of the trunk into a contracted or bent state, whilst other parts are elongated, or even bent in a different direction, and thus the prodigious variety

variety of forms and curvatures that this wonderful instrument assumes can be accounted for.

Perrault supposed that the interior transverse muscles proceed as rays from the circumference of the two canals to the external surface of the trunk. Cuvier has shewn this to be incorrect. Those of the anterior part proceed nearly like radii from the centre to the circumference; in the region of the axis behind the two canals there are some fasciculi which pass directly from right to left; these are surrounded by others, which go more or less obliquely to the circumference. It is easily perceived that the first and last tend much to diminish the diameter of the external envelope of the trunk, without abridging the capacity of the canals: but when the muscles of the region of the axis are put into action, they contract at the same time the canals and the external envelope. These last series of muscles appeared not to have been known by Perrault; and Stukely did not describe them, although he delineated them in his figure of the *elephant's* trunk.

All these little muscles which form the body of the proboscis are very distinct from each other, and terminate each in slender tendons, of which some pass through the layers of the longitudinal muscles to gain the external envelope, and others go to be inserted into the membrane of the canals. All these muscles are imbedded in a cellular tissue uniformly filled with a white and homogeneous fat.

The transverse muscles are evidently the antagonists of the longitudinal, and in contracting the trunk they also elongate the whole, or parts of it, according to the animal's pleasure.

If the number of short muscles be reckoned as they appear on a transverse section of the proboscis, and if the breadth of a line which is more than their thickness be allowed for the succeeding ones, the total number may be in some degree calculated, which, when added to the number of fasciculi composing the longitudinal layers, will amount, Cuvier says, to between 30 and 40,000. The strength, the variety, and the delicacy of the motions of the *elephant's* trunk, far surpass those of any other organ with which animals are endowed, and are fully explained by the muscular structure above described. The astonishment of the vulgar in seeing *elephants*, that are exhibited by show-men, use their trunk in the manner of a hand, arises from their conceiving this most wonderful instrument to be nothing but a common prolongation of the snout, which, in quadrupeds, generally is a part incapable of performing any considerable motion.

The proboscis of the *tapir*, although much shorter than that of the *elephant*, is formed upon the same plan. The longitudinal muscles are in two fasciculi, and take their origin below the eye. The transverse muscles are attached to the membrane covering the tubes, and to the external envelope, as in the *elephant*; but the *tapir* has an additional muscle, similar to the *levator labii superioris* of the *horse*. It arises from the neighbourhood of the eye, and unites above the nostrils in a common tendon with the same muscle of the other side. The *occipito-frontalis* in the *tapir* also sends off a tendon to the base of the proboscis, which is thereby elevated.

The muscles of the nose in the *cloven-hoofed quadrupeds* are two on each side. They arise from the inferior part of the os maxillare superioris above the anterior molar teeth. Two of them are superior, and two inferior; the first send off each two tendons, one to the upper edge, and the other to the posterior angle of the nostril. The muscles divide each into three portions; they are all inserted into the inferior edge of the nostril.

There is also a muscle for depressing the nose; it is situated anteriorly.

The muscles which operate upon the nares of the *solipeda* are much more complicated than in the preceding tribe. The false nostril is dilated by a muscle which veterinary anatomists have called the *pyramidalis*. It arises from the upper jaw, near the anterior part of the zygoma, by a small tendon. Its fleshy part becomes broader, and expanded upon the convexity of the false nostril, and in the orbicularis oris. There is another muscle situated above the preceding. It arises from the maxillary bone near to the notch of the osseous part of the nares; it penetrates into the fold placed between the bone and the false nostril, and is inserted into a cartilaginous production of the inferior turbinated bone. The femilunar cartilage is made to approach the septum, and the nostril is dilated by a muscle which is common to both nostrils. This is the *transversalis* of Bourgelat. It appears to be an extension of the orbicularis oris. Superiorly there are some fibres which arise from the nasal bone, and are inserted into the superior convexity of the false nares; these are the *brevis* of Bourgelat. There is another muscle called *maxillaris* by Bourgelat, which arises from all the anterior part of the forehead, proceeds obliquely downwards, and divides into two branches. The external passes over the pyramidalis, is intermixed with it, and is inserted in the external convexity of the false nostril.

The *levator labii superioris* also acts upon the nostrils: it arises from the lachrymal bone. Its tendon unites with the one of the other side, to form an aponeurosis, which covers the end of the nose, and is inserted into the upper lip.

The muscles which move the external ear in quadrupeds are much more numerous than in man. In the description which Cuvier has given from the *horse*, *sheep*, *rabbit*, and *dog*, he reckons twenty-one, some of which are peculiar to certain quadrupeds only. He divides them into four classes: 1st. Those which pass from the head or neck to the third cartilage of the ear of quadrupeds, which he has called the *scutum*. The 2d are those which arise from some of the parts of the head, or the cervical ligament, and are inserted into the concha or its tube. The 3d class contains muscles which unite the scutum to the concha, or to the tube of the ear. The 4th class consists of those that extend from one part of the concha to another.

In the first class there are three muscles: the *vertico-scutalis*, the *jugo-scutalis*, and the *cervico-scutalis*. The first comes from the crown of the head, and draws the ear upwards and inwards. The second arises from the zygoma, and draws the ear forwards and a little upwards: it is wanting in the *bare* and *sheep*. The third comes from the cervical ligament, and makes the one ear approach the other posteriorly: it is peculiar to the *dog* and *rabbit*.

The second class contains several muscles.

1. The *vertico-auricularis* arises from the vertex of the head, and is inserted on the concha, which it elevates and approximates to the other: it is peculiar to the *horse* and *sheep*.

2. The *supercilio-auricularis* takes the place of the preceding in the *bare* and *dog*. It arises from the superciliary arch.

3. The *cervico-auricularis* arises from the cervical ligament, and is inserted upon the concha, which it pulls backwards and to the other side.

4. The *occipito-auricularis* passes from the occiput to the concha, which it draws upward and backward: it is not found in the *bare*.

5. The *cervico-tubalis profundus* passes from the cervical ligament

ligament to the tube of the ear, which it draws backwards: it is double in the *horse*, and wanting in the *hare*.

6. The *occipito-auricularis rotator* arises from the occiput, and terminates in the concha, near its tube: it exists in all long-eared quadrupeds, and turns the ear upon its axis.

7. The *parotido-auricularis* passes from the parotid gland to the concha, near the tragus: it depresses the ear, and is a muscle constantly found.

8. The *jugo-auricularis* goes from the zygoma to the concha: it is large in the *sheep*, double in the *dog* and *horse*, and does not exist in the *hare*.

9. The *jugo-auricularis profundus* arises from the posterior part of the zygoma, and is inserted into the concha, near the tube: it shortens the tube.

10. The *vertico-auricularis rotator* goes from the vertex of the head to the anterior part of the concha, near the tube: it rotates the ear, so as to bring the hollow part forwards and inwards.

11. The *vertico-auricularis profundus* arises along with the preceding, and is inserted into that part of the concha nearest the tube, which is inward when its concavity is directed outward: its use appears to elongate the tube of the ear. These last two muscles Cuvier only found in the *horse*.

The third class contains two superficial and one deep-seated muscle.

1. The *scutalis anterior* passes from the lower edge and anterior angle of the scutum, to the front of the concha: it turns the latter on its axis, and directs it upwards and forwards when horizontal. It does not exist in the *dogs* that have hanging ears.

2. The *scutalis posterior* has nearly the same origin as the preceding, but is inserted into the back of the concha: it raises the concha. The *hare* wants this muscle.

3. The *scutalis rotator* is deep-seated, and arises under the scutum, and terminates behind the concha next the tube: it rotates the concavity of the concha towards the earth, and backwards, when it is horizontal. This muscle is double in the *hare*.

The fourth class of the muscles of the ear do not exist in the *sheep*; and there is only one of them in the *horse*, which is the *tragicus*: it contracts the opening of the external meatus. It is found in the *dog* and *hare*.

In the *hare* there is a muscle which shortens the tube: it is called by Cuvier *tubo-helicus*.

In the *dog* there is a muscle analogous to those on the helix in the human subject. Cuvier calls it *plicator auris*.

In the *dog* and *horse* there are some muscular fibres upon the back of the concha, analogous to the *transversus auris*.

By means of the muscles above described, quadrupeds are enabled to give almost all possible attitudes to the external ear, besides collecting the sounds which approach in various directions. The external ear is sometimes employed in expressing the sensations of animals: thus, *horses* throw back their ears, when displeased; and most quadrupeds shew their satisfaction by an erect position of those parts.

The muscles which move the jaws in mammalia are, except in some of the *saltigrada*, the same in number, and bear the same names as those in man. They differ chiefly with respect to their relative strength. This circumstance has been in a great measure already explained, in describing the form and extent of the bones to which these muscles are attached.

As a general observation, it may be stated, that the *masseter* and *pterygoid* muscles are largest in the *herbivorous* quadrupeds, and the *temporal* in the *carnivorous*.

In the *ant-eaters*, the position of the *masseter* is very unfavourable to its action.

The tubercle that supplies the place of the zygoma is anterior to the part of the lower jaw, to which the other extremity of the *masseter* is affixed; consequently the fibres of the muscle pass in a direction contrary to that in which their force is exerted.

In the *mus typhlus*, the *temporal* muscle is very strong, although it is thin in this tribe generally. The *typhlus* has it so much extended as to be intermixed with the one of the opposite side, upon the upper part of the head.

The *mole* has the *temporal* muscles very thick and elongated, so that their greatest extent is from behind forwards. They touch each other upon the crown of the head.

In the *carnivorous digitigrada*, especially the *cat* genus, the *temporal* muscles have so great a bulk in every direction, that they make up the chief part of the bulk of the head.

An additional muscle on each side, for raising the lower jaw, has been discovered in the *cavy*, and other *saltigrada*, by Mr. J. F. Meckel, which is designed to aid these animals in their particular mode of comminuting their food. This muscle has received the name of *mandibulo-maxillaris*. In the *cavy* it commences as a thick mass, from the most anterior part of the superior maxillary bone, proceeds backwards and downwards across the great sub-orbital foramen, which it fills, and changes there into a strong tendon, which descends to the lower jaw, to be inserted on the outside of the *pterygoideus externus* muscle, opposite the first molar tooth, that is, in the most anterior part of the canal, in which the *pterygoid* muscles are inserted. These muscles are generally similar in the other *gnawing* quadrupeds: they are muscular throughout in the *rats*, in whom they are very strong. The action of the *mandibulo-maxillaris* muscle has a direct effect upon the incisor teeth, or upon the extremities of both jaws; and hence the existence of this muscle in those *saltigrada* that gnaw hard substances. The *mandibulo-maxillares* are wanting in the *hare* and *marmot*, which live on soft herbs.

The *diaphragic* muscle, except in the *monkey*, is differently formed than in man. The name of *masso-maxillaris*, imposed upon it according to the modern system of nomenclature, is peculiarly proper. It generally wants the middle tendon, which forms it into a muscle with two bellies, or a *diaphragic*. In the *mandril* (*simia maimon*), the tendons of the mastoid portions of each side become intermixed above the *hyoides*, so that these two portions appear to make a *diaphragic* muscle.

In the *digitigrada* this muscle has but one belly, and it is inserted into a process at the posterior angle of the branch of the jaw.

In the *saltigrada* there are two portions.

This muscle is wanting in the *ant-eaters* and *armadillos*. These animals have its place supplied by a long slender muscle, that arises from the middle of the top of the sternum, and is inserted at the inferior and middle part of the ramus of the lower jaw. This muscle is called by Cuvier the *sterno-maxillaris*.

In the *stothes* the *diaphragic* is connected with the *sterno-hyoides* muscle.

The *ox* has the middle part of this muscle covered above and upon the internal edge by an aponeurosis, which gives attachment to a square muscle, that extends from one *diaphragic* to the other.

The muscles of the *os hyoides* exhibit no very striking peculiarities, except in some of the *edentata*.

The *sterno-hyoides* muscles in the *lion* arise so far within the sternum as the third piece composing that bone. In the

MAMMALIA.

feal they arise from the first ribs, and are strengthened by a slip from the little tuberosity of the humerus, which corresponds to the *omo-hyoideus*. The sternum is narrow in those animals, to which Cuvier ascribes the sterno-hyoideus as having an unusual origin.

The *sterno* and *omo-hyoidean* muscles are incorporated, and make a very large muscle in the *dolphin*.

The *stylo-hyoideus* is only perforated by the digastric muscle in the *monkey*, as in man.

In the *paca* the *stylo-hyoideus* is wanting: the styloid bone is not connected with the cranium; and the middle portion of the digastricus adheres firmly to the body of the os hyoides.

The *mylo-hyoideus* is an active muscle in bringing forwards the hyoides, when this bone is placed far back, and the jaw is much elongated.

The position of the os hyoides being so near the sternum in the *ant-eaters*, the muscles which act upon it have many peculiarities. There is a very small muscle which is analogous to the *stylo-hyoideus*: it arises from the middle and anterior part of the styloid bone; it descends inwards and backwards, to be united to the edge of the *genio-hyoideus*. The *mylo-hyoideus* is necessarily very long: it does not touch the os hyoides, but its last fibres ascend to the base of the styloid bone, to which they are affixed; and, more anteriorly, some of these fibres even ascend to be inserted into the transverse processes of the middle cervical vertebræ. Those which precede the last mentioned are inserted more internally, into the membrane of the bottom of the mouth. It is only the portion corresponding to the two anterior thirds of the jaw, that is attached to the edge of that bone. There is no middle tendinous line in this muscle, and all its fibres are transverse in their direction. The *genio-hyoideus* is a single muscle: it is attached to the angle of the chin by a very thin tendon, which extends to the opposite angles of the jaw, accompanying the middle of the *mylo-hyoideus*: its fleshy part commences there. It is very thin throughout, and is at first narrow, but it afterwards enlarges, and then is composed of two portions: it contracts again, before it is attached to the body of the hyoides. The *sterno-hyoidei* muscles extend upon the sternum, as far as the middle of the bone.

In the *echidna* the *mylo-hyoideus* is attached in a great measure to the palatine membrane: the most distant portion ascends upon the sides of the occiput.

In the *ornithorhynchus* the *mylo-hyoideus* has a tendinous line in the middle, from which the muscular fibres depart on each side, and proceed obliquely from behind forwards, and are inserted into the inferior border of the jaw. There is a second portion of this muscle, which appears to supply the place of the *genio-hyoideus* in this animal. Its fibres depart from the hyoides and the base of the tongue, and advance more obliquely outwards, as far as the most distant part of the branches of the jaw, to the lower edge of which they are attached. The *sterno-hyoideus* is prolonged upon the sternum, as far back as the middle of that bone, both in the *echidna* and *ornithorhynchus*. It is difficult to conceive the use of the extension of the muscle in the latter animal. In the *echidna* and the *ant-eaters* it is subservient to the motions of their tongue.

The muscle called by Cuvier *stylo-mastloideus* is peculiar to mammalia, in which it appears to exist pretty regularly. It is a small muscle, arises from the external surface of the mastoid process, and is inserted upon the internal surface of the temporal end of the styloid bone. When the styloid bone, as in the *cloven-hoofed quadrupeds*, has an angle prolonged

posteriorly, this muscle is inserted into it, and moves the styloid bone as a lever, and brings its lower end upwards and outwards. When the styloid bone is not attached to the cranium, this muscle serves to suspend it.

In the *paca*, the *stylo-mastloideus* seems to form a part of the digastric, with which it descends to the os hyoides, and is afterwards extended upon the sides of the pharynx, by which it supplies the place of the *stylo-pharyngeus*.

In the *digitigrada*, there is another additional muscle: it is thin, flat, and fills up a part of the interval of the two horns of the os hyoides of the same side.

The muscles of the pharynx resemble those of man so much, that a description of them becomes unnecessary.

There is a *pharyngeus proprius* in the *elephant*, *bear*, &c. which has been already mentioned.

The *stylo-pharyngeus* has some peculiarity of direction and effect, in consequence of the horizontal position of the pharynx. It descends almost perpendicularly from the styloid process, or bone, upon the upper surface or sides of the pharynx, and it is only after it has passed under the constrictor muscles that it proceeds backwards along the pharynx. Its operation is rather to dilate the bag of the pharynx than to bring it forwards.

The peculiarities of the muscular structure of the tongue are already noticed in the first part of this article, where that member is described as an organ of mastication.

The *subcutaneous muscles* are much more remarkable in quadrupeds than the human subject. In the latter, they are weak, and confined to particular places; but in the former, almost the whole of the skin can be moved; and in those species that roll themselves up when they are in danger, the subcutaneous muscles are of great magnitude, and complicated in their arrangement.

The *cutaneous* or *latissimus colli*, (*thyrago-facialis* of Cuvier) is inconsiderable in many quadrupeds. It is intermixed with some muscular fibres that lie under the skin of the face in the *monkey* kind, as already observed. In the *marmot*, this muscle has another placed under it, which is thicker, and extends to the side of the head, and to the face and snout.

There is a cutaneous muscle upon the abdomen, and under the skin of the thighs of quadrupeds, which is inserted, along with the pectoralis major, into the humerus by one or two tendons. Besides acting upon the skin of the lower surface of the body, it concurs, with the actions of the pectoral muscle, in bringing the arms inwards, and in the true quadrupeds is a muscle of progression, by assisting to move the body forwards upon the anterior extremities. Cuvier gives the name of *dermo-humeralis* to this muscle. In the *racoon* it is attached to the prepuce, which it retracts. Where it covers the belly of this animal, it is very thin. In the *marmot* this muscle covers the back as well as the under surface of the body: it is inserted into the arm by two tendons; the one with that of the *latissimus dorsi*; the other with the tendon of the pectoralis major.

Those animals that have the power of rolling themselves up, possess a number of curious muscles for the purpose. These are the most numerous and striking in the *badge-hog*.

In this animal there is a very extensive subcutaneous muscle upon the back of the body. Its fibres adhere closely to the skin of the back and the ends of the spines. The shape of the muscle is oval: the middle of it is thin, and has the fibres mostly arranged longitudinally; but around the edge they are thick, and have a circular direction, and resemble a sphincter muscle.

In the ordinary position of the *badge-hog*, the dorsal muscle is contracted, and entirely carried upon the back; but when

MAMMALIA.

when the creature is coiled up, the longitudinal fibres of the muscle are so much relaxed, that it is capable of being extended over the top of the head, the tail, and posterior legs; after which the sphincter or marginal fibres are put in action, by which the whole body is inclosed, as it were, in a round bag.

There are several small distinct muscles which serve to connect this fleshy oval expansion to different parts of the body, and which contribute to bring the head and limbs into their proper position, after they have been doubled up by the muscles situated upon the inferior part of the body. Two pair of these muscles arise from the anterior extremity of the oval muscle. They are inserted into the nasal and intermaxillary bones, and the lateral parts of the nose.

One pair of muscles arises from the posterior part of the oval expansion; they are broad, pyramidal, and inserted by tendon into the sides of the tail, near its end.

There are three distinct portions of muscles under the skin, upon the lower surface of the body. The first corresponds to the cutaneous colli: it arises from the top of the sternum, and is inserted behind the ears. The second is posterior to this; it arises from the middle of the sternum; it passes over the top of the shoulder, and is inserted into the oval or orbicular muscle of the back. These two muscles, with their fellows of the opposite side, produce the figure of two cones, having their points turned backwards, and the one being received into the base of the other. The third muscle covers with its fellow the surface of the abdomen. It is attached to the tail, the top of the thighs, the arm, and the dorsal muscles, by so many distinct slips or divisions. This muscle is analogous to the *dermo-humeralis* of other quadrupeds.

There are, besides those already described, some deep-seated muscles situated under the great oval one of the back. One arises from the posterior edge of the meatus auditorius externus, and proceeds backwards to be lost in the fore-part of the orbicular muscle. Another arises from the last cervical vertebræ, and is also inserted into the orbicular muscle. Underneath the great oval muscle there is a thin layer of transverse fibres: the anterior ones are attached to the inner and upper part of the humerus, and the posterior to the external process of the ventral or *dermo-humeralis* muscle.

When the orbicular muscle is entirely contracted, and carried upon the back of the *hedge-hog*, it serves as the fixed attachment of the muscles, which go from it to the head, neck, and tail; and these parts are consequently raised or sustained by them; but when the animal wishes to roll itself up, it relaxes the orbicular muscle, and puts into operation the flexors of the head and limbs, by which they become fixed points, and all the straight muscles connected with the oval or orbicular muscle of the back are enabled to act upon it, and spread it over the body; and when the latter is brought over the head and tail, the margin of it contracts separately from the rest, by which even the head and feet of the animal are completely inclosed. The connection which the great oval muscle has with the roots of the spines of the skin, puts the spines into a state of erection in different directions, which renders the animal unassailable at every point. See Himly's account of the rolling up of *hedge-hog*, printed at Brunswick, 1801, 4to.

The muscles that act immediately upon the ribs have no peculiarities in mammalia worth remarking.

The abdominal muscles are longer and narrower in mammalia than man. This depends, in some degree, upon the difference in the shape of the trunk, but not entirely, as

the *straight* and *pyramidal* muscles are generally the most elongated. In many of the *digitated* quadrupeds the *pyramidales* are wanting, and the *recti* extend as far as the anterior part of the sternum.

The *diaphragm* exhibits, in general, no difference of structure in mammalia from what is described in man. According to Cuvier, it has in the *bats* two very strong crura, which form a kind of fleshy septum placed longitudinally on the spine within the abdomen.

Those animals that have an abdominal pouch for containing the mammæ and the young during the period that they are suckled there, have two additional bones attached to the pelvis, as already mentioned. These bones are moved by two muscles, long since described by Tyson, and called by him *triangulares*. These fibres arise in different directions from the side of the marsupial bones next the symphysis pubis, and both muscles unite with each other, in the middle of the interval, between the two bones, by means of a tendinous line. These muscles sustain, elevate, and approximate the marsupial bones, in doing which they are assisted by the abdominal muscles, which are likewise connected with these bones. The muscles which move the head upon the spine, and the different vertebræ upon each other, exhibit but few deviations from the structure described in man, that are worthy of remark.

In most mammalia, the *obliquus capitis inferior*, and the *rectus capitis poslicus major*, are much larger than in man, in proportion, on account of the magnitude of the two first vertebræ of the neck being greater. The *monkey* and *cetaceous* tribes, however, form exceptions to this observation.

The *biventer cervicis* is commonly not divided by tendon into two bellies: the new name of *trachelo-dorsalis* given to it by Cuvier is particularly proper. In the *digitigrada* it is intersected by transverse tendons throughout. It is quite distinct from the *complexus*, although it lies upon it. The *horse* has these two muscles joined together at the upper part.

The *splenius* is larger in mammalia than in man, and is particularly strong in the *mole*. In those that have the ligamentum nuchæ elevated above the vertebræ, the *splenius colli* is inserted into it. There is no part of the muscle inserted into the transverse processes of the cervical vertebræ in the *digitigrada*.

The muscles of the dorsal spine conform still more closely in general, than those of the cervical, to the plan observed in man. In the *bat*, however, these muscles are nearly obliterated.

The muscles of the tail, in almost all mammalia, are larger and more complicated than they are in man, but in particular species they are very remarkable for their number, or their strength. Cuvier has reckoned eight pair of muscles in mammalia, but if the portions of which these are composed be counted in any of the long-tailed species, they will be found to be vastly numerous. Mery stated that he met with 280 caudal muscles in a *prehensile-tailed monkey*. The *cetacea* have the muscles of the tail so large as to give to these animals the figure of fishes. The *beaver* has the flexor muscles of the tail prodigiously strong, in order that it may be able to employ that member in the manner of a trowel for plastering its habitation. The *kangaroo* has the extensors very strong, as the animal uses the tail to project the whole body from the ground in its singular mode of progression by leaps.

In describing the caudal muscles we shall follow Cuvier and Vic d'Azir.

The *sacro-coccygei superiores* of Cuvier, or *lumbo-supra-caudales*

MAMMALIA.

caudales of Vic d'Azir, are situated upon the upper side of the tail. They arise, by fleshy slips, from the three or four last lumbar vertebræ, the sacrum, and from those caudal vertebræ that have processes. Small tendons pass off from the common mass opposite to the fleshy digitations. The first tendon is the shortest, and is inserted into the base of the first caudal vertebra. The second tendon to the next vertebra, and so on to the end. There are thirteen of these tendons. They enter ligamentous grooves or sheaths, which are connected together by a ligamentous web that incloses them in a sort of case. These muscles have the effect of directly raising the tail.

The *interspinales* (*spinales obliqui* of Cuvier,) (*lumbo-sacro-coccygei* of Vic d'Azir), should be considered as the continuation of the *inter-spinal* muscles of the back. They cooperate with the last described in the elevation of the tail.

There are four pair of muscles for depressing the tail.

The *ilio-subcaudales* (*ilio-coccygei* of Vic d'Azir) arise from the internal part of the ileum; form two long fleshy masses in the pelvis; and are inserted into one of the V shaped bones of the under surface of the tail. Sometimes they are inserted between the fifth and sixth of these bones, at others between the seventh and eighth.

The *sacro-subcaudales* (*sacro-coccygei inferiores* of Vic d'Azir) resemble exactly the *sacro-coccygei superiores*, except that they are placed upon the opposite side of the tail. They arise from the sacrum, and from the transverse processes of the superior caudal vertebræ. Their tendons are long and numerous, and inclosed in a sheath, like those of the *sacro-coccygei superiores*. They begin in the long-tailed species to be inserted into the seventh caudal vertebra, and so on.

These muscles, with the *superior coccygeal*, operate upon the tail, even to its point, and have exactly the opposite effects of each other. They are particularly employed in all the more delicate motions of the tail.

The *subcaudales* of Cuvier (*inter-coccygei* of Vic d'Azir) are situated under the middle of the tail. They arise at the articulation of the first and second caudal vertebræ. They are first inserted into the V shaped bone of the fourth, fifth, and sixth vertebræ; they further receive little fleshy slips, which gradually diminish, and go on to be inserted into the base of each bone of the tail.

The *pubo-subcaudales* of Cuvier (*pubo-coccygei* of Vic d'Azir) arise broad and thin from the upper part of the pelvis, and proceed to terminate in points which are inserted into the processes or tubercles at the base of the fourth and fifth vertebræ, upon the inferior surface of the tail. They bring the tail close to the body. These muscles are wanting in the *raccoon*.

There are two muscles on each side of the tail for producing the lateral motions of it.

The *ischio-caudalis* of Cuvier (*ischio-coccygeus externus* of Vic d'Azir) arises from the internal surface of the ischium, and passes backwards over the transverse processes of the tail. In the *raccoon*, it is inserted into the seven caudal vertebræ that succeed the third, by seven fleshy digitations. In the *opossum*, into the four first vertebræ of the tail. In the *dog*, it is a mere slip of flesh, and is inserted into the fourth vertebra.

The *intertransversalis* passes from one transverse process to the other on each side, as far as they go. This muscle is similar to the one of the same name in the other parts of the spine.

It is scarcely necessary to observe, that the combined actions of these muscles, or their contractions in opposition to

each other in different parts of the tail, are capable of communicating to this member all possible directions. The effects of this co-operation are strikingly displayed in the tails of certain *monkeys*, *marsupial animals*, *ant-eaters*, &c. in which this member is capable of performing most of the operations of a hand.

There are several peculiarities to be noticed in the *muscles* of the *anterior extremity*, particularly those of the shoulder and upper arm of quadrupeds.

The *ferratus major* has not only the digitated attachments to the ribs, but to some or all the transverse processes of the cervical vertebræ. In the *dolphin*, and probably in all *cetacea*, this muscle has no attachment to the cervical vertebræ; the greater extent of the *ferratus major* appears to be required for progression on four feet.

The *pectoralis minor* does not exist in the *digitigrade* and *hoofed quadrupeds*. Another muscle supplies its place in the *horse*. This is united to the *pectoralis major*, and is in part inserted into the humerus. The *pectoralis minor* of the *dolphin* is narrow, and arises by one digitation from near the top of the sternum, and is inserted at the glenoid cavity of the scapula.

The *levator scapulae* is inserted into the spine of the scapula in the *monkey*, the *digitigrade* and *saltigrade* quadrupeds. In the *dog* and *bear* it arises from the first cervical vertebra only, and in the *rabbit* from the cuneiform process of the caput, and has been called by Vic d'Azir *acromio-basillaris*. In the *sheep* it arises from the first cervical vertebra, and is inserted into the posterior part of the spine of the scapula. The *levator scapulae* is wanting in the *horse*. In the *dolphin* it comes from the first cervical vertebra, and its tendon is spread over the whole external surface of the scapula.

The *trapezius* and *sterno-cleido mastoideus* are generally confounded with each other, or with some of the other muscles of the neck. In the *carnivorous*, and those *saltigrade* quadrupeds that have an imperfect clavicle, the clavicular portions of the *sterno-cleido mastoideus*, and of the *deltoideus* and of the *trapezius*, make but one muscle, to which Cuvier gives the name of *masto-humeralis*, and which has been called by other anatomists *communis capitis*, *pectoris*, and *brachii*. The clavicular portion of the *trapezius* is distinct from the scapular portion; and the *levator scapulae* passes between them. In the *bear*, the anterior portion of the *trapezius* is again divided into two muscles, one of which sends a tendon to the top of the sternum. In the *sheep*, there is a muscle which arises from the mastoid process; it divides into two; one goes to the sternum; and the other is incorporated with the clavicular portion of the *trapezius* and of the *deltoideus*. In the *horse* there is a distinct *sterno-mastoideus*, but the *cleido-mastoideus*, *levator scapulae*, and the clavicular portions of the *trapezius* and *deltoideus*, are supplied by one muscle, which arises from the mastoid process, and the transverse processes of the superior cervical vertebræ, and passes down the internal side of the arm to be inserted inferiorly. In the *dolphin*, the clavicular portion of the *trapezius* is wanting; the *sterno-mastoideus* of this animal is very strong, and there is another muscle external to it, which arises from the mastoid process also, and is inserted below the head of the humerus.

There is a muscle of the shoulder apparently peculiar to the *rabbit*: it is thin, and arises from the spine of the scapula, and is inserted into the clavicle.

The *rhomboides* is a larger muscle in quadrupeds, in proportion, than it is in man. It is even in the *monkey* tribe extended to the occiput. The portion arising from the skull is distinct in the *digitigrade* quadrupeds, and is the

muscle which has been called the *levator scapulae magnus*. This portion of the *rhomboides* arises from the ligamentum nuchæ in the *horse*, and has been called by the veterinary anatomists *levator scapulae proprius*. The *rhomboides* has no division, and is a small muscle in the *dolphin*.

The *subclavius* is of course wanting in those quadrupeds that have imperfect clavicles, or none.

We have reserved the account of the muscles of the shoulder in the *mole* and *bat* for separate consideration, as the motions of the anterior extremity in these animals are so very peculiar.

In the *mole*, the *ferratus major* is extremely large, but simple in its form; it arises from only the last cervical vertebra. The *trapezius* has no anterior origin; there are only two fasciculi from the lumbar region to the posterior angles of the scapulae, which would draw these bones asunder, if they were not bound together by a strong transverse ligament. The *rhomboides* is attached posteriorly almost entirely to this transverse ligament of the scapulae, and anteriorly to the ossified ligamentum nuchæ. The chief use of this muscle is therefore to elevate the head. The muscle corresponding to the occipital portion of the *rhomboides* arises from the middle of the head, has its fibres parallel to the cervical spine, and passes through the *rhomboides*, properly so called, to be attached to the transverse ligament of the scapulae. This muscle operates with great power in raising the head, which is a necessary exertion to the *mole* in burrowing. This animal has two muscles to the clavicle: one of these Cuvier calls *superclavius*: it arises from the first bone of the sternum at the anterior angle of the great head of the clavicle. The other arises lower down on the sternum, and is inserted near the first.

In the *bat*, the *ferratus major* is situated before the *pectoralis minor*. It is only attached to the ribs, and is inserted into the inferior and external edge of the scapula. The *subclavius* is very large. The *trapezius* arises from the eleven first dorsal vertebrae, and is inserted into the triangular surface of the cervical angle of the scapula. The *malloïd* muscle is only attached to the sternum.

The muscles of the humerus appear all to exist in mammalia, but frequently under different conditions than in man.

The *pectoralis major* is commonly composed of several distinct fasciculi, or portions. In those species which have not a perfect clavicle, there is a portion of this muscle arising from the sternum, and inserted into the linea aspera, which, with the portion of the opposite side, makes a common muscle for both arms, to which Cuvier gives the name of *ambibrachialis communis*. It has the effect of crossing the fore-legs. In the *sheep*, there is a second common muscle, which passes from the sternum to the ulna, completely inclosing the humerus with the trunk. It is designed to cross the fore-legs, and has been called by the veterinary anatomists, in the *horse*, *ambibrachialis communis*. It should rather, perhaps, be considered a subcutaneous muscle than a portion of the *pectoralis major*. In the *bat*, the *pectoralis major* is divided into three distinct muscles. The last lies partly under the first. This is inserted into the great anterior tubercle of the humerus. The second is inserted above the first, behind the great tubercle; and the third muscle terminates upon the spine of the humerus. These muscles depress the wing in flying, and therefore require to be very strong.

The *latissimus dorsi* of the *bat* is a fleshy stripe from the spinous tubercles of the two last dorsal vertebrae.

The *supra* and *infraspinatus* of quadrupeds have a different relative size to each other than in man. In the former,

the *supraspinatus* is the larger muscle. In the *cetacea*, the muscles on the back of the scapula are nearly obliterated.

In those species that want the clavicle, there is only the scapular portion of the *deltoides*, the other part being, as before described, continued into the *trapezius*. There is a distinction of two parts also in the scapular portion, the *acromial* and *infraspinatus*. In the *horse*, the acromial attachment is wanting, and the deltoid having the same direction as the *infraspinatus*, it is distinguished by the peculiar name of *abductor longus brachii*.

The *coraco-brachialis* consists of two parts in the *monkey*, *bear*, &c. one of which extends the whole length of the humerus. In the *bear*, the inferior portion is inserted into the external condyle. When there is no coracoid process of the scapula, this muscle arises from a little eminence on the upper edge of the scapula.

In the *dog*, *cat*, *rabbit*, and *horse*, the *biceps* arises by one head, and is unconnected with the *coraco-brachialis*.

In the *bat*, there is no *coraco-brachialis* nor *teres minor*.

The muscles which move the humerus are of an extraordinary bulk in the *mole*. The *pectoralis major* is almost as large as the pectoral muscles of *birds*. It consists of six portions: four of these arise from the sternum, and are inserted into different points of the humerus; the fifth comes also from the sternum, and covers the whole surface of the humerus; the sixth is extended from one humerus to the other. The *latissimus dorsi* is also very strong; it is divided into two parts. The *teres major* is prodigiously strong. Upon these three muscles chiefly depend the rotation and the retraction of the anterior limbs of the *mole*, the motions by which it excavates the earth with such extraordinary force and rapidity.

The *supinators* and *pronators* of the fore-arm are not found in those species of mammalia which either have the ulna immoveable, or obliterated. The *cat* and *dog* have the *supinator brevis*, but not the *longus*. The *rabbit* has only the *pronator teres*.

Monkeys, the *cat*, and *bear*, have the same number of flexors and extensors of the *carpus* as the human subject. In the *eleven* and *solid-hoofed* quadrupeds, the *external radialis* is inserted anteriorly into the base of the cannon bone, which it extends; this is the *extensor reclus anticus* of Bourgelat. The *radialis internus* is the *flexor internus* of Bourgelat. The *ulnaris internus* is the *flexor obliquus* of the same author; it is inserted into the bone that corresponds to the *os pisiforme*. The *ulnaris externus* is inserted likewise into the same bone, and is called by Bourgelat the *flexor externus*. The muscle analogous to the *ulnaris externus* in the *bat*, arises from the *os brachii*, and from the radius as far as its middle. Its tendon is inserted into the upper and internal part of the *carpus*, which it abducts. The muscle corresponding to the *ulnaris internus* arises from a fleshy portion common to it, and the other muscles of the fore-arm, and is inserted into the external side of the first phalanx of the last finger. It adducts the *carpus*. The *adductor pollicis* has the same common origin, and sends its tendon obliquely across that of the *ulnaris externus*, and is inserted into the internal side of the *carpus* at the base of the thumb.

The *extensor communis digitorum* exists in all quadrupeds. Its tendons correspond to the number of fingers. The portion, which merely extends the little finger in man, is of greater size, supplies more fingers, and is more distinct in many mammalia. In the *monkey* and *rabbit* it has two tendons, and sends one to the fourth finger. In the *dog* and *bear* it furnishes a tendon also to the third and middle fingers.

MAMMALIA.

The *cat* has two muscles in place of this division of the extensor communis. In the cloven-footed cattle this muscle extends the outer toe, and the *extensor indicis* the internal.

There are two muscles in the *horse*: one is called by Bourgelat *extensor lateralis*, and by La Folle the *extensor of the pastern*. It sends the tendon to the side of the first joint of the toe.

The other muscle is situated between the preceding, and the one analogous to the *extensor communis*, of which it is considered by some anatomists as making a part.

The *indicator* has two tendons in the *monkey*, one of which goes to the middle finger: this muscle does not exist in the *rabbit*, the *solid* and *cloven-footed quadrupeds*.

The *extensor brevis pollicis* is not found in the *cat*, *dog*, *bear*, and *rabbit*. The *extensor longus* sends a tendon to the first finger in the *bear*.

The *flexor longus pollicis* is wanting in the *monkey*, and its place supplied by a fifth tendon from the *flexor profundus communis*.

In the *dog*, the *flexor profundus* unites with the *flexor pollicis*, and the latter separates to go to the thumb. The *flexor sublimis* sends a tendon to the thumb.

In the *cat*, the *flexor profundus* consists of five distinct slips, and sends off as many tendons. The *sublimis* also sends a tendon to the thumb.

In the *rabbit*, the *profundus* furnishes a tendon to the thumb, but the *sublimis* not.

The flexors furnish fewer tendons, of course, where there are fewer digits; for instance, they send off but two in the cloven-footed, and one in the solid-hoofed quadrupeds. The *bat*, which has so many peculiarities of the anterior extremity, has only one *extensor* of the digits: its fine tendons run along the back of each of the elongated fingers that sustain the membrane of the wing, to the extension of which they contribute. The *flexor communis* arises from the common mass of muscle upon the inside of the fore-arm: its delicate tendons unite with the *flexores proprii* of the joints of the wing. These last muscles are four in number; they form a fleshy mass where they arise from the carpus; become connected with the tendons of the *flexor communis*, and are extended to the ends of the joints of the radii of the wing. Some short fibres arise from the carpus, and are inserted into the root of the pollex.

The muscles of the fingers are obliterated in the *cetacea*.

The muscles of the inferior, or, more properly, posterior extremity, that arise within the body, are, in general, similar in man and mammalia. The *psoas parvus* has been observed to be wanting in the *rat*.

The *bat* wants the *quadratus lumborum*, *psoas magnus*, *iliacus internus*, *pyriformis*, *gemini*, *obturator internus*, and *quadratus femoris*. The *psoas parvus*, is, however, very strong in this animal, and its aponeurosis broad; the *pectineus* and *obturator externus* are long and slender. The *pectineus* of the *dog* sends its tendon to the lower part of the femur. Quadrupeds, in general, have the *psoas magnus* and *iliacus* more elongated in their figure than they are in man.

There is a striking disproportion in the *gluteal* muscles of mammalia. The *external*, called in man *gluteus maximus*, is in all quadrupeds the smallest of the three. In the *horse*, it is little more than an aponeurotic expansion, and is called by Bourgelat the *gluteus minimus*. The diminished size of this muscle, proves that its chief use in the human subject is to move the pelvis upon the thigh, and to maintain the erect position of the body. In the *horse*, this muscle has, in addition to the thin fleshy head from the sacrum and back of the ileum, another thin slip from the top of the ileum.

The *gluteus medius* and *minimus* are found much larger in proportion in quadrupeds than man. The *medius* in the *horse* is very large: it arises from the sacrum, all the membrane between that bone and the ileum and ischium, and is inserted into the process of the femur that Cuvier has been inclined to call a third trochanter. This muscle draws the limb backwards, as in the action of kicking. In the *bat*, the *gluteus minimus* descends almost perpendicularly from the ileum to the femur. This animal has but one *adductor femoris*, or head of the *triceps*: it goes from the symphysis of the pubis to the femur, about one-third from its top.

The shape of the thigh is rather flat in the true quadrupeds, and even in the *monkey* it is less round than in man. The muscles are thrown forwards and backwards, which is the most convenient position for progression on four feet. The great size of the muscles upon the internal part of the thigh of the human subject is not designed, as anatomists generally state, to bring the legs together, or to belstride a horse, or, in case of shipwreck, the mast of the vessel, but in the ordinary progression, on two feet, to transfer the weight of the body from one side to the other.

The *sartorius* and *gracilis* are placed upon the anterior part of the thigh in the *digitigrade* and *saltigrade* quadrupeds. The *sartorius* is called in the *horse* *adductor longus*. The *gracilis* is large in all quadrupeds, and especially in the hooved orders. It is called by Bourgelat the *adductor brevis*. He gave the name of *gracilis* to the muscle corresponding to the *semi-tendinosus*.

This last muscle, and the *semi-membranosus*, are inserted into the tibia by a broad aponeurosis, lower down than in man, by which means the hind legs are always, in a degree, bent, a circumstance favourable to progression on four feet, but very inconvenient in the erect position of the body. Even the *monkey* has this form of the limb, and for that reason, as well as others, cannot remain long standing, without supporting itself by the anterior extremities. In the *bat*, there is one muscle which supplies the place of the *sartorius*, *gracilis*, *semi-tendinosus*, and *semi-membranosus*. It arises by two portions: the one from the fore-part of the ileum, the other from the pubis and ischium. The *adductor femoris* passes between them. The common tendon produced by these two muscles is inserted below the head of the tibia, on what is the fore-part of the leg in the *bat*. This muscle bends the leg. There is but one muscle also for extending it, which arises from the upper part of the femur, and is a slender tendon, which is inserted into the tibia.

The muscles composing the calf of the leg are much smaller in mammalia than man, in proportion to the size of the animals. The *soleus* arises from the head of the fibula: it is peculiarly slight in the cloven and solid-hoofed quadrupeds.

The *tibialis anticus* is inserted into the anterior surface of the lower part of the cannon bone in those quadrupeds that have this bone.

The *tibialis posticus* of the *monkey* has a large sesamoid bone in its tendon. In quadrupeds that want the great toe, the tendon is inserted into the metatarsal bone of the first toe, which it abducts or separates from the rest. This muscle does not exist when there are cannon bones.

The *peroneus longus* in the *monkey* abducts the great toe to the others. The other peroneal muscles of the *monkey*, and of the quadrupeds with claws, resemble the same muscles of the human subject. The *rabbit*, however, is an exception. The *peroneus medius* sends a tendon to the last toe but one. In the cloven-footed order, the *peroneus longus* crosses below

MAMMALIA.

below the joint of the cannon bone to be inserted into the first os cuneiforme. The tendon of the *medius* extends to both the toes, and the *peroneus brevis* does not exit. There is only one peroneal muscle in the *horse*: its tendon joins that of the extensor of the single toe.

The *plantaris* muscle, which terminates upon the os calcis in the human subject, is a stronger muscle in mammalia: it supplies the place of the *flexor brevis digitorum perforatus* in quadrupeds. It is continuous with the *plantar fascia* in the *monkey*, from the dissection of which animal this muscle probably received the name it bears.

In the *wombat*, according to Mr. Brodie, there is a peculiar muscle of the leg. It is situated between the tibia and fibula throughout their whole length. The fibres have their origin from the inner edge of the fibula, and pass obliquely, inward and downward, to be inserted into the opposite surface of the tibia. The operation of this muscle is to bring the fibula forwards, and produce a degree of rotation on the tibia which turns the toes inwards. This muscle is opposed in its action by the one that corresponds to the *biceps*, and which is inserted into the posterior part of the fibula. It brings the toes back into the straight line, but does not turn them outwards.

There are several peculiarities in the arrangement of the flexor muscles of the toes in the *monkey*. The part of the *flexor brevis* that goes to the first toe only is attached to the os calcis. The short flexors of the great and little toes resemble that of the human subject. The *flexor pollicis longus* gives a tendon to the pollex, or great toe, and two perforating tendons to the third and fourth toes. The *flexor longus digitorum* supplies two perforating tendons to the second and fifth toes. The three perforating tendons of the third, fourth, and fifth toes do not come from the bone of the heel, but have their fleshy fibres arising from the *flexor longus digitorum*. The tendons of the long flexors are united together. The *accessory flexor*, or *massa carnea*, has an aponeurotic attachment to the tendon of the *flexor longus pollicis*, and sends a strong tendinous band to the tendon of the *flexor longus digitorum*.

The *flexor longus pollicis*, when there is no great toe, has its tendon incorporated with that of the *flexor longus digitorum*, as in the *dog*, &c.

The *monkey* has a long *abductor* of the great toe; it is situated upon the inner side of the extensor longus pollicis.

The *extensor pollicis* is wanting in those that have not the great toe, such as the *dog* and *rabbit*.

In the *cloven-hoofed* quadrupeds, the inner toe has an *extensor proprius*, which represents the *extensor pollicis*. This is wanting in the *horse*.

The quadrupeds that have cannon bones in place of metatarsals, have the muscle corresponding to the *short extensor of the toes* arising from the cannon bone, and inserted into the tendon of the long extensor.

Plate XI. of the *Anatomy of Mammalia*, exhibits the muscles which move the integuments of the *hedge-hog*. Fig. 1. is the *hedge-hog* in the coiled state, and covered by the orbicular muscle, which is exposed by dissection. Fig. 2. shews the animal in the relaxed state: *aa* is the orbicular muscle contracted, and carried upon the back; *bb*, its marginal part, resembling a sphincter; *cc*, two muscles going from the orbicular muscle to the top of the head; *d*, the muscle of the left side, which is one of another pair that extends from the orbicular to the head; *ee*, the two muscles from the orbicularis to the tail; *f*, part of the muscle which corresponds to the cutaneous colli, seen going to be attached behind the ears; *g*, a portion of the muscle which comes from the middle of the sternum to the orbicularis; *h*, the

cutaneous muscle of the belly; *i*, the portion of the same muscle which passes over the shoulder to be inserted into the humerus. There are other deep-seated muscles which connect the orbicularis with the body and neck, that are concealed by those indicated in this figure.

Plate XI. and fig. 3, is a portion of the trunk of an *elephant*, cut in different directions, in order to expose its structure. A is the horizontal section, in which are shewn the little transverse muscles, *a*, cut cross-ways, and some others cut longitudinally (as indicated by *b*); B is the vertical section made length-ways, by which the nasal canal of the left side at C is divided. The little transverse muscles are, by this section, cut longitudinally at *b*, and transversely at *c*. Some other little analogous muscles are shewn in their length by *d*; and *e* points out the longitudinal muscles of the proboscis, which antagonise these last. D is the vertical section made cross-ways. The little transverse muscles are seen in their length, passing in different directions, with respect to the axis and circumference of the trunk, but always transversely. They are situated within the longitudinal muscles of the trunk, which last are seen divided cross-ways by this section, around the circumference of the trunk, as pointed out by the letters *f, f*: in this section are seen also many vessels and nerves cut cross-ways. Some large nerves, with blood-vessels accompanying them, are shewn running in the direction of the section A, as pointed out by the letter *g*. C, C, are the two nasal canals which run in the interior of the trunk, somewhat nearer the lower surface than the centre.

Brain.—This viscus is formed upon the same plan in *man* and *mammalia*. The chief differences consist in the figure and size of the parts, in relation to each other, to the rest of the nervous system, or to the entire body.

The relation with respect to bulk, between the brain and the whole body, has been generally considered as determining the degree of intelligence possessed by an animal. That the mental character should be indicated by the proportion which the organ of perception bears to the parts which exercise the other functions of life, seems to be almost self-evident; and is conformable to common opinion and observation, with respect to the intellectual powers of different individuals of the human species. Nevertheless it should be observed, that some differences must arise from the age and the degree of fatness of an animal, which cannot be supposed to affect materially the powers of the mind, although they do the weight of the body.

A comparison of the weight of the cerebrum with that of the cerebellum, is another mode employed by anatomists for ascertaining the degree of intellect an animal enjoys, and is more accurate and precise than the preceding. In the inferior classes of animals, the diminution of the cerebrum in proportion to the cerebellum is very striking, and forms a very correct index of the gradations of intellect. But for the purpose of fixing the mental rank of the different tribes of mammalia, it is best to compare the brain with the medulla oblongata, or the nerves that arise in the cranium. This may be done, after the manner of Soemmerring and Ebel, by measuring the diameters of each at their thickest part. This last mode seems to shew, with tolerable accuracy, the intellectual endowment of the different genera of mammalia, except in the *whale* tribe, which have the brain so very broad in proportion to its length. The same rule also serves to correct the conclusions that would be drawn from comparing the weight of the brain with that of the whole body, in some of the *monkey* kind, and the very small quadrupeds, which have as large a brain in proportion to their body as man.

MAMMALIA.

In judging of the capacities of animals, we should carefully distinguish between the operations of intellect and of instinct. These are often mistaken for each other in animals, and, we believe, are more frequently confounded in the workings of the human mind than people in general are aware of. The brain is the seat of reflection, and of *ideal* knowledge: the nerves and organs of sense are but its agents; they are incapable of performing any intellectual operation of themselves. The perfection of the organs of sensation determines, however, in a great degree, the *instinctive* faculties of animals, independently of the influence of the brain. Indeed the intellectual and instinctive powers are found, like the organs upon which they depend, to exist in an inverse ratio to each other. Man, who has the highest mental character, has the brain largest, and the nerves smallest in relation to each other; and in the inferior classes of animals, whose actions are almost entirely governed by instinct, the nerves are uncommonly large, and the brain extremely small; and even in some genera hardly distinguishable.

To illustrate this subject, the following tables have been extracted from Cuvier's "Comparative Anatomy," vol. ii.

TABLE I. exhibits the proportion of the size of the brain to that of the whole body.

Man,	according as he is young or old	$\frac{1}{25}$	$\frac{1}{25}$	$\frac{1}{30}$	$\frac{1}{35}$
Long-armed ape, or gibbon					$\frac{1}{15}$
Orange monkey (<i>simia sciurea</i>)					$\frac{1}{15}$
Capucin monkey (<i>simia capucina</i>)					$\frac{1}{15}$
Striated monkey (<i>simia jacchus</i>)					$\frac{1}{15}$
Four-fingered monkey (<i>simia paniscus</i>)					$\frac{1}{15}$
Malbrouck (<i>simia faunus</i>), young					$\frac{1}{15}$
The green and red monkeys					$\frac{1}{15}$
Varied monkey (<i>simia mona</i>)					$\frac{1}{15}$
White-eye-lid monkey (<i>simia ethiops</i>)					$\frac{1}{15}$
Hare-lipped monkey, or macaque					$\frac{1}{15}$
Barbary ape					$\frac{1}{15}$
Great baboon					$\frac{1}{15}$

LEMURS.

Ring-tailed maucauco (<i>lemur catta</i>), young					$\frac{1}{15}$
Vari (<i>lemur macaco</i>)					$\frac{1}{15}$

CHEIROPTERA.

Great bat (<i>vespertilio noctula</i>)					$\frac{1}{35}$

The

MAMMALIA.

The brain of the *monkey* resembles most closely that of the human subject; but is nevertheless distinguished by certain differences, which form, as it were, the first steps in the gradations of structure in this organ.

The superior surface of the *hemispheres* is somewhat flatter in the *monkey* than in man; but in *quadrupeds* it is considerably flatter. In some of them also, as most of the *digitated*, the anterior part of the cerebrum is much narrower than the posterior. The *hoofed* quadrupeds generally have the brain nearly oval in its circumference, as it is in man and the *monkey*.

In quadrupeds the *middle lobes* of the cerebrum are flattened upon the inferior surface, and the posterior lobes do not exist; consequently the cerebellum is not concealed by the cerebrum, as in man and the *monkey*.

The brain of the *porpoise*, *dolphin*, *grampus*, and most probably others of the *whale* kind, has a figure different from that of any other animal: it is rounded at every part. Its greatest diameter is across, yet it covers the superior part of the cerebellum: it has numerous and deep convolutions.

In mammalia, even in the *monkey*, the middle lobes of the cerebellum are larger, in proportion to the lateral ones, than they are in man. These lobes are of the same size of the others in the *saltigrada*.

The division of the external surface of the brain into *convolutions* takes place to a less extent in mammalia than in man. There are few convolutions in the *monkey* tribe, particularly in those with prehensile tails, which have the posterior lobes nearly smooth. The *jacko* and *Barbary ape* are exceptions, and have the posterior lobe separated from the others by a distinct transverse fissure.

In the *digitigrada* and *plantigrada* the furrows upon the surface of the brain are tolerably numerous, and are arranged in a regular order.

The *saltigrada* have no convolutions, properly speaking, but very faint grooves; their brain is almost smooth upon the surface. There are deep convolutions on the brain of the *hoofed* quadrupeds, especially the *cloven* and *solid-footed* tribes.

The lower surface of the brain of mammalia is less unequal; the different prominences not projecting so much as in man.

The *olfactory* nerves of quadrupeds are of an enormous size, and contain a cavity which communicates with the lateral ventricles: they are composed of cineritious substance externally, and medullary internally. They were described by the early anatomists under the names of *caruncule mammillares*, or *processus mammillares*. They are found of the greatest size in the large herbivorous quadrupeds.

There are no olfactory nerves in the *cetaceous* animals.

Except the peculiarities we have just mentioned, the origin of the nerves is the same in man and mammalia.

The *lateral ventricles* have less extent in all mammalia, except the *monkey*, than in man. That portion of their cavity which is called the *posterior horn*, or *digital cavity*, is only found in the *monkey*, in which the posterior lobes exist.

The *tubercula quadrigemina* become larger, in proportion as the animals are removed from man. They are of the greatest size in the *saltigrada*, *bifulca*, and *solipeda*. There is a very singular proportion observed between the superior and inferior of these tubercles. In all the *herbivorous* tribes of quadrupeds, the *nates*, as they have been called, exceed very much in size the *testes*; and in the carnivorous quadrupeds, whether *digitigrade* or *plantigrade*, the inferior tubercles or *testes* are larger than the *nates*; from which it might be supposed that the relative magnitude of these parts

indicate the disposition of the animal. Cuvier states, that the *testes* are three times the size of the *nates* in the *dolphin*.

But few observations have been made upon the comparative structure of the *pineal gland*. The gritty or earthy substance of this body has been discovered in the *fallow deer* (*cervus dama*) by Soemmerring; and in the *goat* by Malacarne. It is not known in what number of quadrupeds the earthy matter exists in the pineal gland: it may be presumed, from its being found in the species above mentioned, which are less allied to the human subject in general structure than many others of this class, that the sandy matter would be met with generally in the pineal gland of mammalia.

The *corpora candecantia* are small in the carnivorous quadrupeds: there is but one large eminence of this kind in the herbivorous tribes.

The other eminences and cavities of the brain of mammalia exhibit no peculiarities worthy of notice.

The *tentorium cerebelli*, in many mammalia, is sustained by a thin plate of bone, which projects from the inner surface of the cranium in one or three pieces.

In some instances the tentorium is an uniform bony partition, which leaves a quadrangular opening into the lower part of the cranium. This is the case in most species of the *cat* and *bear* genera; in the *martin* and in the *coati* (*fimia paniscus*).

The *falx*, which divides the hemispheres of the cerebrum, is also sustained upon a bony plate in the *ornithorhynchus*. Blumenbach states, that something of the same kind exists in the skull of the *porpoise*; but the specimen to which he refers, appears to have been an irregular formation of the bones of the cranium.

The *membranes* of the brain do not exhibit any other peculiarities of much importance in mammalia.

The *blood-vessels* of the brain have been described already under the heads of *Arteries* and *Veins* in this article.

In *Plate XII.* of the *Anatomy of Mammalia*, *fig. 1.* is a lateral view of the external appearance of the brain in the *rabbit*. The anterior part of the cerebrum is seen to be smaller than the posterior. The middle lobes are flattened upon their inferior surface; and the posterior lobes are wanting: *a a* shew the cerebrum; *b*, the cerebellum; *c*, the medulla oblongata. *Fig. 2.* is a view of the under surface of the anterior part of the cerebrum of the *sheep*: *a, a*, the olfactory nerves; one of which is laid open to expose its cavity, which is traced to the lateral ventricle, by cutting through the substance of the cerebrum. *Fig. 3.* is a transverse section of the brain of the *monkey*: *a a*, the corpora striata; *b b*, the thalami nervorum opticorum; *c c*, the cavities of the lateral ventricles laid open; *d d*, the digital cavities; *e e*, the *nates*; *f f*, the *testes*; *g g*, the pineal gland; *h, h*, the cut surfaces of the hemispheres. *Fig. 4.* is a view of the tubercula quadrigemina in the *sheep*: *a a*, the *nates*; *b b*, the *testes*; *c c*, the surrounding portion of the brain. *Fig. 5.* is a similar view of those parts in the brain of the *dog*, which are indicated by corresponding letters.

Nerves.—There is no part of the anatomy of mammalia in which there is so close a resemblance to the human, as in the distribution of the nerves. Where differences do occur, they are in general plainly referrible to the difference in the figure of the neighbouring parts, and not to any physiological reason.

The *first pair of nerves*, or the *olfactory*, afford a striking exception to the foregoing observation. In all mammalia which possess them, except the *monkey* kind, they are large, hollow processes of the anterior lobes of the cerebrum, the

cavities

MAMMALIA.

cavities of which communicate with the lateral ventricles of the brain, as already described. This peculiarity of structure, however, does not appear to produce much effect upon them after they have passed through the ethmoid bone into the nasal cavity. The only difference to be remarked between the branches of the olfactory nerves of quadrupeds and those of man, is, that they are stronger, and more easily demonstrated in the former.

The *second pair of nerves, or optic*, have precisely the same structure in mammalia and man before their entrance into the globe of the eye. The medullary tubes of which they are composed, are more plainly shewn in the larger quadrupeds.

The *third, fourth, and sixth pair of nerves*, exhibit no peculiarities.

The *fifth pair of nerves* shews some difference in its ramification, and the ganglia it forms, although its distribution is, as nearly as may be, the same in mammalia and man. Cuvier has given some account of the three principal branches of the fifth pair of nerves, taken from dissections of the *dog, rabbit, sheep, and calf*.

According to Cuvier's description, the first, or *ophthalmic* branch of the fifth pair, is divided within the cranium, but does not form its three branches until it arrives in the orbit.

The first, which is analogous to the *nasal* branch of the ophthalmic, is the largest. It is divided into five or six small nerves. Some of these pass through the vault of the orbit to the frontal sinuses: others, which are larger, enter the nasal cavity by the internal orbital foramen. They ascend in an osseous canal, and pass into the cranium by the large foramina of the cribriform bone, and pass down again through the ethmoidal foramina, to be distributed, as in man, to the pituitary membrane of the nose. These branches are very plain and easily traced in the *cloven-footed* quadrupeds: one of them seems to have been mistaken by Cuvier for a branch of the olfactory in the *sheep*. One or two of the branches into which the nasal divides, go to the levator palpebræ superioris. One of these twigs assists in forming the *lenticular ganglion*, which in the *dog* gives off two *ciliary* nerves that divide before they enter the eye, and in the *calf* it sends off four ciliary nerves. Finally, the nasal sends filaments to the obliquus inferior muscle, and the glandula Harderi.

The *second, or frontal* branch of the *ophthalmic*, is situated superiorly under the roof of the orbit. It divides into two nerves; one is external, and furnishes two filaments to the rectus superior and the levator palpebræ; the other is internal, and supplies the internal straight muscle of the eye, and gives off the frontal branch which passes through the superciliary notch, to be distributed to the integuments of the forehead.

The *third, or lacrymal* branch of the *ophthalmic*, furnishes a great number of filaments that are expended upon the lacrymal gland.

The *second* branch of the *fifth pair*, or the *superior maxillary* nerve, when it arrives on the outside of the cavity of the cranium, becomes considerably enlarged. Its fibres seem to cross each other in such a manner, that the two branches which it soon after forms appear to be produced by opposite filaments: thus, the posterior, or *sub-maxillary* branch, seems to be composed of the anterior filaments, and the anterior or supra-maxillary branch of the posterior fibres. This disposition is very remarkable in the *dog*, but less so in the *calf*.

The supra-maxillary branch proceeds almost horizontally

from behind forwards. Having reached the anterior and inferior parts of the temporal fossa, it divides into a great number of fasciculi: one bundle, which consists of four or five filaments, proceeds towards the sphenopalatine foramen. This fasciculus then divides into two; one branch is sent into the nasal cavity, and furnishes a considerable nerve, which is spread out upon the fleshy substance of the palate. Sometimes, as in the *calf*, this branch separates from the trunk, even before it enters the sphenopalatine hole.

The other branch of the superior maxillary nerve, which enters by the sphenopalatine hole, passes into the body of the superior maxillary bone, detaches filaments to all the teeth, and goes out by the sub-orbital foramen, where it expands into a great number of branches, which supply the muscles and integuments of the face, and anastomose with the branches of the facial nerve. The *sub-orbital nerve* and its branches are of a prodigious size in all mammalia with whiskers; in these animals its anastomoses are more intricate than usual, and from the net-work under the skin about the lips, the bulb of each whisker receives one or more large nerves.

There are some other filaments given off from the superior maxillary nerve. The first is a small one, which, after anastomosing with a ganglion, passes into the substance of the temporal muscle, to which it gives branches. It afterwards perforates the orbit, and from thence goes into the nose. Another more remarkable filament arises from the sphenopalatine branch; it forms a ganglion, which is joined by the preceding nerve, as already mentioned, and several other twigs. A flat nerve proceeds from this ganglion, which appears to be the continuation of the nerve that formed it, although larger. It passes between the palatine and the convexity of the pterygoid process, in the substance of the bone: amongst other branches it sends one down to the floor of the nostrils.

The *third, or inferior maxillary* branch of the *fifth pair* of nerves, produces, almost immediately after its separation, a pretty large branch, which is distributed to the parotid and maxillary glands. It afterwards divides into two other branches; one which is internal, and is lost in small filaments in the muscles, and even in the substance of the tongue; the other is external, and sends a number of branches to the pterygoid muscles, and those of the cheeks and lips, on their way to the skin of the face on which they are lost, anastomosing with the other facial nerves. The continuation of the superior maxillary nerve passes, as usual, into the canal of the lower jaw, supplies the teeth, and emerging at the foramen mentale, spreads in branches upon the soft parts in the neighbourhood.

In the *calf*, the inferior maxillary nerve, soon after leaving the cranium, divides into four branches.

The most posterior of these branches goes backwards, and below the condyle of the jaw, where it forms two branches; one is slender, and enters the parotid gland, to which it gives filaments, which anastomose with those of the facial nerve; the other takes the circuit of the jaw, and advances in the front of the mouth; it unites, as it passes along the cheek, with the middle branch of the facial nerve, from which it previously receives several anastomosing branches.

The next branch of the four is very long, slender, and follows the ramus of the jaw to be expended upon the buccinator muscle and the glands.

The third branch passes into the dental canal, and supplies the teeth as usual.

Lastly,

MAMMALIA.

Lastly, the fourth branch is the lingual: it is strong and flat, and terminates in radiated filaments.

The facial nerve, commonly called the *portio dura* of the seventh pair, arises in the calf, according to Cuvier, by two roots; the one is really the portio dura: the other appears to proceed from a considerable ganglion of the posterior part of the *par vagum*, which is situated in a particular depression of the inferior surface of the bone of the tympanum: this root also appears to unite with the great sympathetic nerve, which has almost the firmness of cartilage. Two or three short filaments concur in the formation of this root. It afterwards becomes thicker, and passes into the fissura Glaseri to meet the other roots of the facial nerve, to which it transmits a filament, and continues to proceed outwards before and below the ear.

The magnitude of the branches of the facial nerves varies in mammalia, but with respect to number, they scarcely differ from those of the human subject. In those quadrupeds that have large ears, the branch of the facial nerve, which unites with the first cervical pair, is of much greater size than ordinary. In the carnivorous kinds, also, the nerves going to the temporal muscle are particularly large, and in all mammalia with whiskers, the branches that anastomose with the facial nerves of the fifth pair have a considerable size.

There is nothing peculiar to be observed with respect to the *portio mollis* of the seventh pair, or the true auditory nerves.

The species that Cuvier had dissected for the *par vagum*, or *pneumo-gastric* nerve, were the calf, dog, racoon, hog, and the porcupine, in all of which, its distribution and ramifications bore the greatest resemblance to the same nerve in the human body. The connection it has with the facial nerve in the calf already mentioned, was the chief peculiarity observed.

The *glossopharyngeal*, and the *hypo-glossal* nerves, exhibit no deviation from their disposition in the human body, as far as they have been examined.

The *hypo-glossus* was found by Cuvier to have a blueish colour in the calf, until it arrives on the inside of the ramus of the lower jaw.

The *sub-occipital* and the *cervical* nerves also appear to be formed exactly as in man. They are of course in some quadrupeds larger in proportion than in others, on account of the size of the muscles on the neck. In the *three-toed sloth*, there are probably nine cervical nerves corresponding to the number of vertebræ in that animal.

The *phrenic* nerves differ in no respect from those of man.

The *dorsal* and *lumbar* nerves vary only in regard to their numbers, which may be reckoned by the vertebræ. The nerves of the *pelvis* also exhibit no peculiarity in mammalia:

The nerves which supply the tail are of some consequence in this class, and do not exist in the human subject. The following description has been given of them in the *rabbit* by Cuvier.

The first pair of caudal nerves comes out between the last piece of the sacrum and the first vertebra of the tail, and proceeds by the ischiatic notch. It divides into two branches, one of which is united to the schiatic nerve, and the other continues to advance between the pelvis and the tail, until it enters a gland situated under the sixth pair of caudal nerves, where this branch terminates: but in its way thither it forms several anastomoses with the other caudal nerves, and gives off branches, by which there is a remarkable plexus formed, which Cuvier calls the *caudal*.

The first branch sent off by this nerve is distributed among the gluteal muscles. The nerve is afterwards joined on the inner side by a small filament, that seems to be derived from the second pair of caudal nerves, and on the outer side by three or four filaments, which make a plexus, from whence several branches go to the muscles; one, which is very considerable, and easily traced, is sent to the penis. Afterwards the third, fourth, and fifth pair of caudal nerves send filaments to the inner side of the branch of the first pair: then five or six branches are given off from the external side of the muscles of the penis, and those which arise from the ischium. Finally, the trunk of the first caudal pair terminates in the gland, as above-mentioned.

The *great sympathetic*, or *intercostal* nerve, has been described by Cuvier from dissections of the *wolf*, *racoon*, *porcupine*, *sheep*, and *calf*. He found it to form a very remarkable anastomosis with the fifth and sixth pair of nerves. On entering the cranium through the foramen lacerum, the intercostal is distinct from the *par vagum*, and adheres very closely to the periosteum of the temporal bone. If the cord of the nerve be stretched, it is seen to be divided into six or seven filaments, that form a close network. A few lines farther, these filaments approach each other, and become consolidated into a ganglion, which, from its great firmness, appears like cartilage. Many filaments depart from this ganglion: some are short, and proceed to the nerve of the fifth pair: others are long, small, and are interwoven with the blood-vessels, so as to form a reddish-coloured plexus, which was considered by Willis as a little *rete mirabile*. The communication with the sixth pair is by means of this plexus, which surrounds the nerve on every side, and is hardly to be separated from it. There is not any remarkable anastomosis observed in the *calf* and *ram*.

The great intercostal, while passing through the foramen lacerum, detaches a filament to the cavity of the tympanum. At the same place also it is united with the eighth pair of nerves.

The *superior cervical ganglion* is formed some lines from the cranium. It has a reddish colour, and an elongated oval figure. It forms the same communication with the neighbouring nerves as in man.

In front of the last cervical vertebra the intercostal nerve forms a curve from within outwards, towards the first rib, on the head of which it joins the first thoracic ganglion. Several filaments from this curve go along the mediastinum to the pericardium: others form a plexus around the subclavian artery.

The *first thoracic ganglion* is a femilunar figure. Some filaments go off from one of its edges; the uppermost of which is sent to the vertebral artery, around which it forms a plexus, and appears to accompany the vessel into the cranium. The other filaments unite with the last cervical, and with the two first dorsal pair of nerves.

The concave edge of the ganglion detaches two or three filaments, which descend obliquely to the root of the pulmonary arteries, where they unite with the *par vagum*, to form the *pulmonary* and *inferior cardiac plexuses*.

The intercostal, in its passage through the thorax, produces a ganglion upon the head of each rib, which is joined by a filament from each of the dorsal nerves.

The intercostal, on entering the abdomen, forms a single cord, which is the *splanchnic nerve*. It passes into the middle, under the stomach, where it frequently separates into two cords, which are afterwards joined together again. From this sort of nervous ring, there arises either a principal trunk, or four or five filaments, which, uniting together near the cæliac artery, form a ganglion, that is frequently of a semi-

MAMMALIA.

lunar figure. The filaments that produce the *stomachic*, *splenic*, and *hepatic plexuses*, arise from the semilunar ganglion, and correspond to the *solar plexus*. There are also filaments detached to form the *renal plexus*.

The intercostal, as it proceeds along the lateral parts of the bodies of the vertebrae, gives origin to *ganglia* of an elongated quadrangular figure: one of the superior angles of these receives the continued trunk of the nerve; the other the lumbar pair. The internal inferior angle sends a branch to the aorta, to concur in the formation of plexuses, which encompass each of the branches of that vessel. The external inferior angle furnishes the continuation of the trunk.

Except the variations above-mentioned, there does not appear to be any material difference between the intercostal or great sympathetic nerve in man and animals.

Scarcely any peculiarity is to be perceived in the distribution of the nerves of the extremities in mammalia. The *articular nerve* is exclusively formed in the *rabbit* by the fifth cervical pair of nerves; only one of its filaments is derived from the axillary plexus.

The *thoracic nerves* are furnished by the axillary plexus.

The *median nerve*, about the middle of its course, sends off a branch, which is analogous to the *external cutaneous nerve*.

The *ulnar nerve* also, about the middle of the arm, gives off a branch, that appears to take the place of the *internal cutaneous nerve*: it supplies the extensor muscles of the elbow and the skin.

Both the origin and distribution of the nerves of the posterior extremity appear to correspond with what has been described in man.

Organs of Touch.—The general surface of the body in mammalia is better calculated for receiving external impressions than it is in any other animals, except those that have naked and soft skins, such as certain reptiles, and some of the inferior classes. The skin of mammalia is well supplied with nerves; the cuticle is thin, and the hairs, having their roots buried in the skin, rather facilitate than impede the sensation of touch.

The *cuticle* has the same structure in man and mammalia. It is most delicate in the smaller quadrupeds, and in those that have their body well defended by other coverings, as very thick hair or spines. The cuticle is particularly thin in the *porcupine*.

It is dry, and consists evidently of scales, on the tail of the *beaver*, *rat*, *ondatra*, &c. and upon the surface of the bodies of the *porcupine* and *armadillo*.

In the *large many-hoofed quadrupeds* the cuticle is thick, and is covered with small plates, that separate from it like scales. It sinks into the furrows of the true skin. On the soles of their feet it is very remarkably formed. It appears externally to be divided by deep impressions, nearly circular, with six or eight surfaces, some more regular, others less so, each of which contains an infinite number of small polygons, that are very irregular. These polygons, both the large and small, correspond to furrows in the true skin, into which internal projections of the cuticle are inserted.

The cuticle of the *cetacea* is not thick in proportion to the other parts of the skin. It is free from folds or wrinkles; the surface of these animals being smooth, to facilitate their progress through the water. It is also besmeared with oil, which not only is of use in swimming, but prevents the maceration of the cuticle in the water.

The *colouring matter* of the *skin*, or *rete mucosum*, as it is commonly, though improperly, called, is usually thin, and of a light colour in those parts of the bodies of quadrupeds which are covered by hair: on particular parts, however,

and in certain animals, it is various in its colour. It is generally black upon the uncovered parts of the skin, as the snouts of quadrupeds, the hands of *monkeys*, &c. It has but rarely very vivid colour, as in the other classes of animals. The *monkey* kind shew examples in which the cheeks have a painted white or blue colour, and the nose or ischiatic callosities are red, violet, or carmine.

The pigment of the skin of the *cetacea* vastly exceeds in thickness that of all other animals. It is about the tenth of an inch thick in the *porpoise*, and in the larger species of the *whale* tribe it is proportionably thicker. It appears like a solid substance, which divides very readily after maceration into layers, and also in the vertical direction into fibres, like the pile of velvet. This laminated and fibrous structure is only the particular arrangement of the substances of the pigment, and not a texture composed of different parts, for the whole is soluble, or rather miscible, in water after maceration. The *rete mucosum* of the *cetacea* is black upon the superior surface of the body, but is a silvery white on the belly.

The pigment of the skin is found within the cavities of the mouth and nose in many quadrupeds, in which places it has a dark colour.

The *cutis*, or *true skin*, varies of course very much in thickness in different animals of this class: as a general observation, we may state that the skin is thick in proportion to its nakedness, and its exposure to external friction or pressure. It is therefore most strong in *many-hoofed quadrupeds*, to whom these circumstances belong, as well as great bulk of the animals themselves. The skin is always thickest upon the back of the body and outside of the limbs. The thickness of the skin may be increased to a very extraordinary degree by artificial pressure, as is seen in the *boar pigs* that are used for making *brawn*. In these animals, the skin upon the shoulders is sometimes above an inch thick.

The skin is peculiarly tough in those animals that burrow in the ground. In the *mole*, although it is thin, it is so tough, that it is difficult to cut it with a pair of scissors.

The skin of *cetaceous mammalia* is peculiar in its structure. The surface next the *rete mucosum* is smooth, and when examined under water, floats like a villous texture. We could not readily detect any distinct villi upon the skin of the *porpoise*, or *grampus*, they are so fine and so close to each other; but Hunter has described them as being very plain in *whales*. It is scarcely possible to calculate the thickness of the skin of *cetacea*, as it is gradually lost in the cellular texture which contains the oil, but it appears to be peculiarly thin, according to the size of the animals, unless we consider the cellular substance that is filled with the oil as making a part of the skin, which appears really to be the case. Every part of the skin of the *whale* tribe is penetrated by the oil.

The skin of *cetacea* appears to be less sensible of external impressions than that of any other species of mammalia. The smoothness, and stretched state of the cuticle; the thickness of the *rete mucosum*; the absence of those small eminences of the cutis called papillæ, which are peculiarly endowed with blood-vessels and nerves, and the interposition of so great a quantity of oil in the interstices of the skin and cellular substance, all contribute to obscure the impressions of foreign bodies.

Certain parts in the other mammalia, from their situation, figure, and intimate structure of the skin covering them, are fitted to receive peculiar impressions, and are, properly speaking, the *organs of touch*. The most delicate instruments of this kind are, the *hands* of the *quadrumanous mammalia*; the *lips* and *snouts* of many quadrupeds; the *prebensible tails* of *monkeys*, *opossums*, *ant-eaters*, *porcupines*, &c.

The

MAMMALIA.

The under surfaces of the hands and feet of *monkeys* are organized like those of the human subject, but have not the nervous papillæ so eminent as they are in the human hand.

The feet of *digitated* quadrupeds also are capable in a degree of the sensation of touch, particularly the under surface of the front toes in the *raccoon*.

The lips of many quadrupeds form a very delicate sense of touch. They are largely supplied with nerves and blood-vessels, and the papillæ of the skin are very eminent. The superior lip of the *rhinoceros* forms a process which is moveable in various directions, and is used by the animal as a prehensile member.

The snouts of the *hog*, *mole*, *desman*, and *tapir*, are extremely well constructed for feeling with; being very moveable by the muscles already described, highly elastic in themselves, and their extremity having, like a lip, a papillated surface, which is richly endowed with nerves and vessels. But the proboscis of the *elephant*, as being capable of embracing bodies entirely, in addition to the great sensibility of its extremity, constitutes, perhaps, the most perfect organ of touch with which we are acquainted.

The inferior surface (which is the one applied to bodies) of the prehensile tails of mammalia, is divested of hair, and the skin is papillated as upon the end of snouts, &c. Cuvier states that he found the papillæ very distinctly upon the under surface of the tail in the *Cayenne opossum*.

In some cases, foreign impressions are conveyed by the medium of insensible parts. This may be observed with respect to whiskers, nails, hoofs, and horns, which are intimately connected with parts so extremely sensible, that the slightest impression upon them in an uncovered state would be highly painful. The vascular and sensible substances, which we find clothed by these horny integuments, are better calculated for producing the perception of the mere existence of solid or resisting bodies, than any of the other organs of touch; but are incapable of furnishing any idea of the figure of foreign substances. The insensible integuments and appendages of different animals are described under their proper heads in this dictionary; and there is also a plate allotted to the illustration of their structure and mode of growth.

In the *ornithorhynchus paradoxus* the external branches of the fifth pair of nerves are very large, and are distributed on the integuments of the bill of this curious animal, precisely in the same manner as in the broad bills of the *anserine birds*, and thus produce a very nice organ of touch. See *Anatomy of Birds*, in this dictionary.

The peculiar muscles, which move the skin and the organs of touch in mammalia, are already described, along with the other muscles of the body.

The integuments of the wing of the *bats* are so thin, that they are transparent, and permit one to see the distribution of the nerves, which form between the membranes of the wing a beautiful plexus. A contemplation of this structure should have taught Spallanzani and Jurin that *bats*, when flying, must be adverted of the existence of any resisting bodies, on approaching them, by the difference in the impulse of the air upon the concave surface of the wing; and have rendered the cruel experiments of these physiologists upon *bats*, in order to discover their sixth sense, unnecessary. From the first time we dissected this animal, we were convinced that it directed itself altogether by means of the sensibility of the wing. The mode of flying observable in *bats* appears to be perfectly consistent with this notion. They usually proceed as if they had no perception of objects, until they arrive within a near distance of them, when they either suddenly turn aside, or directly round, as if to avoid being dashed against them. Blind men are known to direct them-

selves by means of the feeling of resistance in the air, on approaching walls or houses, &c.; and even a person, whose sense of feeling has never been practised to discriminate so nicely, can discern the walls in a dark room, on approaching them very nearly, without touching them with any part of the body.

Organ of Taste.—The sense of taste is generally supposed to reside altogether in the tongue; but some substances excite particular tastes, in passing over the inside of the lips and the fauces. The irregular denticulated folds which the lips form in the *clowen-footed* quadrupeds, the *dog*, &c. seem particularly well calculated for receiving the impressions of sapid bodies.

Blumenbach mentions a man who was born without a tongue, yet could discern the taste of sapid substances, when passing over his palate.

The muscular structure and mechanism of the tongue have already been described, under the heads of the *organs of mastication* and the *organs of motion*: it, therefore, only remains to consider some peculiarities in the form of this member, and the organization of its integuments, which alone possess the sense of tasting.

The tongue in the *monkey* kind has not quite the same figure as in man; it is longer and thinner: even in the *ourang-outang* it is three times as long as it is broad. In the *digitigrade* quadrupeds it is long, thin, and flexible: it is so also in the *clowen* and *solid-hoofed tribes*. The *hog* has a short tongue, with the edge divided into a number of processes like fringe. The tongue of the *seal* is thick and short, and has on each side of the point a ragged notch, or deficiency, having the appearance of a piece being bitten off. The singular long-shaped tongue of the *ant-eaters* has been already mentioned, and the mechanism on which it depends described. The tongue of the *cetacea* is short, flat, and smooth, and bears considerable resemblance to that organ in fishes.

The three kinds of papillæ observed in the integuments of the human tongue, *viz.* the *conical*, *fungiform*, and *incupped*, exist in mammalia. Their varieties in different genera relate principally to the form and covering of the conical, and the number of the other sorts of papillæ.

In the *prehensile-tailed monkeys* the conic papillæ are but small: they have but three incupped papillæ, which are arranged like the three points of a triangle. The *mandril* (*simia maimon*), and the *simia cynocephalus*, have also three incupped papillæ in the same position. The *simia cynomolgus* has four incupped papillæ arranged in the form of a portion of a circle. The *Chinese monkey* has seven, making an elongated triangle, with two before it in a line. Several other *monkeys* have been observed to have fewer incupped papillæ than the human subject.

The tongue of the *common bats* has the conical papillæ very fine and long, somewhat like hairs, particularly on the back part. The inside of the mouth also has some of these papillæ upon it. In the *ternate bat* the conic papillæ are horny, and at the extremity of the tongue are divided into several points.

The whole of the *cat* genus (*felis*) have the conical papillæ, that are on the middle of the tongue, clothed with horny integuments. These are little hooks or claws, sharp pointed, and when on the tongue, are inflected backwards; so that when any of the larger animals of this genus employ the tongue in licking the human hand, they tear off the skin. When the papillæ of the tongue are covered by a horny substance, they seem to be insensible to the impressions of sapid bodies; we therefore find, in the *cat* kind, soft round papillæ interposed between the horny ones, upon the middle

MAMMALIA.

of the tongue. These two kinds of papillæ are placed alternately in a quincunx order, so that there is an equal number of both upon the tongue. There are soft, conical, fungiform papillæ upon the edges of the tongue. Upon the back part of the organ the horny papillæ disappear; and there are some small incupped papillæ arranged in two lines, that approach posteriorly. In the *common cat*, Cuvier states that there are on the sides of the back part of the tongue some fungiform papillæ, which are pendent from long pedicles. The tongue of the *civet* resembles that of the *cat* genus.

In the other *digitigrade* and *plantigrade* quadrupeds the tongue is soft and flexible. The only variations are with respect to the number and position of the incupped papillæ, which are scarcely worth detailing.

The tongue of the *opossums* has the anterior and middle part covered with horny scales inflected backwards, which terminate in wedge-shaped or rounded edges: the point of the tongue is fringed: there are but three incupped papillæ. The tongue is, however, soft in the *phalangers*.

The *porcupine* has the upper surface of the tongue like that of the other *saltigrada*; but upon its sides, and at the end, there are some large scales terminating in two or three points of a wedge-shape. There are but two large incupped papillæ. The other animals of this order have also fewer incupped papillæ than man.

The conical papillæ are so minute, as to be scarcely discernible in the *armadillos* and *Cape ant-eater* (*orycteropus*). These animals have the tongue long, narrow, and very smooth: they have also only two or three incupped papillæ.

In the *American ant-eaters* the tongue is without papillæ, and is therefore not an organ of taste. Indeed in all the *edentata* or *insectivorous* quadrupeds, this member seems to be merely a mechanical instrument for taking and swallowing their prey.

The *stoats* have the conic and fungiform papillæ but little developed, and only two papillæ in cups.

The *many-hoofed quadrupeds* have all the papillæ of the tongue small.

The *cloven-footed* order of mammalia have the conic papillæ upon about the anterior half of the tongue, terminating in flexible horny filaments. They are bent backwards, and end in a point. In the smaller *bifulca* the horny coverings of the papillæ are so small, as to be seen with difficulty; but in the larger species, particularly the *camel*, these filaments are long, and give the touch of the tongue something of the feeling of velvet. The back part of the tongue, in the *bifulca*, is covered by thick tuberculated papillæ, which sometimes are cone-shaped, and at others semi-spherical, and which become smaller towards the sides. The incupped papillæ are numerous, and situated on the sides of the back of the tongue. They are not easily distinguished from the fungiform, except in the *camel*, in which they are very large, and concave on their surface.

The conical papillæ are very small and compact in the *horse*, and the fungiform papillæ are confined to the sides of the tongue. There are but three of the incupped papillæ, and the surface of these is irregularly tuberculated.

There do not appear to be any conical papillæ on the tongue of *cetacea*. Cuvier states that they cannot be observed, even with a glass, on the tongue of the *dolphin* and *porpoise*. There are on it some eminences like pimples, and at the base of the tongue there are four fissures: the edges of the extremity of the tongue form small shreds. Hunter compares the tongue of the large *whales* to a feather bed.

In *Plate XIII.* of the *Anatomy of Mammalia*, *fig. 1* is a view of the tongue of the *cat*: *a*, the part covered with the spiculated papillæ; *b*, the pendent fungiform papillæ; *c, c*, the two rows of incupped papillæ. *Fig. 2* is one of the horny hooks removed from the tongue of the *leopard*, and magnified to about four times the natural size. *Fig. 3* shews the tongue of the *porpoise*: *a*, the point of the tongue terminating in shreddy processes; *b, b, b*, the pimple-like eminences upon the upper surface of the tongue.

Organs of Smelling.—The apparatus for receiving the impressions of odorous effluvia is much more complicated in mammalia generally than in man, which is consistent with the great excellence of the sense of smelling in many of the former.

The parts of the *ethmoid* bone, which enter into the composition of the orbits and the parietes of the cranium, have been described in their proper places. The foramina of the cribriform plate, through which the branches of the olfactory nerves pass, appear to be numerous in proportion to the perfection of the sense of smelling. They are less numerous in the *monkey* than the human subject.

In quadrupeds these foramina are of different sizes, and collected into groups. In some species of different tribes, as the *sheep*, *hog*, *ant-eater*, &c. there is a row of larger holes on each side of the cribriform plate of the ethmoid bone. The *saltigrade quadrupeds* have the fewest foramina in the cribriform lamella, and the *digitigrade* the greatest number of them.

The cells of the *ethmoid bone*, as they are generally found in mammalia, are well described by Cuvier. He says, it is necessary to imagine a great number of hollow pedicles, all connected to the cribriform bone. They extend forwards and outwards; and, in proportion as they advance, those which are nearest unite. Vesicles arise from them, which increase in size in proportion as they become less numerous: they are all hollow, and there are an infinite number of conduits or ways between them, all of which communicate with each other. The ethmoidal cells are most numerous in the *carnivorous quadrupeds*, which have the finest sense of smell. In the *saltigrade* order there are very few of these cells. Some genera of this tribe, as for instance the *bare*, and the *quadrumanous mammalia*, have irregular cells like those of the human subject.

The ethmoidal cells are distinct from the superior turbinated bone in many mammalia. They are sometimes separated from the rest of the nasal cavity by a particular septum. This is especially to be observed in the *hog*, where it is produced by a plate of the palatine bones inferiorly, and anteriorly by a process of the maxillary bones. It extends to the septum nasi, and leaves only a narrow passage above it. In the *carnivorous* tribe and the *horse* the projection of the maxillary bones is less considerable; but it is sufficient to separate the ethmoidal cells, which are contained in a depression behind it. In the *saltigrade* and *cloven-hoofed quadrupeds* this depression is little marked.

The superior turbinated bone is formed by one of the ethmoidal cells in the *hoofed quadrupeds*. This cell is larger and much longer than the rest, and extends as far as the inferior turbinated bone which it covers.

The inferior turbinated bones are much more complicated in mammalia than in man.

Cuvier says, in the *monkeys* of the old continent, they are formed as in the human subject, but in the *American monkeys* these bones are made nearly as in the *many-hoofed* and *cloven-footed quadrupeds*.

In these two orders the superior turbinated bones commence each as a single lamina, which soon forms two.

MAMMALIA.

These are coiled upon themselves in a spiral manner, and make either two or two and a half turns, according to the species, so as to produce a sort of horn or concha, closed posteriorly in a point. This horn contains two canals; the one above, the other below the principal lamina. The superior canal leads to the maxillary sinus in the *cloven-hoofed* quadrupeds, and in the *hog* it is continued posteriorly in a long groove, which ends in a canal that goes into the malar sinus. The inferior canal of the concha conducts into the back of the nasal cavity, as in the human subject.

The turbinated bones are compressed horizontally in the *hippopotamus*, owing to the shape of the animal's head.

The laminae of the turbinated bones are generally in the *hoofed* quadrupeds porous or filled with foramina, which are of various sizes in different species; in some instances the holes are so large and numerous, that the bones form merely an osseous net-work. The *pig*, however, has no foramina in these bones.

In the internal part of the turbinated bone there are several partitions; which are also perforated with vacancies.

In the *solid-hoofed* tribe, according to Cuvier, the horizontal lamina of the inferior turbinated bones does not divide into two, but at first folds downwards, then bends upwards, and is attached behind to the maxillary bone. It ascends posteriorly, to cover the opening into the inferior maxillary sinus, and even to pass into it. Lastly, it produces, towards its middle, two or three oblique laminae, which are attached to the anterior edge of this hole.

The inferior turbinated bones of the *edentata* and *three-toed sloth*, very nearly resemble those described in the *cloven-footed* quadrupeds. In the *two-toed ant-eater*, however, Cuvier says, they are like two prismatic boxes closed on all parts, and divided internally by some vertical laminae. The *lemur* has similar bones, but without any division anteriorly.

In the *porcupine* and *marmot* these bones consist of a double lamina, attached longitudinally; the two parts of which separate from each other, and ascend by a spiral convolution, giving the appearance of the periwinkle shell (*turbo*). The *rat* has the turbinated bones similar to those of the *cloven-hoofed* quadrupeds. The other *saltigrada* almost all have these bones complicated, as in the *carnivorous* tribes.

In these last the lamina, by which the inferior turbinated bone is affixed, divides into two branches, each of which is again divided. The last laminae form a number of canals covered by the pituitary membrane. The air passes through these canals on its way from the nostrils to the lungs, and back again. The *seal* and *otter* have the inferior turbinated bone more subdivided than any other animals of this class. Professor Harwood has calculated that the internal surface is equal to 120 square inches in each nasal cavity of the *seal*. The laminae are most numerous in the *beaver* amongst the *saltigrada*. When there are few laminae in the *carnivorous* and *saltigrade* orders, the last laminae are spirally twisted in the same manner as where there are but two in other animals. The *lion* has the lamina divided into two, each of which has a double roll. It is perforated by many foramina. The *civet* and the *viverra genetta* have only the lamina convoluted and without foramina.

The intention of the divisions and convolutions of the inferior turbinated bones, is evidently to extend the surface of the pituitary membrane which is spread upon them, and as we find this surface, almost without exception, great in proportion to the acuteness of the sense of smell, we cannot but suppose the olfactory nerve is distributed to it, although its branches have not yet been clearly traced beyond the superior turbinated bone.

The *olfactory* nerve has been already described until its

entrance into the nasal cavity. Upon arriving there, its distribution appears to be exactly the same both in man and mammalia. Cuvier mentions two branches, which are longer and plainer than the rest, upon the septum, but these appear to us to be branches of the fifth pair of nerves, distributed to the pituitary membrane for common sensation.

The *sinuses* of the different bones in the neighbourhood of the nasal cavity, more particularly the *frontal* sinuses, have been considered by Blumenbach and others as being subservient to the organs of smelling. We must confess, however, that the use of these parts does not appear to us to be quite determined. The membrane which lines the sinuses is not organized for receiving the impression of odorous effluvia, and the retention of the latter in the cavities of the sinuses does not seem likely to produce much effect upon the pituitary membrane. We may observe, that when animals wish to smell any substance particularly, they make short inspirations, which is called *snuffing*. The chief use of the sinuses, as connected with the organs of smelling, appears to be to supply a clear watery fluid for keeping those parts moist which are really the seat of this sense, for we find, when the secretion of the sinuses becomes inspissated or suppressed by catarrhal inflammation, the sense of smelling is very much impaired.

The *frontal sinuses* vary very much in size and figure, even in the genera of the same tribe. They are small in the *monkey* kind generally, and are even absent in some species. Those with *prehensile tails*, on the contrary, have them large.

The *bats* want these sinuses.

In the *digitigrada* they are large, and particularly so in the *dog* kind, in which they not only occupy the anterior part of the os frontis, but the post-orbital processes, and each side of the posterior parietes of the orbit.

These sinuses are very extensive also in most of the *plantigrada*. The *badger*, and the greater number of the *weasel* kind, want them altogether, but have the post-orbital processes hollow, and communicating freely with the nasal cavity.

Most of the *saltigrade* quadrupeds want the frontal sinuses; yet in the *porcupine* they are so large as to pass into the substance of the nasal bones.

In the *edentata* these sinuses do not exist, in the *ant-eater* and *pangolin*, but the *armadillo* has them of some size.

In the *sloth* they are very extensive, reaching nearly to the occiput.

The *cloven-footed* quadrupeds have the frontal sinuses in general very large, and in the *ox*, *goat*, and *sheep*, they extend into the interior of the osseous process, which sustains the horn. Cuvier thinks the *stag* has no frontal sinuses. Harwood says the *deer* want these sinuses, but have membranous cells between the nose and internal angle of the eye.

The *elephant* has the sinuses corresponding to the frontal of prodigious extent. They give the remarkable prominence of the forehead which this animal possesses, and render several of the bones of the head hollow. They are divided into a great number of smaller cells, so that the texture of the cranium in the elephant has, when laid open, the appearance of a honey-comb, or rather of a sponge that has large cells.

In the *hog* these sinuses are larger than in any other animal, except the *elephant*. They extend in both these quadrupeds as far as the occiput. In the *common hog* and *babiroussa* they are divided by some laminae of bone, but do not form that intricate cellular structure found in the *elephant*. The *hippopotamus* and *rhinoceros* have no frontal sinuses.

These sinuses are of tolerable extent in the *horse*, but are confined

MAMMALIA.

confined to the frontal bone, and in place of opening, as usual, into the superior part of the nasal cavity, communicate on each side, by a large opening, with the posterior maxillary sinus.

The *seal* wants the frontal sinuses.

It will be seen, from the above account, that the magnitude of the frontal sinuses keeps pace in general, though not constantly, with the degree of excellence in which the animal possesses the sense of smelling, from whence the opinion arose, which we have already noticed, of these sinuses being particularly connected with the organ of smelling.

The *maxillary sinuses* are very small in many orders of mammalia, as the *digitigrada*, *plantigrada*, the greater number of the *saltigrada*, and *edentata*, and usually in all the quadrupeds in whom the maxillary bone does not form a floor to the nostrils. They are less in the *monkey* and *lemur* than in man in proportion. Generally in the *digitated* quadrupeds, when there is a cavity in the maxillary bone, it is in common with that of the nose.

Hogs want the maxillary sinus, but they have sinuses in the malar bone. The *hippopotamus* has likewise a small sinus in the same situation. The maxillary sinuses of the *elephant* are cellular, like the others of this animal. The cells communicate, and one of them opens into the nasal cavity.

The *cloven-hoofed* quadrupeds have the maxillary sinuses, as well as the frontal, very large. Each sinus opens into the nasal cavity, behind the inferior turbinated bone, by a narrow slit.

In the *horse* there are two maxillary sinuses, an anterior and posterior. The latter is the larger, and forms a projection into the nasal cavity.

The *sphenoidal sinuses*, although, from the position of the head of quadrupeds, they must perform the same offices as the frontal sinuses, do not correspond with these last in regard to size.

In the *quadrumanæ*, they are less than in man in proportion.

The *carnivorous* tribes have small sphenoidal sinuses, and some of them, as the *otter*, *pole-cat*, and *seal*, want them.

They appear to be absent also in most of the other genera of mammalia. They are found in the *hog* and *hippopotamus*, but of a small size. The *elephant* has them of a very great magnitude. They extend into the pterygoid processes of the sphenoid bone. Their interior is not cellular, as the other sinuses of the *elephant* are.

The sphenoidal sinuses exit in the *horse*; they open into the posterior maxillary sinuses.

The entrance into the organ of smelling, is in general composed of the same cartilages in man and many mammalia, only differing in form and size in the latter.

In those with *snouts*, the cartilages make in general a perfect tube. Cuvier thus describes the snout of the *bear*. The cartilaginous septum is reflected inferiorly as well as superiorly; the superior alæ bend downwards; they meet on the sides, where they are united by cellular substances, and complete the external parietes of each nostril. The edge of each alæ continues afterwards to bend inward, and forms a kind of concha, which makes an addition to the inferior turbinated bone, and which is covered, like it, by a prolongation of the pituitary membrane.

In the *horse*, a great part of the external nares is membranous. The edge of the nostrils contains a semi-lunar cartilage, which corresponds to the inferior cartilage of the human subject. It has two branches, one is long and narrow, and is nearly parallel to the septum; the other is short, almost square, and situated in the external alæ of the nose. The rest of the alæ is formed by the integuments,

which are at first inflected to produce a fossa, which is known by the name of the *fossa nostril*. The passage into the real nares is a long slit.

The proboscis of the *elephant* and *tapir* is the most remarkable prolongation of the external parts of the organs of smelling. The two external nares are extended into two membranous tubes, which in the *elephant* are of great length. These tubes are inclosed by the complicated muscular structure already described, and the integuments.

The muscles which move the different parts of the external nares are described along with those of the rest of the body.

We have before observed, that the *cetacea* do not possess any olfactory nerves, or apparently any organ calculated for receiving impressions from odorous substances. Yet Mr. Hunter ascribed the sense of smelling to the *spermaceti whales*, and Cuvier seems to think, that it may exist, in a degree, in a certain cavity and cells which communicate with the Eustachian tube. These are situated on the lateral parts of the base of the skull, and are partly formed by projections of the bone, and partly by processes of ligament. They are very irregular interiorly, and are lined with a thin mucous membrane. These cells communicate with the frontal sinuses, by a canal which ascends before the orbit. There is a tolerably large opening from the principal cavity into the Eustachian tube. This last terminates in the nares. The cellular cavity, therefore, has no direct communication with the nares. There are several branches of the fifth pair of nerves dispersed through these membranous cells, but there is no reason for supposing that these have any sensibility for odorous substances, even if they were fairly applied to them.

The two canals corresponding to the nares, are used in *cetacea* for the transmission of the air to and from the lungs, as these animals do not respire by the mouth; for the larynx, instead of opening at the back of the mouth, ascends in the form of a pyramid, and is received into a fleshy tube, which is common to the two nares. *Whales*, therefore, can keep the mouth in the water, and swallow their food, without interrupting their respiration, and it is to enable them to do so frequently, that the external opening of the nares is upon the top of the head. The fleshy tube which receives the superior part of the larynx soon divides into two canals, which pass on each side of the vomer, and are analogous to the posterior passages, into the nasal cavity of other mammalia. They are, however, lined by a thin, dry integument, very unlike the pituitary membrane. They ascend in two canals that are formed in the bones of the cranium, separated by a thin septum. Where the two canals terminate, they are provided with a fleshy valve in the shape of two semicircles. This valve is attached to the anterior edge of their orifice, and closes it by means of a very strong muscle, that is attached to the intermaxillary bones. On the outside of this valvular opening, there are placed two large, oval, membranous bags. These are lined by a black mucous integument, which appears to be the continuation of the skin; it is very deeply wrinkled in a relaxed state.

A strong layer of fleshy fibres arises in a radiated manner from the circumference of the cranium, and unites upon these two bags. The skin of the head covers them, and there appears externally only a small slit of a semi-lunar figure, which is a common opening to the two bags.

It is the structure just described which enables the *cetacea* to expel any water which may get into the pharynx or nasal passages. This is done with so much force, that the jet is seen in the larger species at a considerable distance at sea. Some *whales* are reported to spout the water from their blow

blow holes as high as 40 feet. When these animals wish to expel the water from these spiracles, they close the pharynx and larynx by their proper muscles; the larynx retreats from the fleshy tube which embraces it during inspiration, and leaves the passage into the nares free, through which the water is urged to ascend, until it arrives in the oval bags situated on the forehead, which is the upper part of the head in these animals. The valve that guards the opening of the nares into the oval bags is shut, to prevent the retreat of the water; the muscles of the bags contract, and the water is thrown out through the semi-lunar fissure of the skin with extraordinary force.

Fig. 4. Plate XIII. of the *Anatomy of Mammalia*, is a section of the anterior part of the skull and upper jaw of the *hog*, in which most of the circumstances in the structure of the organ of smelling are brought into view: *a*, the frontal sinuses, which are very large in this animal; *b*, the sphenoidal sinuses of a small size; *c*, the ethmoidal cells; *d*, the superior turbinated bone; *e*, the inferior turbinated bone; *f*, the passage to the malar sinus; *g*, the septum dividing the ethmoidal cells from the superior turbinated bone.

Organs of Hearing.—The *concha* and *cartilaginous meatus auditorius*, which constitute the *external projecting ear*, are generally much larger in mammalia than in man. Some, however, that burrow in the ground, are deprived of concha, as the *mole* and some *shrews*, the *zemni* and some *mole-rats*. It is also wanting in the *pangolins*, the *ornithorhynchus*, some *seals*, and the *morfe*. In the *cetacea*, there are no external parts to the ear. The cartilaginous meatus commences by a very small orifice in the skin, and leads to the *membrana tympani*.

The *concha* is large in those mammalia that have occasion to collect distant sounds in the air, as the *bat*, several *cloven-footed quadrupeds*, the *ass*, the *hare*, the *rabbit*, &c. In the fugitive quadrupeds, the concavity of the *concha* is usually turned backwards; and in those that hunt for their food, it is generally directed forwards. In the *bat* kind, the hollow of the ear is turned forwards, probably for feeling the approach of other bodies in the same manner, as the wings of these animals do. The ears of the *vespertilio spasma* are immoveably fixed in the forward direction, as they are united to each other by their internal edges. The superior part of the external ear being pendulous, Cuvier remarks, is an effect of domestication. The ear of the *elephant* is also pendulous, but not in the same way as in domestic animals; it being only the posterior and inferior part of the *elephant's* ear which hangs down.

In proportion as the ear is found larger than in man, it usually becomes also more elongated in its figure: it is also thinner. It is nearly membranous in the *opossum*.

The *eminences* of the external ear are various in mammalia. The most singular peculiarities are seen in the *bat* kind. That remarkable projection which appears like one concha, contained within another in the *great eared bat*, is the eminence called the *tragus* prodigiously enlarged. This part is also unusually formed in the other species of *bat*. It is forked in the *vespertilio spasma*; notched in the *vespertilio leporinus*, and *v. erenatus*.

The *antitragus* is extended forwards in the *vespertilio molossus*, to the angle of the mouth. It forms an operculum to the ear in some *shrews*, particularly in the *aquatic shrew*, which has the opening into the ear perfectly covered by this means.

Quadrupeds often have the cartilaginous meatus auditorius composed of two pieces; one is joined with the concha; the other is a tube which is connected to the bony meatus

by ligament: both pieces have a longitudinal fissure. The design of this structure is to permit the contraction and elongation of the cartilaginous tube of the ear.

In the long-eared quadrupeds also, there is a third cartilage, to which nothing similar exists in the ear of the human subject. It is situated above the cartilaginous meatus; it is flat, and forms no part of the concavity, but merely serves for the attachment of certain muscles. It varies in shape; it is triangular in the *horse*; lunated in the *sheep*; pointed posteriorly, and bilobed posteriorly in the *rabbit*, and rhomboidal in the *dog*. Cuvier, from whom we borrow this account, calls this cartilage the *scutum*.

The external meatus auditorius is long and curiously twisted in the *ornithorhynchus*.

The *muscles* which move the external ear in most quadrupeds are very numerous and complicated; they have received a distinct description along with the other muscles of the body.

The *osseous portion* of the *meatus auditorius* is subject to a good deal of variety with respect to its length and direction. The latter seems to be influenced by the course in which the sounds approach the animal that it is the most concerned to hear. The osseous meatus is singularly formed in the *mole*; it is flattened superiorly and extended on the sides. The *membrana tympani*, which is very large, constitutes its superior parietes; by this means the *mole* is enabled to collect more perfectly the sounds that arise from the earth.

The *whale* tribe have no osseous meatus auditorius, but the auditory passage is long and serpentine; it is made of cartilages and membranes that allow its being lengthened and shortened.

The *membrana tympani* is extensive in general for the acuteness of the sense of hearing. It is also situated more or less obliquely in those that hear well. In the *mole* it is nearly flat, and forms the bottom of the cavity of the tympanum. It is nearly as oblique, according to Cuvier, in the *otter*, *weasel*, and *badger*. In the *pangolin*, also, it is very oblique. Its position is nearly vertical in many other *carnivorous quadrupeds*. It is nearly vertical, and turned towards the side, in the *hare*, *cavy*, *marmot*, and most of the *cloven-footed* order.

The form of the *membrana tympani* depends upon the frame of bone in which it is placed. It is generally in mammalia an oval, with the great axis descending obliquely forwards, and the anterior arch less convex than the posterior. In some of the *saligrada*, the *membrana tympani* approaches the figure it possesses in man; and in the *mole* it is perfectly round. It has the figure of a trefoil leaf in the *cetacea*.

The osseous frame of the *membrana tympani* is only perfect, according to Cuvier, in the *guinea-pig*, the *paca*, the *seal*, and the *ant-eater*. There is in other instances a greater or less deficiency in the upper part of it. This is often about one quarter of its circumference. In the *elephant* the half of the upper part of the osseous frame is wanting.

In the *cetacea* there is no proper process of bone for a frame.

The *membrana tympani* has something of the infundibular figure in all mammalia, except in the *mole*, where it exhibits no concavity on the outer surface.

The structure of this membrane appears to be the same in all the class of mammiferous animals. In the larger quadrupeds there is no difficulty in exposing its three layers, and in the *elephant* the muscularity of the middle layer is said to be clearly demonstrable.

The cavity of the tympanum in most mammalia is dilated at the lower part, usually into a semi-oval or semi-spherical cell. Those of each side produce two eminences that are visible upon the lower part of the skull.

MAMMALIA.

They are seen even in the *prehensile-tailed monkeys*; but are most remarkable in the *carnivorous* mammalia; they are very large in the *cat* kind, and the *seal*. These protuberances are more or less angular in the *stoth*, the *cavy*, the *cloven-hoofed*, and several of the *many-hoofed* quadrupeds. They are flat in the *mole*, and so broad as to touch each other. In the *bear* there are no projections visible. In the *hog* they are elongated, and end in bulbous heads.

The *malloid process* can hardly be said to exist in mammalia. Its place seems to be supplied by the dilatation we have just described. In the *cloven* and *solid-hoofed* quadrupeds, the *hog*, *cavy*, and *guinea-pig*, there is a style-shaped process from the occipital bone, which has been considered as analogous to the malloid process by some anatomists.

The interior of the cavity of the tympanum is, in many genera, more or less subdivided into different parts. A number of the *carnivorous* tribes have a transverse osseous ridge from the frame of the membrana tympani, to which it appears to serve as a support. In addition to this, there is, in the *cat* and *civet* genera, an osseous process, that extends from the posterior inferior edge of the frame of the membrana tympani, to the promontory, and which, being prolonged obliquely, divides the cavity of the tympanum into two unequal parts, that only communicate with each other by a hole. The anterior of these two cavities contains the bones of the ear and the foramen ovale. The posterior cavity is much larger, and holds the foramen rotundum. It seems to correspond with the large cells of birds.

Cuvier states that *prehensile-tailed monkeys* and *ant-eaters* have an additional cell, situated before the cavity of the tympanum, and that the *stoth* has a cell at the root of the zygomatic process.

The interior of the tympanum is intercepted in the *elephant* by a number of bony processes, which cross in every direction, and produce a multitude of cells. A similar structure exists in a degree in the *guinea-pig*, *marmot*, *cavy*, and *porcupine*, according to Cuvier. The two tympani of the *elephant* communicate by the cellular structure of the skull.

The tympanum has osseous septa in the *pig* and horned *bullock*, which divide its cavity into cells like those of a ripe fruit.

In the *hippopotamus* the proper cavity of the tympanum opens by a hole into a cellular cavity.

The *seal* and *moose* have the tympanum very wide, but without septa.

The osseous part of the *Eustachian tube* in the *cat* and *civet*, is rather a narrow fissure than a canal; in the *otter*, *badger*, and *weasel*, &c. it is a hole; in the *cavy* it is a half formed canal at first, which is completed in passing through the petrous part of the temporal bone. In the *elephant* it is a long wide canal.

There is a large membranous sac in the back of the mouth of the *horse*, in which the Eustachian trumpet ends.

In the *cetacea*, the cavity of the tympanum, as well as the petrous portion of the temporal bone, is distinct from the rest of the skull, to which these parts are only bound by ligament and periotteum. The tympanum resembles in figure the sea shell called *bullæ*. The part which corresponds to that containing the spiral cavity in the *bullæ* is, however, solid in the tympanum. This part is more than two inches thick in the *cachalot* (*physeter*). This tympanum adheres to the petrous bone by its posterior extremity, and by a process of the anterior part of its thin edge. Cuvier states that in the *dolphin*, the anterior process of the tympanum also ascends to the petrous bone, but in the *cachalot* (*physeter*) it does not reach that part. The tympanum of the *cetacea* is rough upon the surface. It is very ponderous, from possessing a

great quantity of earthy matter, and is lined with a strong membrane, which Hunter thought had a cuticle. There is a thick plexus of vessels in the cavity of the tympanum, one part of which is attached, and the other floats at liberty, like the plexus choroides in the ventricles of the brain. The Eustachian tube in *cetacea* is widest at its commencement from the tympanum, the anterior extremity of which is entirely open. The tube ascends along the pterygoid process, penetrates the maxillary bone, and terminates by a valvular opening in the nasal passage. Both the tube and the cavity of the tympanum communicate with several ligamentous cells, which Hunter considered analogous to the malloid in some respects.

The two foramina which connect the cavity of the tympanum are so various in their form, that the usual names of *foramen rotundum*, and *foramen ovale*, would be improper. Cuvier, therefore, has called the first the *fenestra cochlearis*, and the second the *fenestra vestibularis*.

In the *bat*, the foramen of the cochlea is larger than the other.

In the *mole*, they have both an oval figure. There is a hollow osseous bar which gives passage to some blood-vessels extended across the fenestra vestibularis in this animal; it passes between the branches of the stapes. A similar bar is found in other instances.

In the *cat* and *civet*, the foramen of the cochlea is almost twice as large as the vestibular fenestra.

In the *opossum*, the foramen called oval in the human subject is round, and the one called round is small and irregular. The latter is triangular in the *beaver* and *marmot*, and in the *bare* it is a small fissure. The vestibular foramen in this last animal is round and large.

The cochlear fenestra is about double the size of the other in the *cat* and *pig*, and three times larger in the *hippopotamus*. But in the *elephant* it is very small and irregularly shaped. It is larger than the vestibular foramen in the *horse*.

The two foramina are farther asunder in the *cetacea* than in quadrupeds. The one of the cochlea is the larger. It has an opening for blood-vessels. The lining of the tympanum projects into the cochlear fenestra.

The same number of *ossicula auditus* are found in mammalia as in man, with hardly any exceptions. The *ornithorhynchus paradoxus* has only two ossicula; the first corresponds to the malleus of other mammalia; the second resembles very much the single ossiculum of birds. Perhaps a mechanism similar, or approaching to this, would be found in some of the other *edentata*. There have been discovered in some of the *cloven-hoofed* quadrupeds one or two small bones in addition to the usual number. These do not appear to be a natural structure. We shall not enter into a minute description of the varieties in the form of the bones of the ear, as many of them do not appear to influence the functions of the organ. We shall only notice the more remarkable peculiarities observed in the ossicula auditus, and refer the reader to Cuvier's "Comparative Anatomy," vol. ii. and Mr. Carlile's paper upon the stapes in the Philosophical Transactions for 1805, &c. for a more particular description of these parts.

The *processus gracilis* of the malleus is formed into a thin lamina at its extremity in some *monkeys*, and in the *dog* and *cat*. In the two latter, the *short process* of the malleus is very prominent, and there is another process at the inner part of the neck of the ossiculum, which supplies the place of the small spine of the human subject.

In the *mole*, the *processus gracilis* is so broad as to make the malleus appear nearly square.

In the *saligrada*, the handle of the malleus is very thin.

It is likewise so in the *stoth*, *ant-eater*, and *pangolin*, and in all these the short posterior process is almost effaced.

In the *seal*, the handle of the malleus is also compressed, and there is hardly any processus gracilis.

In the *cetacea*, the handle of the malleus is different, but its place is in some degree supplied by a tendinous elongation of membrana tympani, which has more of the funnel shape than in the other mammalia, especially on the inner side. This prolongation of the point of the infundibular membrana tympani is inserted into the base of the neck of the malleus. The neck is truncated obliquely, and there is a processus gracilis which is conical and arched in its form.

There is less variation in the forms of the *incus* of mammalia, than in the preceding ossiculum. The *mole* has the most remarkably shaped incus. Its inferior or stapedian process is very short and small; while the other is very large, oblong, and hollowed posteriorly like a spoon. Cuvier imagines this may be for holding a muscle.

The stapedian process is very long, and the other hardly apparent in the *rat* and *hare*.

The existence of the *orbicularis* as a distinct ossiculum has been doubted by some anatomists. Blumenbach considers it only as an epiphysis of the incus. He says it is often wanting even in negroes and North American Indians, whose organs of hearing are very perfect: that it is consolidated with the incus in the adult, and that when it is found as a distinct bone it is not a natural structure. It has appeared, however, to us to be too easily separated, and too regular in its figure, for a mere epiphysis of the incus. It is wanting altogether in the *cetacea*. The *bottle-nosed whale*, according to Hunter, has a small bone in the tendon of the stapedius muscle.

There are several varieties in the figure of the *stapes*, which are pointed out by Mr. Carlile, as above-mentioned.

The form of this ossiculum is most peculiar in the *mole*, and in the *aquatic mammalia*. The former has the branches of the stapes very much arched and far asunder. The base of the ossiculum is an elongated oval shape. In the *cetacea* the parts corresponding to the branches are so thick and close to each other, that the stapes appears as a solid bone, with a very minute foramen in the middle. The base is small in proportion to the rest of the ossiculum. In those species we have examined, the foramen was only large enough to admit the point of a pin. Cuvier describes the stapes of the *lamantin* as resembling a twisted cylinder: on one side there is an oblique groove, and the foramen has the appearance of the puncture of a pin. The surface of the base applied to the fenestra vestibularis is very convex. Some approaches to this structure of the stapes has been observed in the *seal*, from whence it has been supposed, that a solid state of this ossiculum was favourable to hearing sounds communicated through water.

The *muscles* of the bones in the tympanum have not received as much investigation as they merit, either in man or animals. The same number appear to exist in mammalia as in man, with the exception of the *cetacea*, which seem to want all the muscles inserted into the malleus. They have, however, the *stapedius* muscle. Cuvier says, it is inserted very far up, and not in the middle of the branch of the ossiculum, as in man.

The *labyrinth* consists of the same parts in mammalia as in man. The *semi-circular canals* were at one time not supposed to exist in the *cetacea*. They are so extremely small that they even escaped the notice, for a long time, of so accurate an anatomist as Camper. In the *porpoise* we have found them just large enough to admit a bristle to pass in them. The extreme hardness and brittleness of the petrous

bone in *cetacea*, are additional reasons for these canals remaining undiscovered, and stand in the way of investigating all the parts of the organ of hearing in these animals. This bone, and indeed the tympanum also, in *cetacea*, are as dense and weighty as common stone, and when dried are very easily broken in all directions. The petrous bone is not united, even by suture, with any of the other bones of the cranium, but is retained by ligament and periosteum in a vacancy formed principally in the occipital bone.

The *mole*, whose organ of hearing, in many respects, is formed upon an opposite plan to that of the *cetacea*, is distinguished by the extent of the semi-circular canals, and these are plainly seen on the inside of the cranium, from not being imbedded in a bone harder than the rest of the cranium, as usual in other cases.

Some mammalia are remarkable for the great size of their *cochlea*, in proportion to their parts of the ear. The *bats* have it of the greatest relative size. Cuvier states, that the *horse-shoe bat* has the diameter of the cochlea ten times greater than that of one of the semi-circular canals. The cochlea is visible in this genus on the lower part of the cranium, generally where its form is distinctly exhibited without any dissection of the temporal bone. It bears a perfect likeness to the snail-shell. The semi-circular canals are visible on the internal part of the cranium. There is no petrous portion, properly so called, either in the *bat* or the *mole*, except what constitutes the labyrinth itself. In the *hare-lipped bat*, according to Cuvier, the cochlea projects on the inside of the cranium.

In most of the *carnivorous tribes* of mammalia, the cochlea is larger in relation to the semi-circular canals than it is in the human subject. It is, likewise, so in the *hog*, *elephant*, and *horse*. On the contrary, the relative size of the cochlea to the canals, is less in the *mole* and *hare* than in man.

In general, the cochlea forms two turns and a half in mammalia, as in man. But the *guinea-pig*, *cavy*, and *porcupine*, have three turns and a half. Their cochlea has a pyramidal figure, and makes a projection into the cavity of the tympanum.

The cochlea of *cetacea* is very peculiar. It is large, but only forms one turn and a half, which is nearly in the plane of its axis. The osseous *lamina spiralis* is divided throughout its length by a very narrow fissure into two parts. That which touches the axis is three times larger than the other. The fissure is only completed in the recent state by a membrane.

The osseous part of this septum also, which touches the axis, has under its base, and in the scala of the tympanum, a small canal, which follows the same curvature from one extremity of the cochlea to the other. This canal appears like a third *scala* to the cochlea, but it differs in the circumstance of its capacity increasing as it proceeds in the cochlea; it is widest at the apex. Cuvier observes, that there is a similar canal, though much smaller, in the *clown-hoofed* quadrupeds. In the other mammalia, only the part of the lamina spiralis which touches the axis is osseous, as in man.

According to Cuvier, the *dog*, *stoth*, *elephant*, *horse*, *dolphin*, &c. resemble man in having the scala of the cochlea that goes to the tympanum rather larger than the other. It is much greater in the *bat*. The scala that leads to the vestibulum, is the larger in the *calves*, *goats*, *sheep*, *hare*, *cat*, *guinea-pig*, *rat*, &c.

The *aqueducts*, as they are called, appear to exist in all mammalia. They have been observed to be very large in the *dolphin*.

MAMMALIA.

The figures which illustrate the organ of hearing, are found in *Plate XIII.* of the *Anatomy of Mammalia.*

Fig. 5. represents the under surface of the skull in the *mole*, the lower jaw being removed: *a* is the flat dilatation of the cavity of the tympanum, analogous to the mastoid cells, seen externally on the left hand side: *b* is the round, level, *membrana tympani*, exposed on the other side by the bone being cut away: *c*, the osseous meatus auditorius. *Fig. 6.* shews an undivided view of the bone, containing the organ of hearing in the *grampus*, removed from its connections with the skull: *a*, the bone which forms the tympanum: *b b*, the extensive slit-shaped opening into the cavity of the tympanum, and which has been compared to the aperture of the *bull's* shell: *c*, the irregular trilobed space left for the attachment of the *membrana tympani*: *d*, the part of the petrous bone containing the labyrinth. *Fig. 7.* is a view of the malleus of the *mole*. *Fig. 8.* shews the same bone in the *hare*. *Fig. 9.* is the short, thick malleus of the *grampus*, with the *membrana tympani* attached to it: *a*, the ossiculum: *b*, the infundibular *membrana tympani*, with its elongated point inserted into the neck of the malleus. *Fig. 10.* gives the shape of the incus in the *mole*: *a* is the hollow process of the bone. *Fig. 11.* is the incus of the *grampus*. *Fig. 12.* exhibits the stapes of the *mole* in situ: *a*, the ossiculum: *b*, the osseous bar that crosses the fenestra vestibularis between the branches of the stapes: *c, c*, are the surrounding parts of the temporal bone left in the dissection. *Fig. 13.* gives a side view of the stapes in the *grampus*, in which is shewn the small aperture that corresponds to the space left between the limbs of that bone in other mammalia. *Fig. 14.* is a view of the lower part of the interior of the cranium in the *mole*: *a* indicates the labyrinth as it appears, without any dissection of the bones of the cranium: *b*, the semi-circular canals and cochlea exposed, by cutting away some part of the cranium, which is very loose and cellular in its texture, adjoining the osseous labyrinth in this animal. *Fig. 15.* is a representation of the osseous labyrinth of the *bat*, removed from the skull, and a little magnified: *a*, the semi-circular canal: *b*, the very large cochlea: *c*, the foramen cochlea fenestra: *d*, the vestibular fenestra. *Fig. 16.* exhibits the turriculated cochlea of the *guinea-pig*, laid open on one side, to expose the three turns and a half made by it in this animal. *Fig. 17.* shews the cochlea and part of the semi-circular canals of the *grampus*, excavated from the petrous bone: *a, b*, the two tubes which form the cochlea: *c, d*, parts of the semi-circular canals exposed and laid open in making the sections of the bone in which they are inclosed: *e* is the portion of the petrous bone left in the dissection. *Fig. 18.* shews the entire cochlea of the *whale*, abstracted from all surrounding bone; at the extremity are seen the openings into the two tubes of the organ. *Fig. 19.* is a lateral view of the same cochlea: *a, b*, are the two small openings of the cochlea: *c* is the beginning of a ridge which divides the entrance of the cochlea: *d*, the tube, which appeared to Camper to contain a nerve.

Organs of Vision.—The eye is composed of the same coats and humours in mammalia as in the human subject. The comparative anatomy of the organs of vision in this class, relates to varieties in the structure of particular parts, with a description of a few appendages to the eye, that do not exist in man.

There is some diversity in the external figure of the eyeball in different mammalia. Agreeable to a general principle already laid down, it is more globular, or the anterior part is more gibbous, in proportion to the tenuity of the medium, through which the animal beholds objects. We therefore find that eyes of the *aquatic* mammalia are most flat upon the

anterior side, in which circumstance they approach in form the eyes of fishes.

The departure from the spherical form of the eye is indicated by a table published in Cuvier's "Comparative Anatomy," in which the length of the axis is compared with that of the transverse diameter of the eye. We shall extract the following examples.

	Axis.	Transverse Diameter.
<i>Man</i> - - -	1	to 1
or, to be more accurate	137	: 136
<i>Monkey</i> - - -		the same
<i>Dog</i> - - -	24	to 25
<i>Ox</i> - - -	20	: 21
<i>Horse</i> - - -	24	: 25
<i>Porpoise</i> , measured externally	2	: 3
<i>Whale</i> , measured internally	6	: 11

Both the permanent and changeable forms of the eye-ball depend necessarily upon its external parietes, which are the sclerotic coat and cornea.

The *sclerotic coat* has the same texture, and proportionate thickness of its different parts, in mammalia generally as in man. There are, nevertheless, some striking exceptions to this observation in the *aquatic* tribes. The sclerotic of the *seals* is thick and firm at the anterior, and still more so at the posterior parts of the eye; but around the middle this coat is very thin and pliant. This change of the strength of the coat is not, however, abrupt. Blumenbach attributes to this structure the power of accommodating the form of the organ to the different media in which these animals reside. The cornea of the *seal* tribe is also thin and yielding, and the muscles which act upon the eyeball are strong. The result of all these circumstances is, that the creature can elongate and shorten the axis of the eye according to the occasion, and thereby adapt it to vision in the two media of air and water.

D'Albus has discovered a similar conformation of the sclerotic in the *walrus*, in which it is also obviously intended to answer the same purposes.

The sclerotic coat of the eye in *cetaceous* mammalia is very peculiar. It is prodigiously thick at the posterior part; in the larger species about an inch and a half; in the *grampus* about $\frac{3}{4}$ ths of an inch; and in the *porpoise* two or three lines thick.

It gradually declines until it arrives at the cornea, where it possesses the ordinary thickness of the sclerotic, in proportion to the size of the animal. The composition of this coat is equally curious with its form. Upon dividing it, we find a multitude of ligamentous fibres passing through it in all directions, and forming an inextricable plexus, which contains in its meshes a brown fungous elastic substance. A section of the sclerotic has very much the appearance of that of tanned leather, only that it is paler. The coat is looser in its texture, and softer quite at the back part, than on the sides of the eye-ball. The meshes there contain an oily substance. The sheath of the dura mater, which contains the optic nerve, is necessarily very long, and is very easily demonstrated in the *cetacea*. The fibres which enter into the composition of the sclerotic are seen to depart from the external part of the sheath, which fact has been taken as the proof of the sclerotic coat being, in all cases, a production of the dura mater, as supposed by the ancient anatomists. The sclerotic of the *whale* kind, by its great firmness, defends the internal parts of the eye from pressure, to which they would otherwise be subject, from the shallowness of the orbits. The form of the internal part of the organ is

MAMMALIA.

also altered to nearly an oval, although the external figure is spherical.

The *transparent cornea* generally resembles that of the human subject in the class of mammalia. The *porcupine* and *opossum* have this part large, and forming the same sphere with the sclerotic. Blumenbach says the cornea of the *porcupine* extends over half the globe of the eye.

The distinction between the cornea and the sclerotic, which is generally but an apparent change of structure, is very clearly to be traced in some of the large animals, in which these two coats can be separated. In the *whales* and the *rhinoceros*, the attachment of the sclerotic to the cornea is by the fibres of the former passing into the latter. In the *ox*, &c. the line of separation can be seen to be oblique, the cornea passing a little under the edge of the sclerotic. In the *hare* and others, the edge of the sclerotic is double, and embraces on both sides the margin of the cornea.

The *tunica conjunctiva* is, especially in the large quadrupeds, less adherent to the eye-ball than in man. Mr. Pierce Smith has professed to trace not only the conjunctiva, but the expansion of the straight muscles over the cornea. The plainest evidence of the continuation of the conjunctiva over the front of the cornea is found in the *zemni rat* (*mus typhlus*), which has the conjunctiva retaining the structure of the true skin, and even covered with hair, so that the eye is altogether useless, or at most can faintly discern the difference between light and darkness. The eye of this animal is said to be not larger than a poppy seed. In the *mole*, also, the eye is extremely minute, and so much shut in by the hair on the eyelids, that it does not appear to be capable of seeing any object distinctly: indeed the eyes of the *mole* are so much concealed, that they are supposed by common people to be wanting altogether.

In the *whale* and the large quadrupeds, the distinction of the two layers of the *choroid coat* is very perceptible. The internal layer, or *membrana Ruyfchiana*, is particularly plain in the *whale*.

Mr. Thomas has discovered a most curious apparatus connected with the choroides in the *East Indian rhinoceros*. Four tendinous processes arise from the back part of the sclerotic coat, expand anteriorly, and form a species of muscular membrane, which is lost in the choroides at the broadest diameter of the eye-ball. It is easy to conceive that this structure can produce material alterations in the figure of the eye, and in the distance of the crystalline lens from the retina, but we cannot conceive why so great a power of adjustment in the eye to different distances should belong exclusively to this animal.

The *pigment* of the internal surface of the *membrana Ruyfchiana* is of various colours in mammalia, particularly on the back of the eye. The *monkey* has it dark coloured. The *hare*, *rabbit*, and *hog*, have it a brown: but in many other mammalia the pigment upon the back of the eye has light and vivid colours. It is called, in these cases, the *tapetum lucidum*. The *ox* has the back of the eye a green, which is lost in an azure blue. In the *sheep* it is a pale yellow-green, or sometimes blueish. Some anatomists, who seem to have confined these observations to those two cases, have conjectured that the use of the tapetum is to reflect the natural colour of the animal's food. But the absurdity of this opinion is shewn by the varieties of the colour of the back of the eye in other animals.

The tapetum is a silvery blue, changing to violet in the *horse*, *goat*, *buffalo*, and *stag*. It is a pale golden yellow in the *lion*, *cat*, *bear*, and *dolphin*. It is a pure white, terminating in blue, in the *dog*, *wolf*, and *lark*.

The shape of the coloured portion of the Ruyfchian coat is irregular, and is situated chiefly upon the temporal side of the entrance of the optic nerve: but in the *whales* the whole of the Ruyfchiana is a silver colour; the ciliary processes and back of the iris alone being dark. The use of the tapetum is not very obvious. The most probable opinion respecting it is, that it enables animals to see better in the dark.

The *ciliary processes* do not appear to differ in their structure in this class and in the human subject. It is true they are very prominent in the large species, and the denticulation of their edges is so much increased, as to form a rich fringed appearance, particularly in the *rhinoceros* and *whale*. The laminae of these processes are long and narrow in the *cat* kind, more especially in the *lion*.

Mammalia have the *iris* usually of a more uniform colour than in man. In *domestic quadrupeds*, however, there is considerable variety in this respect. The colour of the iris corresponds so much with that of the hair, that in *spotted dogs*, &c. the iris is often of a mixed colour.

In the large mammalia the iris is of considerable thickness, but no difference of structure has been perceived.

The *uvea* is found much more plain in the *ox*, *rhinoceros*, and *whale*, &c. than in man, and the stræ that are continued upon the uvea from the ciliary processes, are very distinct in these species. They extend in the *rhinoceros* nearly to the edge of the pupil.

The *pupil* of the eye has various forms in some mammalia.

It is in the *cat* kind a vertical slit, over which these animals have great command, sometimes contracting it to a mere line, and at others dilating it to nearly a round figure. In the *cloven-hoofed* order, the pupil is a transverse slit, with the ends of the slit wider than the middle. In the *horse* it is also transverse, but the superior edge projects a little way. This has been compared to the curtain that hangs over the pupil in the *skate* by Swammerdam, although there is but little resemblance between the two parts.

It is a transverse oblong aperture in the true *whales*, and in the genus *delphinus* it is a heart shape.

The *retina* is formed usually in the same manner in mammalia as in man. It sometimes happens that the *optic nerve*, immediately on entering the cavity of the eye, forms a slight projection. In the *hare* and *rabbit*, this projection is described as producing a kind of oval cupola, which is slightly concave in the middle. The retina arises from the edge of it. The fibres of the nerve are condensed on each side into two streaks or pencils, which are a more opaque white than the other parts of the retina. In almost all mammalia the retina has at its origin the appearance of its substance being collected into folds, or fibres, which arise in a radiated manner.

Comparetti states, that the optic nerve of the *bat* perforates the sclerotic coat by a number of foramina. The filaments, thus formed, unite to produce the retina.

The *foramen* of the retina, which usually takes the name of Sömmerring, has not been found in any of this class, except the *monkey* tribe. Cuvier states, that he found it in the *syncephalus* considerably larger than in man, and of an oval shape.

It is singular, that although this foramen does not exist in the *lemur*, yet the fold which contains it in man and the *monkey* is found. The uses of the foramen of Sömmerring are not yet determined. Mr. Home imagined that it gave exit to an absorbent vessel; but it is much more probable that its existence is connected with the position of the eyes, as it is only met with in those that have the eyes placed so

MAMMALIA.

that their axes are parallel. Blumenbach observes, upon this subject, that when the two eyes are situated, as in man and the *monkey*, they are liable to be both dazzled at the same time, by an exposure to a strong light, as the rays fall upon the corresponding principal focuses of both eyes at once. He concludes, that the foramen of Sömmerring being in the principal focus, the rays pass through it, and are suffocated in the pigment of the choroid coat. But to produce such an effect, without weakening vision at all times, would require a muscular power to open and shut the foramen according to circumstances, nothing of which kind appears to be provided.

The aqueous humour of the eye would appear to be in less quantity, according to the bulk of the organ in mammalia, than in man.

The crystalline, on the contrary, occupies less space in proportion to the other parts in man than any of the mammalia. It is also more of a spherical figure in all this class than it is in the human subject. Blumenbach states, that he found the crystalline to be largest in relation to the vitreous humour in the *Virginia opoffum*. We select the following instances from a table founded on the observations of Petit and Cuvier, to shew that there is a scale, from man to the *cetacea*, with respect to the form of the crystalline, by which it will be found, that the lens is least spherical in the human subject, and most so in the aquatic mammalia.

The axis of the crystalline is to the transverse diameter,

In <i>Man</i> , as	-	-	1 to 2 generally.
<i>Monkey</i>	-	-	the same.
<i>Ox</i>	-	-	5 to 8
<i>Horse</i>	-	-	2 : 3
<i>Dog</i>	-	-	7 : 9
<i>Hare</i>	-	-	4 : 5
<i>Otter</i>	-	-	4 : 5
<i>Porpoise</i>	-	-	9 : 10
<i>Whale</i>	-	-	13 : 15

In the *cetacea*, therefore, the lens is nearly a perfect sphere, as in fishes.

The vitreous humour of man is more abundant, in proportion, than that of mammalia. Thus, the human vitreous humour is twenty times larger than the aqueous, while, in the *ox*, it is only ten times as large, and in the *sheep* but nine times the size of the aqueous humour.

The oblique muscles of the eye-ball do not differ from those of the human subject; but the straight muscles are more numerous, except in the *monkey* kind. In many there is but one additional muscle, which encloses the back of the eye and the optic nerve, as if in a funnel. It arises, like the other recti muscles, from around the optic foramen, and is inserted into the sclerotic behind them. This muscle is called the *suspensory*, *chanooid*, or *retractor* of the eye.

The suspensory muscle is divided into four slips, or, as some might state it, there are four additional straight muscles in most of the carnivorous mammalia, and the *cetacea*.

In the *rhinoceros* there are only two portions corresponding to the suspensory muscles.

In all mammalia, we find the four recti muscles as in man, independently of the suspensory above-mentioned.

The third eye-lid is considerably developed in many quadrupeds. It is usually semi-lunar in its figure. In the *hare*, *rats*, *agouti*, &c. its free edge is convex. In many cases, it contains a thin cartilage, which, from a supposed resemblance to a nail, is called *unguis*. This cartilaginous plate is broad and triangular in the third eye-lid of the *hare*. There is almost always a row of pores upon this eye-lid, which discharge an unctuous fluid. The third eye-lid is large in the

cat genus, the *opoffum*, the *seal*, and particularly so in the *elephant*.

There is no trace of the third eye-lid in the *cetacea*, and the two usual eye-lids are so much thickened by the adipose substance, that they have scarcely any motion. They seem half closed, but, we believe, are never completely shut, the constant residence of these animals in water not making it necessary.

The lacrymal gland exists in mammalia, except the *cetacea*.

In the *hare* and *rabbit* it is extremely large. It nearly encompasses the eye, and even passes out of the orbit on the side of the nose. Cuvier thinks it has but one excretory duct.

The lacrymal gland in the cloven-footed quadrupeds is divided into two or three masses. Some separate grains have each a very short excretory duct.

The puncta lacrymalia, and the nasal duct, for carrying off the tears, have been observed in the *bisulca*, *hog*, *stoth*, and *ant-eaters*, &c. and probably are to be found generally. Camper, however, denies the puncta lacrymalia, lacrymal sac, and even the *os unguis* to the *elephant*. Some anatomists have considered cells below the internal angle of the eye in the *deer* and *antelope* genera as receptacles for the tears; but these fossæ, as already mentioned, in describing the excretory glands, have no connection with the lacrymal passages and contain an unctuous matter.

In the *hare* and *rabbit*, the puncta lacrymalia are supplied by a semi-lunar fissure, which is placed under the inferior edge of the third eye. The border of this slit is provided with cartilages to keep it open. There is a single lacrymal duct, and a small valve in the canal, to prevent the tears returning upon the eye. There is no apparatus for the secretion of tears in the *cetacea*. Thus, constant residence in the water is sufficient to keep their eyes moist.

In many mammalia there is an additional gland to the eye, which, from an anatomist that described it, has been called *glandula Harderi*. It is placed near the inner angle of the eye-lids, and discharges its secretion, which is a thick unctuous fluid, through an opening under the third eye-lid. The *glandula Harderi* consists of small lobes, and resembles very much the true lacrymal gland in its structure. There would seem to be two glands of this description in the *hare*, one is a white colour, the other red; but both apparently have the same structure. They are connected by cellular substance. This gland is large and double in the *water rat*. It is single, oblong, and hard in its texture in the cloven-footed quadrupeds. It has been found oval in many others. There are some fetaceous follicles under the upper eye-lid of *cetaceous* mammalia, which probably fulfil the same purposes as the *glandula Harderi*.

In Plate XIV. of the *Anatomy of Mammalia*, fig. 1. exhibits a section of the eye of the *seal*, in the direction of the optic nerve: *a* is the anterior part of the sclerotic coat, which is thick; *b*, the posterior part, still thicker; *c*, the middle portion, which is thin; *d*, the cornea; *e*, the optic nerve; *f*, the vitreous humour; *g* is the crystalline lens, which is seen to approach the figure of a true sphere. Fig. 2. represents a similar section of the eye in the *grampus*: *a* is the optic nerve passing in the canal formed in the sclerotic coat at *bb*. That coat is also shewn to derive its white fibres from the sheath of the optic nerve; *c*, the cornea; *d*, the ciliary processes; *e*, the membrana Ruyschiana; *f*, the choroides. Its two layers are a little separated, to shew them more distinctly. Fig. 3. is a view of the interior of the front of the eye in the *ox*, produced by the vertical section of the organ: *a*, the divided coats; *b*, *b*, the fringed ciliary processes; *c*, *c*, the striæ of the uvea; *d*, the transverse

MAMMALIA.

verfe pupil. *Fig. 4.* is the front of the eye in the *cat*, with the cornea removed, to fhew the vertical flit produced by the pupil in this genus. *Fig. 5.* is a fimilar preparation of the eye of the *porpoife*, to fhew the figure of its pupil. *Fig. 6.* is a view of the eye-lids in the *bare*, with the aperture into the lacrymal duct: *a, b,* the upper and lower eye-lids; *c,* the third eye-lid; *d,* the fiffure correponding to the puncta lacrymalia. *Fig. 7.* exhibits the glands of the eye in the *bare*: *a* is the lacrymal gland; *b,* the white glandula Harderi; *c,* is the red-coloured one.

Weapons and Organs of Defence.—There is no animal fo unprovided with the natural means of protection or defence as man. His ftrength and his fecurity depend upon the focial intitutions eftablifhed by his fpecies. It is true many of the mammalia are not furnifhed with natural arms, but in place of them, they are endowed with great fwiftnels of foot, and an acute fenfe of hearing, as may be obferved in almoft all the *faligrade* quadrupeds, and others which are purfued by the bealts of prey. Some fugitive animals feek fecurity in concealment, as the *digging* and *diving* quadrupeds, for example the *mole*, the *duck-billed* animal, &c.

The various coverings of mammalia, fuch as *hair*, *hoofs*, *scales*, *fpines*, &c. not only ferve to fhelter quadrupeds from the inclemency of the weather, but from the attacks of hostile animals. The ftong tough hair of the *ant-eaters* and *foth*, the fcales of the *pangolin*, the fpines of the *bedge-bog* and *porcupine*, and, moft of all, the bands of the *armadillo*, are well calculated for this purpofe.

Thofe quadrupeds that have defensive integuments, have generally the power of rolling themfelves up, fo as to conceal the head, feet, and under parts of the body, which are commonly unarmed. The mufcles that are defigned for the contraction of the body, are defcribed with the other organs of motion.

The moft powerful weapons of mammalia are their horns, their teeth, and the hard fubftances with which their toes are armed. The ftructure and growth of each of thefe parts are defcribed in their proper place.

The horns are generally employed as the means of *defence*, and chiefly belong to quadrupeds that are gregarious and inoffenfive, unlefs much irritated, or during thofe periods in which they are under the excitation of the fexual or parental inftincts.

The teeth are the weapons moft commonly employed by animals; almoft every quadruped may be provoked to make ufe of them; even man himfelf, in thofe ftates of fociety where rules of combat are not acknowledged, always recourts to his teeth, when preffed by an adverfary. As the teeth are the moft general weapons of animals, they are alfo the moft deftructive in the operation; when any animal kills another, it is moft commonly by means of its teeth. The large teeth called *tufks*, although generally incapable of being employed in any other way than as weapons, are lefs dangerous than the fmall front teeth of many animals. Some tufks, although fo formidable in their appearance, are very harmlefs in fact. The tufks of the *babirouffe* are fo much turned backward, that they cannot inflict a wound, and thofe of the *elephant* and *mammoth* feem incapable of injuring a fmall animal. The tufks of the *narwhal* are faid to be terrible weapons, which their direction, length, and pointed figure render very probable; there being alfo fo frequently one of them wanting, it is likely that it may have been loft in combat.

The feet of quadrupeds are amongft their moft effectual weapons when they are furnifhed with claws, as in moft of the bealts of prey. The ftrength of the limbs in all predaceous quadrupeds has already been remarked. The

mechanifm of their feet, by which the claws are inverted by the very act of grasping any object, is fingularly ufeul to thofe animals.

Some of the mammalia poffels a great fecurity from the affaults of others, in certain excretions produced by peculiar glands, fituated commonly in the neighbourhood of the anus. Thefe excretions have a difagreeable fmell, which is probably particularly offenfive to thofe animals they are intended to repel. Some of the American fpecies of *viverra* are faid to occafion fo ftong a fœtor by the expulfion of the contents of their anal glands, that it is difcerned at the diftance of two miles, and cannot be immediately approached by any perfon without the greateft danger. The organs which furnifh thefe fœtid matters are defcribed along with other *excretory* glands.

Organs of Voice.—The *monkey* tribe, which have in moft parts of their anatomy fo ftong a likenels to the human body, have many ftriking and important peculiarities in the organs of voice, fome of which are even poffelled by the *ourang-outang*.

This animal has the *arytenoid cartilages* fmall, and the *cuneiform* ones larger than in man. The *cordæ vocales* are loote and fharp upon the edge. The ventricles of the glottis are large oval cavities, and partially divided by a partition. The fuperior part of each ventricle leads into a hole, which is fituated between the thyroid cartilage and the os hyoides, and is the opening of a large membranous fac. Thefe two facs lie under the fkin of the throat, and are in contact with each other, and defcend towards the cheft. Thefe facs, in fome individuals, are of different fizes according to Camper's obfervations. Blumenbach found the right fac three inches long and two inches round, and the left only the bulk of a nutmeg in the *pigmy ape* (*fmia fylvanus*.)

In many other *monkeys* there is one large pouch or membranous fac, which communicates with the glottis. This fac has been defcribed by Camper in the *Barbary ape* (*fmia inuus*), and the *common baboon* (*fmia fphinx*). The opening from the glottis in thefe cafes is in the middle, at the root of the epiglottis, immediately above the thyroid cartilage. Vic d'Azir alfo difcovered the fame kind of fac in the *ribbed-nofe ape* (*fmia maimon*), in which it is very large, and has a round opening under the epiglottis. Cuvier found a fimilar laryngeal fac in the *bare-lipped ape* (*fmia cynomolgus*), and a very large one in the *fmia veter*. It has been defcribed in the *varied ape* (*fmia mona*); but Cuvier denies there being any appearance of it in this fpecies, and even of the hole or depression at the bafe of the epiglottis, which exifts in fome *monkeys* that do not poffels a laryngeal fac, as in the *great baboon* (*fmia hamadryas*), the *red ape* (*fmia rubra*), and the *Chinefe ape* (*fmia fmica*).

In the *filky monkey* (*fmia marikina*), the laryngeal fac has its opening between the cricoid and thyroid cartilages.

The *howling baboon* (*fmia beelzebub*), and the *fmia feniculus*, have the laryngeal facs inclofed in a bony cafe, which is hollowed out in the os hyoides. Camper defcribed but one fac, which he ftated to communicate with the larynx by an aperture between the os hyoides and the thyroid cartilage. Vic d'Azir alfo found but one fac, which he defcribed as being of an irregular pyramidal figure, fituated under the tongue between the two branches of the lower jaw, with its pointed part forwards, and divided interiorly by feveral thin projections of bone. It had a wide opening pofteriorly, above which was placed a bony plate, with two projections at its two extremities. The opening

MAMMALIA.

of the sac communicated with a large, firm, membranous tube, which proceeding horizontally backwards, terminated in the larynx between the *alæ* of the thyroid cartilage, so as to form a communication with both the ventricles of the glottis. The thyroid cartilage was remarkably large, and projected downwards: from its cornu on each side there passed a ligament to the two projections of the bony sac. The thyroid cartilage had a projection where it terminated, which seemed to divide the canal leading from the bony sac into two channels: such is the description given by Vic d'Azir of the organ of voice in the *howling baboon*. Cuvier, however, states, that in the *simia fetidulus* each ventricle leads into a membranous sac, which glides between the epiglottis and contiguous *ala* of the thyroid cartilage, and proceeds towards the *os hyoides*. In the individual which he dissected, the right sac alone occupied almost the whole of the cavity in the *os hyoides*; the left terminated at the moment when it was to enter that bone: but he conceives, that in other individuals, the sacs were of equal size, or that the left might even be the larger of the two.

The effect of all these cavities connected with the larynx is to increase the resonance of the voice. The cartilaginous frame of the larynx and trachea in all animals has the same operation in a greater or less degree; for if the *cordæ vocales* could only occasion the parts immediately adjoining them to vibrate, the sound which they would produce would scarcely be audible. The power of hollow parts in multiplying sound, or rendering it loud by a secondary vibration, is strikingly exemplified in the difference observed between the *common* and the *mute fiddle*. The body of the latter is a narrow solid piece of wood, and although the tones are the same as those of the common fiddle, they are so faint as scarcely to be heard. The influence of the laryngeal cavities upon the voice is clearly shewn in those animals which possess them. The *howling baboons*, that have the best contrived apparatus for increasing the voice, are said to utter a cry which is really terrific.

One species of *monkey*, the *simia paniscus*, has a different kind of dilatation than is found in the rest of this tribe. It is a very considerable enlargement of the membranous part of the trachea immediately behind the cricoid cartilage. The muscles which go from the larynx to the pharynx compress this sac, and urge the air it contains in a stronger current through the parts that immediately produce the voice.

Cuvier describes in this monkey, and in all those of the continent of America, a peculiarity in the structure of their larynx, by which their voice is rendered soft, like the tone of a flute, and they are therefore called *whistling monkeys*. This peculiarity consists in the smallness of the arytenoid cartilages, and the great bulk of the cuneiform cartilages, which, increased by some fat cellular substance, form before the superior extremity of the ventricle of the glottis a large cushion, having the figure of a segment of a sphere on each side. It follows from this structure, that the air which has vibrated in the ventricles has to go through a narrow canal, curved in the figure of an S, which is formed by the opposition of these cushions and the concavity of the epiglottis.

In the *simia jacchus*, and the *simia midas*, the cuneiform cartilages are so large, that their superior projection even divides the upper part of the glottis into two, so as to give it apparently a resemblance to the larynx of birds.

The *os hyoides* is large and round on the front, even in those *monkeys* which do not possess laryngeal sacs, as in the *simia apella* and the *simia capucina*.

In the *lemur*, the superior ligaments of the glottis are

very prominent, and there are between them and the epiglottis depressions, which might be considered perhaps as superior *cordæ vocales* and ventricles.

The epiglottis of the *bats* is soft and hardly perceptible. Its existence has been denied by Vic d'Azir. The *cordæ vocales* also are very indistinct. In the *vampyre bat*, there is a slight membranous projection in place of epiglottis.

In the *dog* genus the *cordæ vocales* are prominent, thin, and free; the ventricles are deep; and the membrane which lines them is wider than they are. The cuneiform cartilages have the shape of an italic S. The looseness of the *cordæ vocales* and the membrane of the ventricles, no doubt tends to produce the *barking* voice of these quadrupeds.

In the *cat* genus, the anterior ligaments of the glottis are, as in the *dog*, contiguous to the internal parietes of the epiglottis, but are separated by a wide deep groove on each side. The posterior ligaments, or *cordæ vocales*, are not loose or sharp. There are two small thin membranes near them, which, when they vibrate, produce the *purring* sound of the *cat's* voice. Cuvier thinks, that the anterior ligaments of the epiglottis constitute the *cordæ vocales* of the *cat*, the ventricles being so very shallow.

The *ichneumon* and *civet* have the organs of voice similar to those of the *cat* genus.

In the *badger*, the ventricle is open, and leads into two pouches, one of which extends forwards under the root of the tongue, where it is only separated from that of the opposite side by the *hyo-epiglottidei* muscles; the other goes backwards between the thyroid and cricoid cartilages. The sound of the voice in this animal appears to be occasioned by the vibration of the breath against the posterior edge of the anterior ligament, when it is driven with force into these two pouches. There are similar pouches in the *weasel*, but the anterior has less extent.

The *marsupial* animals have the larynx peculiarly formed.

In the *kangaroo* the arytenoid cartilages are very large, their superior edge forms the two-thirds of that of the glottis. The cuneiform cartilages, the anterior ligaments, and the ventricles of the glottis, do not exist in this animal, and it can scarcely be said that there is even any posterior ligament or *cordæ vocales*. Cuvier is disposed to think that the *kangaroo* is very nearly mute.

The *American opossum* has also the arytenoid cartilages of great size, and the thyroid cartilage concave. The superior ligament of the glottis is wanting, as in the *kangaroo*. The *cordæ vocales* are very small, and scarcely to be distinguished from the surrounding membrane. There is an oval epiglottis, with two little folds of membrane at its root, which are susceptible of vibration.

The *long-tailed phalangers* of Cook have a membrane, which serves at once for a vocal ligament and the edge of the glottis; between which, and the cricoid cartilage, there is a groove which might be considered as a ventricle in an unusual situation. This ventricle has also been observed in the glottis of the *ornithorhynchus*, in which animal it is very deep. Both the *ornithorhynchus* and *echidna* have the edge of the glottis formed by the arytenoid cartilage, and a single vocal ligament. There is no ventricle in the glottis of the *echidna*.

In the *didelphis orientalis* there is no distinct ligament, and the epiglottis is deeply notched.

In the *saligrade* mammalia, Cuvier has described two different kinds of structure in the organs of voice. In the one, of which he gives the *porcupine* as an instance, the *cordæ vocales* and ventricles are not found, or scarcely discernible: in the other, which seems to belong to the great majority of the

the

MAMMALIA.

the order, the vocal ligaments are distinct, and the ventricles often deep. The glottis in the *hare* and *rabbit* is peculiar. It wants the superior ligament, and the cuneiform cartilages: nevertheless, the arytenoid cartilages are pyramidal, and afford attachment to two cordæ vocales, which are very free and thin edged, and are separated from the base of the epiglottis by a deep narrow groove. Between their commissure, at the base of the epiglottis, there are two little cartilaginous tubercles projecting inwards. They do not give any attachment to the anterior extremities of the vocal ligaments, which are fixed externally to them.

Amongst the *edentata*, Cuvier describes the organs of voice as differing in each genus. In the *Cape ant-eater* (*oryzæropus*), the cordæ vocales form the edge of the glottis; there is but a slight groove in place of the ventricle. In the *armadillo* the larynx is smooth internally, and the epiglottis is in two lobes.

The *tardigrade* quadrupeds have a singularly formed larynx. The free edges of the cordæ vocales are the inferior ones; they hang down against the inner side of the cricoid cartilage, like triangular valves. There are no ventricles or anterior ligaments.

Amongst the *many-hoofed* tribe of quadrupeds, the *elephant* has a simply formed larynx. The inferior ligaments of the glottis or cordæ vocales are prominent, and sharp edged. They ascend in proceeding to their anterior attachment much more than is usual. The ventricles are mere grooves.

In the *pig*, the direction of the cordæ vocales is peculiar: they descend anteriorly. They are long and sharp edged; and capable of being rendered extremely tense by the actions of the larynx, which enable this animal to utter the shrill cry it is so remarkable for. The ventricle opens posteriorly into an oblong sinus, that ascends between the internal membrane and the thyroid cartilage. The magnitude of this sinus has been over-rated by some anatomists. Its real size, according to Cuvier's observations and our own, is about sufficient to admit the end of the little finger. It is this cavity which enables the *pig* to produce the *grunting* sound, the cordæ vocales being at the same time in the relaxed state.

In the *cloven-hoofed* quadrupeds, a superior angle of the arytenoid cartilages bends backwards, and makes the two-thirds of the end of the glottis; and an inferior angle of the arytenoid bends forwards, and gives attachment to the cordæ vocales. This last has the anterior part more or less free, sharp, and thin, according to the species, but its posterior edge is blunt, and continued into the membrane lining the rest of the glottis. The anterior ligaments are not found, and the place of the ventricle is supplied by the furrow arising from the projection of the cordæ vocales. There are no cuneiform cartilages in this tribe. The thyroid cartilage swells out anteriorly, where the cordæ vocales are attached in the *fallow deer*, and still more in the *cervine antelope*, in which the projection is nearly pyramidal. The swelling under the throat in the *antelope gutturosa*, is occasioned by this enlargement of the thyroid cartilage.

There is a membranous sac in the front of the thyroid cartilage in several of the *antelope* genus and the *rein deer*. The opening into it is at the root of the epiglottis. The sac of the *rein deer* is very large, extending under the neck, as in the *mandril* (*simia maimon*).

Cuvier has given a full description of the organs of voice in the *solid-hoofed* quadrupeds, in which he has corrected many errors in the account of the larynx of the *horse* and *ass* by Herissant. The chief peculiarities of the vocal organs of these animals, consist in the sacs connected with the larynx. There are three of these: one is situated anteriorly,

under the vault formed by the anterior boundary of the thyroid cartilage: the opening into it is under the root of the epiglottis. The two others are oblong sinuses contained between the lateral parietes of the glottis and the thyroid cartilage, and covered, in a great measure, by the thyro-arytenoidæ muscles, by which they are compressed. There is no anterior ligament of the glottis, nor any ventricle, properly speaking; but above the cordæ vocales, on each side, there is a foramen which leads into the lateral sac.

In the *horse* the apertures of the lateral sacs are long and wide, and bear some resemblance to the usual ventricles of the glottis. The opening into the anterior cavity is very wide in the *horse*, in which also this cavity is a shallow depression. On the contrary, in the *ass*, the opening into each of the three sacs is a small and round hole, and the anterior sac is a real bag of considerable size.

Cuvier states that the *mule*, which is generated by the *male ass* and the *mare*, has the openings into the laryngeal sacs wide, and the structure of the organs of voice altogether approaching that found in the *horse*, and he concludes that the account published by Herissant was taken from the dissection of the offspring of the *stallion* and the *female ass*. Blumenbach has, however, followed many other anatomists in attributing similar organs of voice to the *common mule* and the *ass*. We are not enabled to decide the point, not having dissected these organs in the *mule*.

Cuvier further adds, that in the *horse* and the *mule* there is at the commissure of the two cordæ vocales a slight fold of the membrane, which is not visible in the *ass*. The size of this fold has been greatly exaggerated by Herissant; he has also attributed to it important offices which it does not seem to perform.

The peculiar sound called a *bray*, is uttered by the *ass* in consequence of the extent of the laryngeal sacs, and their being so much separated from the cavity of the larynx, by thus having small apertures. The *bray* seems to be a compound discordant sound, produced from the resonance of different sized cavities.

Cuvier found in the *couagga* the larynx organized as in the *horse*, except that the membrane extending from one cordæ vocalis to the other did not exist.

The larynx is very peculiarly formed in the *cetacea*. The arytenoid cartilages and the epiglottis have the figure of very elongated triangles. These three cartilages are united to each other by the membrane of the glottis, and have a degree and kind of motion somewhat similar to that of the parts about the mouth of a fish. The top of the larynx, which is composed of these three cartilages, has a pyramidal figure, and is inserted into the common origin of the posterior nares. It is retained in that situation by the circular muscles of the fleshy tube which forms the common passage to the nares. The usual office of the epiglottis is, therefore, lost in *cetacea*, and instead of making an operculum to the rima of the glottis, it enters into the composition of that aperture, which is thence rendered widest in the transverse direction, and resembles very much, in appearance, the mouth of a fish. The advantage of having the air-tube immediately connected with the nasal passages in the *whale* kind, must be obvious. These animals catch their prey by swimming with their mouths open, and below the surface of the sea, at which times, the water and small fish are carried through the fauces on each side of the pyramid formed by the larynx. When, however, the latter is withdrawn from the posterior nares, in order to eject the water through the spiracles, the rima glottidis is shut; but rather by the edges being closely applied to each other, than by being covered by the epiglottis.

The interior part of the larynx in *cetacea*, exhibits no true cordæ vocales or ventricles. The membrane, at the anterior part of the cavity, forms some very irregular folds, or rather a corded appearance, resembling, in a degree, the internal surfaces of the heart. Cuvier says, he only perceived some longitudinal rugæ. The inequalities on the interior part of the larynx, in these animals, do not, however, appear capable of vibrating sufficiently to produce any voice; or if the *whale tribe* do utter any sound, it must, we conceive, be a kind of *hiss*, occasioned by the forcible emission of the air through the aperture of the glottis.

In *Plates XIV. and XV. of the Anatomy of Mammalia*, the figures are found which illustrate the structure of the organs of voice.

In *Plate XIV. fig. 8* represents the entire larynx and sac of the *mandril* (*simia maimon*), as it appears when dissected out: *a*, the root of the tongue left with the larynx; *b*, the os hyoides; *c* is the laryngeal sac distended with air; *d*, the trachea seen beyond it. *Fig. 9*, of the same plate, shews the larynx opened from behind; and the hole which leads into the laryngeal sac, as it usually appears in those monkeys that have these dilatations connected with the organ of voice: *a*, the epiglottis; *b*, the foramen at its base, opening into the laryngeal sac, which has been cut off in this preparation; *c, c*, the cordæ vocales; *d, d*, the two ventricles.

In *Plate XV. fig. 1* is a view of the larynx, and bony sac attached to it, divided longitudinally to shew their internal formation in the *howling baboon*. This figure is copied from one of Vic d'Azir's, and of course agrees with his description of the organs of voice in this animal: *a* is the tongue, divided lengthwise through its middle; *b, c*, pharynx and œsophagus laid open; *c*, the ligament between the bony sac and the thyroid cartilage; *g, s, o, p, t*, larynx and trachea laid open; *d*, epiglottis; *f, g, h*, bony sac laid open; *i, k, l*, the course of the tube leading from the sac to the larynx; *m*, a projection of the thyroid cartilage dividing the tube into two; *p*, the corda vocalis of that side; *o*, the ventricle of the glottis. *Fig. 2* exhibits a view of the larynx, similar to the last, in the *simia paniscus*: *a*, the tongue; *b*, the epiglottis; *c*, the thyroid cartilage; *d*, the arytenoid cartilage; *f*, the ventricle of the glottis; *g, g*, cricoid cartilage; *h*, the sac, which in this animal is placed at the membranous part of the beginning of the trachea: it is laid open. *Fig. 3* represents the interior of the larynx in the *cat*: *a*, the epiglottis; *b, b*, the cordæ vocales; *c, c*, the two membranes, which are thought to produce, by their vibration, the *purring* sound made by this animal. *Fig. 4* shews the internal parts in the larynx of the *pig*: *a, a*, the ligaments of the glottis seen descending towards the thyroid cartilage; *b, b*, the ventricles; *c, c*, their opening into the sinuses connected with them. *Fig. 5* is the larynx of the *porpoise* laid open behind: *a*, the epiglottis; *b, b*, the arytenoid cartilages; *c*, the wrinkled or corded appearance, which seems to correspond with the cordæ vocales and ventricles of other mammalia. *Fig. 6* gives a view of the interior of the larynx in the *horse*, to shew the opening into the three laryngeal sacs: *a*, the aperture of the anterior sac; *b, b*, the openings of the lateral cavities; *c*, the transverse membrane found in the *horse* at the commissure of the cordæ vocales. *Fig. 7* is a lateral view of the larynx and sacs in the *ass*, with the parts laid open: *a*, the anterior sac, which has a considerable capacity, although so small an opening into the larynx; *b*, the aperture of the lateral sac on one side; *c*, part of the sac of the other side, which is not removed in the dissection.

MAMMARIA, in *Natural History*, a genus of the class Vermes, and order Mollusca. The generic character is,

body smooth; without cirri or rays; aperture single. There are three

Species.

MAMMILLA. In this the body is conic, ventricose, white: it is found in the North seas.

VARIA. Body ovate, varied with white and purple: inhabits the northern ocean.

GLOBULUS. Body globular, cinereous, and not fixed. Found on the Greenland shores, among the roots of fuci. The body is very simple, soft, smooth, gelatinous, with a thin skin about the eighth of an inch in diameter.

MAMMARY, in *Anatomy*, an epithet applied to various parts belonging to, or connected with, the breast. The internal mammary artery is a branch of the subclavian situated within the chest. (See ARTERY.) There is a vein corresponding to it. The mammary gland is the organ secreting the milk. See BREAST.

MAMMEA, in *Botany*, one of Plumier's genera, so called from its vernacular appellation in the West Indies, *Mamei*. Linnæus admitted the name, because of its affinity to *mamma*, a breast, alluding to the shape of the fruit. Schreber and Jacquin place this genus in the class *Polygamia*, but we refer it, after Linnæus and Willdenow, to *Polyandria*. Plum. Nov. Gen. 44. t. 4. Linn. Gen. 265. Schreb. 729. Willd. Sp. Pl. v. 2. 1157. Mart. Mill. Dict. v. 3. Ant. Hort. Kew. ed. 2. v. 3. 297. Jacq. Amer. 268. Juss. 257. Lamarck. Illustr. t. 458.—Class and order, *Polyandria Monogynia*. Nat. Ord. *Guttiferæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, cloven into two, roundish, concave, leathery, coloured, widely spreading, deciduous segments. Cor. Petals four, roundish, concave, widely spreading, somewhat leathery, longer than the calyx. Stam. Filaments numerous, brittle-shaped, erect, very short, inserted into the receptacle; anthers oblong, obtuse, erect. Pist. Germen roundish, depressed; style cylindrical, erect, longer than the stamens, permanent; stigma capitate, convex. Peric. Fruit spherical, fleshy, of one cell, very large, pointed with a part of the style, its rind leathery. Seeds four, nearly ovate, rough, separated from each other by the pulp.

Ess. Ch. Corolla of four petals. Calyx of two leaves. Fruit very large, inferior, with four seeds.

Obs. The flowers of this genus, instead of being always perfect, are occasionally found to be only male ones on the same or on a different plant. This was observed by Jacquin, and Browne in his history of Jamaica takes occasion from this circumstance to make different species of such as have perfect, and such as have only male flowers; Swartz also observes that the former trees are larger and loftier than the latter.

1. *M. americana*. American Mamee apple. Linn. Sp. Pl. 731. Plum. Ic. t. 170.—A native of Jamaica, Hispaniola, and the Caribbee Islands. A tall, handsome tree, with a thick spreading, elegant head. Branches quadrangular when young. Leaves opposite, on short footstalks, oval, or obovate, entire, blunt, very smooth and shining, leathery, firm, from five to eight inches in length. Flower-stalks short, scattered over the stouter branches, bearing a solitary, fragrant, white flower an inch and half in diameter. The calyx is occasionally tritid, and the corolla five or six-petalled. Fruit slightly angular, generally having one or two abortive seeds, from three to seven inches in diameter; its rind double, the outer leathery, tough, brownish; the inner thin, yellow, adhering closely to the pulp which is firm, bright yellow, of a pleasant, though singular flavour, and a sweet aromatic smell. The skin and seeds are bitter

bitter and resinous. Jacquin tells us that the Mammee fruit is eaten raw and alone, or cut into slices with wine and fugar, or preserved in fyrup. In Martinico, the flowers are distilled with spirits, making a liquor which is called *Eau-Creole*. The French term this plant *Abricot-Jawage*, the yellowness of its pulp resembling that of an Apricot. Browne informs us that this is one of the largest trees in Jamaica, that it abounds with a resinous gum, and is esteemed one of the best timber-trees. From Miller we learn that it rises to the height of sixty or seventy feet, and that its fruit, which is of a yellowish-green colour, and highly esteemed, is commonly to be purchased in the markets of the Spanish West Indies.

This tree having a long downright tap-root, is of course very difficult to transplant, so that the best mode of propagating it is by setting the stones or feeds, as fresh as possible, in pots filled with light earth, and then to plunge them into a hot-bed of bark.

M. asiatica of Linnæus Sp. Pl. 731, is now called BARRINGTONIA; see that article in this work, and in Mart. Mill. Dict. v. 1.

Willdenow describes another species which he calls *humilis*, the fruit of which contains only three seeds; but he says that Vahl takes it to be nothing else than *Rheedia lateriflora* of Linnæus.

MAMMEA, in *Gardening*, contains plants of the evergreen exotic tree kind, of which the species mostly cultivated is, the American mammee, (*M. americana*.)

Method of Culture.—This tree may be increased from seeds procured from America, which should be sown in the early spring; in pots filled with light fresh mould, plunging them in a bark hot-bed, keeping the mould moist by occasional watering, when they will soon come up. The young plants should be often watered in dry weather. When they have attained some growth, they should be removed, with earth about them, into other pots a little larger, being replaced in the hot-bed, till fresh rooted, filling up the pots with fresh mould; due shade, air, and water being given. In the autumn they should be removed into the stove, where they must be kept, being shifted into other pots in the following spring; having regard not to over-pot them.

And they may also be raised by placing the stones of the fruit under the pots upon the tan, more expeditiously than when planted in the mould of the pots.

These plants afford a fine variety among others of the stove kind.

MAMMEE BAY, in *Geography*, a bay on the north coast of the island of Jamaica. N. lat. 18° 58'. W. long. 77°.

MAMMILLARIS PROCESSUS, in *Anatomy*, the same as the maltoid process. This term, mammillary, has been sometimes applied to the uriferous substance of the kidney. See KIDNEY.

MAMMOTH'S TEETH, or *Mammot Bones* and *Mammot's Horns*, in *Natural History*, names given by travellers and other writers to certain fossil teeth, and other bones, found in Russia and some other parts of the world, and that usually at great depth in the earth. The Russians and other people give them this name, supposing them to have belonged to an animal, which they describe as being of a monstrous size, and living in caverns under ground. But the true account of them is, that they are in reality the teeth and other bones of an animal now unknown, there being no such beast as these people describe. The mammoth of America, whose enormous bones are found particularly near the salt springs upon the Ohio, though armed with tusks of ivory, has been supposed to be even five or six times larger

than the elephant; but the bones are probably the same with those of the supposed elephant found in Siberia. In Siberia the bones of the mammoth are thrown ashore from the Frozen ocean; and it is probable that these and other similar remains may have been driven by currents from very distant parts of the globe, and deposited on the banks of rivers by the tide, when a great part of the north of Siberia was covered by the sea. The tusks of the mammoth are equal to elephants' teeth in whiteness and beauty, but very different in their shape, being all bent spirally, forming about one round and a half; and eight feet form their greatest length. See ELEPHANT'S BONES, IVORY, &c.

MAMOOJOO, in *Geography*, a town on the west coast of the island of Celebes. S. lat. 2° 19'. E. long. 119° 12'.

MAMORA. See MAHMORA.

MAMOS, a town of South America, in the audience of Quito; 110 miles E.N.E. of Archidona.

MAMOSA, LA, a town of Naples, in Basilicata; 19 miles S.W. of Turin.

MAMOUTKAN, a town of Asiatic Turkey, in the province of Caramania; 12 miles S.E. of Erekli.

MAMPATA, in *Botany*, according to Jussieu, is the Senegal name of a tree, gathered there by Adanson, which the former conceives to be of the same genus with Aublet's *Parinari*, Aubl. Guian. t. 204—206, the *Petrocarya* of Schreber, though its nut is less deeply furrowed, and the stemens appear to be fifteen instead of fourteen. The germen, moreover, is laterally attached to the calyx. See PETROCARYA and NEOU.

MAMTRASNA, in *Geography*, a mountain of Ireland, in the county of Galway; 15 miles S. of Castlebar.

MAMUD, an island in the Sooloo Archipelago. N. lat. 6° 4'. E. long. 121° 42'.

MAMUL, a town of Walachia; 51 miles N.E. of Krajova.

MAMUN, a town of Africa, in the country of Sugulmeffa; 25 miles S.E. of Sugulmeffa.

MAN. To write a complete history of man, it is necessary that we should describe both the individual and the species: that we should, with reference to the former, relate the phenomena of his first production, examine his anatomical structure, his bodily and intellectual functions, and his diseases, and pursue his progress from the time of birth to the grave: in respect to the latter, it would be necessary to point out the circumstances that distinguish him from other animals, to delineate the physical and moral characters of the people inhabiting the different portions of the globe, and trace their progress from the first rudiments of civil society to the state at which they are now arrived. (See on the latter subject, Condorcet *Tableau du Progrès de l'Esprit humain*; Iselin, *Geschichte der menschheit*; Ferguson's *History of Civil Society*; Adelung *versuch einer Geschichte der Cultur des menschlichen Geschlechts*, &c.) To treat the subject in this way would demand a familiar acquaintance with almost the whole circle of human knowledge, and a combination of the most opposite pursuits and talents; of the knowledge of nature possessed by a Buffon, a Cuvier, or a Blumenbach; the insight into the operations of the human mind and passions of a Hume, a Rousseau, and a Condorcet; and a knowledge of history and antiquities in their most extensive sense: a cyclopædia would be necessary, rather than a single article. This extensive labour, which could not be properly executed by any individual, is divided into several subordinate branches. The anatomist and physiologist unfold the structure and functions of the body; the surgeon and physician describe its diseases; and the metaphysician and moralist employ themselves with the functions

that constitute the mind, and with the moral sentiments. We refer, therefore, to the different articles of the Cyclopædia on these subjects; giving only, what could not be entirely omitted in a view of the history of man, a short general sketch of his passage through the various periods of his existence. Man in society, his progress in the various countries and ages of the world, his multiplication, &c. &c. are the province of the historian and political economist. Our object, in the following article, is the description of the species. We shall speak, in the first place, of the situations which man occupies on the globe, of his food, intoxicating drinks, dwellings, and dress; we shall endeavour to explain the distinctions, more particularly in bodily structure, between man and animals; to describe the principal differences between the various races of mankind, and to consider the causes by which these have been accounted for. This, indeed, is rather what our limits and the confined knowledge of an individual restrain us to, than a discussion of all the points which the history of man should involve. We think it should contain, moreover, a consideration of the original abode and distribution of the species, of the varieties of intellectual power, and moral dispositions. The remarkable manners and customs, the employments and pleasures, the notions of decency and elegance, honour and shame, the religious opinions, forms of government and laws, particularly among uncivilized nations, are very interesting subjects, when considered in general, but are not included in the labours of the historian or moralist. The education of children, and treatment of women, in all parts of the world; the various degrees of cultivation; the opinions of savage people concerning the most important works and phenomena of nature; the origin of the most necessary sciences, as arithmetic, measure of time, and medicine, are not less interesting than important topics, which are not considered at all, as the historian, the geographer, the moralist, and the man of science, occupied with other pursuits, consider them, each, as not belonging to his department. These, together with the subjects of the present article, would constitute a peculiar science, or branch of science, under the name of the history of man, which, in point of instruction or entertainment, would not be inferior to the narratives of intrigue and treachery, of war, conquest, and desolation, that compose general history.

The natural history of man is yet in its infancy; inasmuch, that we cannot pretend to give any thing like a complete view of the subject. The description and arrangement of the various productions of the globe have occupied numerous observers in all ages of the world. Every plant and every insect has had its historian, and has been described with minute accuracy, while the human subject has been comparatively neglected. In a very voluminous work on the history of the animal kingdom, now publishing in this country, ("General Zoology, or Systematic Natural History,") man is entirely omitted. Does the learned author deem him more or less than an animal? Whether we investigate the physical or the moral nature of man, we recognize, at every step, the limited extent of our knowledge, and are obliged to confess that ignorance, which a Rousseau and a Buffon have not been ashamed to avow. "The most useful and the least successfully cultivated of all human knowledge, is that of man; and the inscription on the temple of Delphi contained a more important and difficult precept, than all the books of the moralists." (Discours sur l'Inégalité; preface.) The immortal historian of nature gives his testimony to the same effect. "Quelque intérêt que nous ayons a nous connaître nous-mêmes, je ne fais si nous ne connaissons pas mieux tout ce qui n'est pas

nous." (De la Nature de l'Homme.) It is only of late, and principally through the excellent writings of Blumenbach, that the natural history of man has begun to receive its due share of attention; and we shall venture to assert, that, whether we regard the intrinsic importance of the questions that arise, and their relation to the affinities, migrations, and history of nations, or advert merely to the pleasure of the research, no subject will be found more worthy of minute investigation.

I. History of the Individual.

The sources from which the history of man must be derived, are human and comparative anatomy; the natural history of organized beings in general, and of the animal kingdom in particular. These branches of knowledge are of the greatest importance: comparative anatomy, and the analogies afforded by the natural history of animals, will often afford us more assistance than the most learned labours of the historian. We must not be content with noting the more striking varieties of the human species, but must investigate all the intermediate gradations. The best sources of information in books, particularly of travels, must not be employed too indiscriminately: a disposition to doubt, and a critical estimation and balancing of authorities, are essentially necessary to prevent us from being led into error by the ignorance or credulity, the inaccuracy or the pre-conceived notions of the writers. Certain parts of physical science are connected with the subject; as an acquaintance with the face of the globe, climates, &c. History, in the common acceptance of the word; that of the human race in its early periods; of particular people and their changes of situation, when they have emerged from the thick cloud that covers the first ages of the world, so as to admit of being distinctly traced, will very considerably aid our investigations. The subject still labours under difficulties, from our imperfect knowledge of the habits and anatomy of those mixtures which most nearly resemble man; from the impenetrable darkness that involves the infancy of the species; the uncertainty of the ancient geography in general, and of the modern geography of many remote regions; and our defective acquaintance with the wild races.

Progress of Man through the various Stages of his Existence.

—The differences in structure and functions between the male and female are explained in the article GENERATION, under the head of *sexual distinctions*; the mode in which reproduction is effected in the human subject, as well as the different theories concerning this highly interesting and important, but obscure function, are considered in the same article. Under EMBRYO, we have described the formation and development of the new being, and the circumstances in which its organization and mode of existence differ from those of the individual after birth.

Fetal Existence.—The precise period at which the future man begins to exist, and the form under which his rudiment appears, are not yet known. For many days after conception, the cavity of the uterus contains nothing in which we can conceive organization to reside: the lord of the creation is lost in a drop of mucus. A soft substance, not resisting the slightest touch, and unfolding to our observation no arrangement of different parts, assumes a roundish shape about the second week after a fruitful coition, and may be regarded as the first appearance of the ovum: a fœtus cannot be seen in this till towards the end of the third week. Possessing at this time the most simple kind of vitality, very similar indeed to that of the vegetable, it has true blood about the fourth week. Now the motion of the heart is visible; in some very rare instances (Blumenbach, Instit.

Physiol.

Physiol. § 641.) it has been seen in the human embryo, but it was observed even by Aristotle in the incubated chick: its motion could not fail to be noticed from the contrast it afforded to the quiescence of the other parts, and hence the expression of *punctum fulgens*. The formation of bone commences at the seventh or eighth week: bony nuclei are first visible in the clavicles, ribs, vertebrae, the larger cylindrical bones of the extremities, the lower jaw, and some other bones of the face: a most delicate bony network is developed at the same time in the flat bones of the cranium, as the frontal and occipital, later in the parietal, &c.

The nearer the embryo, and indeed the animal both before and after birth, is to the epocha of its first production, the more rapid is its growth. That the first germ, when hidden in the ovum, must be exceedingly small, is clear, because it escapes our closest observation, even when assisted by the microscope: from this minuteness it increases in nine months to the weight of six or eight pounds. It grows in the first month to 300,000 times its first size; in the second month to 48 times; and in each of the remaining months of utero-gestation, one with the other, to 15 times. At the end of three years the child has grown from 105 to 281 ounces, or nearly in the ratio of five to fourteen; and in the 22 following, from 281 to 2250 ounces, which is an increase of about eight times.

About the middle of pregnancy, motions of the child are first perceived by the mother; in common language it is said to *quicken*, and the popular notion is that it receives life at this time. The judicial questions concerning abortion, and the execution of pregnant criminals, render it important that right views should be entertained on this point. By the Roman law the punishment of death was inflicted, when a formed and animated foetus perished by abortion intentionally produced; and it was held that the foetus possessed animation on the fortieth day. In this country a condemned criminal is respited, if she is found to be *quick* with child. It seems to be implied in both cases, and such we believe to be the general opinion, that the child is not alive until a certain period of gestation. This is most erroneous, physiologically: vital processes, as an exceedingly rapid growth and development of parts, are carried on with great activity from the earliest time, at which the germ can be discerned, and the heart actually beats at the fourth week. Hence, if abortion be procured at the end of a month, or a woman be executed at the same time, a child is destroyed in either case, just as much as if these things happen after the ordinary period of quickening. Our physiological views of fetal existence lead us to suppose that the creature in utero has no sensations, and is unconscious of its own life: its destruction, therefore, cannot be charged with the infliction of cruelty on a sentient being.

Divines are much interested in a point allied to this; namely, at what time the new being has a soul. Very nice questions have been raised in the Romish church concerning the propriety of baptizing, administering the sacrament of extreme unction, and performing the burial service at particular ages; and these must be equally interesting topics to all, as such ceremonies are ordained for the benefit of those animals only which have souls. Physiologists, in general, have not acted very fairly in refusing their assistance towards elucidating so important a subject. "De his mysteriis," says Haller, "et de animæ humanæ origine, perinde cum Galeno abstinere pronuntiare." He adds, however, immediately after, that he supposes the foetus to have a soul, when it performs spontaneous motion. (Lib. 29, sect. 3, § 21.) To ascertain the meaning of the word soul, is a very important preliminary in settling our notions on this

subject. We are fully convinced that the foetus has no sensations, and consequently can have no will, nor any intellectual functions (see EMBRYO): this is equivalent to saying that it has no soul. For an account of the different opinions concerning the nature and faculties of the soul, see SOUL.

Fat and bile are formed about the middle of utero-gestation. In the remaining part of the time, the hair of the head and the nails appear; the external ear becomes firm and elastic; and the testes descend in the male.

The foetus is lodged in the uterus, until its organization is arrived at such a degree of development, as will enable it to assume independent existence. During its residence in this organ, it may be regarded as a part of the body of the mother: although it has brain, organs of sense and voice, these are yet inactive, and do not give rise to any relations between it and surrounding objects: its organs of digestion, secretion, and locomotion, are equally inert, and calculated, like the former, for the succeeding stage of existence. It has all the organs that enable it to exist by itself, although their functions are not necessary while it continues in the womb of the mother. (See MONSTER.) The chief peculiarities of the fetal state are, the simplicity of its life, consisting of little more than the function of nutrition, and the inactivity of almost all the important organs: its confinement, surrounded by the fluid of the amnios, in the uterus, where no external impressions can reach it, and the exercise of the moving powers is impracticable, even if volition could take place: the connection with the mother through the umbilical chord and placenta (see EMBRYO): the uniform colour of the blood in all the vessels, and the communications between the two sides of the heart. (See HEART and CIRCULATION.) As respiration has never taken place, the lungs sink in water. (See LUNGS.) The cæcum is very different from that of the adult, and the large intestine, in general, is distended with a peculiar dark green semi-fluid substance, called meconium. (See INTESTINE.) The urachus, the membrana pupillaris, and the descent of the testes, are important peculiarities in the fetal state, as nothing like a rational conjecture concerning their use or purpose can be formed. (See the description of the bladder, in the article KIDNEY; of the iris, in EYE; and of the testis, in GENERATION.) Three organs, of a tissue approaching more nearly to that of glands than to any other, appear by their superior size in the unborn child to belong particularly to its economy, although here, as in the parts just noticed, we are entirely ignorant of the uses to which they are subservient. The two former are not only much larger in the foetus than in the adult, but they also contain a considerable quantity of fluid in their texture; the thymus, although as large as the heart in the foetus, is entirely lost in the adult: the two other organs are much smaller comparatively after birth. See THYMUS, LARYNX, and KIDNEY.

Birth.—Towards the end of the tenth lunar month, when the child has arrived at a weight varying from four to eleven pounds, though generally between five and eight, and is from eighteen to twenty-one inches long, parturition takes place; several very important changes occur in the animal economy, and a state of being, altogether new, commences. "Nothing," says Buffon, "exhibits such a striking picture of weakness, of pain, and of misery, as the condition of an infant immediately after birth. Incapable of employing its organs or its senses, the infant requires every kind of assistance; it is more helpless than the young of any other animal; its uncertain life seems every moment to vibrate on the borders of death. It can neither move nor

support its body; it has hardly strength enough to exist, and to announce, by groans, the pain which it suffers; as if nature intended to apprise the little innocent, that it is born to misery, and that it is to be ranked among human creatures only to partake of their infirmities and afflictions." *History of Man, sect. ii.*

The navel-string being tied and divided, the connection between the mother and child is separated. In animals, this cord is severed by the teeth; if it were not tied in the human subject, fatal hæmorrhage would ensue. The child, from the warm medium of the amniotic fluid, is introduced into a new and more stimulating element, the air, and draws it into his lungs: thus respiration begins, and produces changes in the blood, which seem to make up for the loss of the placental circulation. A healthy and strong child generally cries as soon as it comes out of the vagina, and inspiration is necessary to this action. We usually wash the body with warm water and soap, in order to remove the greasy substance that covers the skin, and are very careful to keep the child warm; but there are whole nations, inhabiting climates colder than our's, where the infants are plunged into cold water as soon as they are born, without receiving the slightest injury. The desire for food seems to be coeval with the commencement of the new existence: sucking is performed at once in a perfect manner, as soon as the mouth is brought to the nipple.

Within a few hours after birth, meconium and urine are discharged. The infant sleeps much, and seems to awake only for the purpose of taking food: the gratification of the latter want, and sleep, are the great employments of the first months.

Infancy.—As we remember nothing of what passes at this early period of our existence, we cannot discover the feelings produced by the first impressions of the air; but the cries uttered immediately after birth seem to indicate that the action of the atmosphere causes painful impressions. The senses at first act very imperfectly; the newly born creatures have a stupid appearance, and give hardly any proof that their organs of sense act. The eyes are fixed and dull, and have not the motions which accompany distinct vision; yet they feel the impression of light, and the pupil contracts or dilates in proportion to its quantity. When any thing is suddenly brought near to the eye, neither the lids nor the head are moved. The other senses are in an equally imperfect state. All the other parts of the body are extremely feeble, and their motions awkward and ill directed. The thighs and legs are bent, from the habit contracted while in the womb of the mother; there is not strength enough to seize any thing with the hands; if abandoned in this condition, the child would remain on its back, without being able to turn to one side or the other. See LIFE.

The pulsation of the brain is felt at the fontanells.

Besides the commencement of the functions that connect us to the external world, as well as those of the digestive apparatus, and the modifications of the circulating organs consequent on the ligation of the chord, and the beginning of respiration, various alterations in the external habit of the body are discernible after parturition. The downy covering of the skin gradually disappears, the wrinkles are obliterated, the nates are developed, and hide the opening of the anus.

A newly born infant discovers pain by its cries; but it has no expression indicating pleasure. It smiles about the sixth or seventh week, and it begins to weep about the same time; for its former cries were not accompanied with tears.

Newly born children sleep much, but only for short periods; they require very frequent nourishment, and express

this want by crying, which generally terminates their sleep. This indication should always be carefully attended to. Nothing is required in addition to what nature has provided in the mother's milk; no substitute is equal to this, though the milk of other animals may be employed in cases of necessity: the teat of the animal may be substituted for that of the mother. Buffon says that he has known several peafants, who had no other nurses than ewes; and yet they were equally vigorous as those who had been nursed by their mothers.

As soon as the infant had escaped from the uterus, and enjoyed the liberty of stretching its limbs, it was again condemned, while the use of swaddling clothes prevailed, to a more cruel and unnatural bondage. The head and limbs were fixed, and the whole body so laced and fettered, that hardly a joint could be moved. People now begin to find out that the development of the body will be accomplished without this artificial assistance. Perhaps they are hardly yet aware, that the efforts of the little prisoners to disentangle themselves have a more direct tendency to distort their members, than any positions they could assume, if left in the full possession of liberty. Swaddling bands may be compared to the stays worn by young girls, which occasion many more deformities and diseases than they are intended to prevent. The practices of savage nations have been much more rational than those of the civilized; they lay their infants naked in hanging beds of cotton, or cradles lined with fur, in which they are at perfect liberty to move themselves as they are inclined, and provide at the same time very carefully for absorbing the moisture of their discharges. No improvement can be suggested on this plan.

As the child becomes accustomed to external objects, it gradually learns the use of its senses, and loses the apparent stupidity that characterizes it for the first months of existence. It is fond of light, and directs its eyes always to the lightest part of a room; hence the propriety of placing it so that both eyes may receive the light at the same time, and consequently acquire by exercise an equal degree of strength. It is attracted by any shining objects, and endeavours to seize them; when pleased, it smiles; and cries and attempts to resist, when it is hurt or vexed: it recognises individuals, and is frightened by strangers. The organs of the external senses are more perfectly finished, as the external ear, the nostrils, the superciliary arches and eye-brows, &c. At the same time, the mental functions, dependent on the operation of these organs, as attention, perception, memory, the will, &c. are gradually developed: hence dreams are observed in a few months after birth. The bones of the cranium become more firmly united, and the fontanells are gradually closed. Dentition, which begins about the sixth or seventh month, is a most important era in the life of the infant. The process is always painful, and not unfrequently fatal. For the description of the teeth and the history of their development, see CRANIUM: the dangers with which it is accompanied are described under INFANTS, *Diseases of*. This change points out the natural time for weaning: the newly acquired instruments, which injure the nipple of the mother, enable the infant to use firmer food, and thus make it independent of the breast. As conception does not usually take place again, while suckling is continued, mothers, who wish not to have a numerous family, often keep the child at the breast long after this time, although there is no advantage to be derived to the child from the practice.

Ossification goes on with great activity, and confers on all parts of the skeleton that firmness which is essential to the execution of their functions. Bony nuclei are seen in the cartilages, which are afterwards to form the bones of the carpus

carpus and tarsus. The urine contains little or no phosphat of lime, as that substance is all employed in the completion of the bones. Towards the beginning or middle of the second year, they have become strong enough to support the weight of the body, hence the infant at this time begins to learn the use of his feet, and to assume the erect attitude, one of the most remarkable prerogatives of the human species. The smallness of the lower limbs and pelvis, in comparison to the head and upper part of the trunk; the soft state of the bones, as well as the want of power in the muscles, which, like the organs of sense, require the slow education of frequent exercise; and the very complicated exertion necessary to maintain the body erect (see *MUSCLE*, towards the end), postpone the power of going alone to this late period after birth, and render all the motions and positions connected with it very unsteady and unsafe for a still longer time; although animals in general can maintain themselves in their natural attitudes tolerably well from the day of birth. Attempts to make the child assume the erect attitude before the epocha we have mentioned, are dangerous, as the flexible bones, unequal to the burden, give way under it, and thus deformity is produced.

Removal from the mother's breast, and the power of going alone, are two very important steps, and the progress towards independent existence is greatly assisted by another remarkable privilege of the human species, the use of speech, which begins in children of lively minds soon after the first year. The sounds uttered in the caresses of the mother are attended to, and eagerly imitated; and every faculty is strained to the utmost, for the purpose of acquiring the use of an instrument so important towards attaining the gratification of its daily increasing desires, and establishing its communications with surrounding beings. The power of speech, however, like the use of the senses, and of the moving organs, is not possessed perfectly at once; it is the offspring of laborious and repeated efforts. The vowel A (broad) is the most easily pronounced, as it requires only the opening of the mouth, and forcing out the air: the consonants, B, P, and M require the least motion of the organs, and are most easily articulated. The other sounds are formed in proportion as the organs learn their offices. (See *ARTICULATION*.) Some can articulate distinctly, and repeat whatever is said to them, at two years of age, but a longer time is generally necessary.

While the infant is thus slowly advancing in the development of its powers, it is exposed to numerous and destructive diseases, which render its life very precarious for the three first years. (See *INFANTS, Diseases of*.) Half of the children produced die in the first few years of life, and the work of destruction proceeds still more rapidly, when they are crowded together in considerable numbers. Camper informs us, that of 5989 admitted into the establishments for foundlings at Paris, in one year, 4095 died in the first month, and 673 more in the remaining eleven months: only 884 were alive at the end of five years. Ludwig Grundriss der Naturgeschichte der Menschenspecies, p. 293. See *MORTALITY*.

About the seventh year, the deciduous or milk teeth begin to fall out, and a second dentition ensues. Of the thirty-two permanent teeth, which are designed to remain through life, the greatest number have come into the vacancies left by the successive discharge of the temporary ones, by the twelfth year; but the whole set is not complete till the 18th or 20th year.

Childhood, or Adolescence.—In the age of infancy, memory seems to excel the other faculties of the mind, and af-

fords a most commodious instrument for retaining the signs of surrounding objects. It hardly continues in its original strength beyond the fifteenth year. The imagination is developed after it, and begins to predominate when the memory is weakened; its exercise is assisted by the happy memory of this age, which supplies it with materials. The judgment is developed at a later age: children pass rapidly from one object to another, without bestowing the time for accurate comparison and enquiry, which judgment requires.

The nervous system is easily affected in childhood, and grief and joy are excited by slight causes. Much time is passed in sleep.

A considerable stratum of fat covers the body under the integuments, hides the muscles and bones, and bestows a roundness and softness of outline on the whole frame. See *MEMBRANE, Cellular*, and *MUSCLE*, under the head of *development* of those tissues.

The fluids undergo a considerable change: in the fœtus, or in a young child, the urine, fœces, and perspiration are not fetid; the bile is not bitter; all the secretions indeed are mild. But the urine soon acquires its distinguishing smell; the kidneys, which form an agreeable food in the calf, are rejected on account of their strong taste in the bullock; the fœces become more consistent, and have a powerful odour. The food and mode of life are not the causes of these alterations; for the fœces, perspiration, &c. have their strong sensible properties in the adult, even when the diet consists of milk or vegetables.

Puberty.—The great development of the imagination is about the age of puberty, when man is prepared, by various and important changes of his organization, for the exercise of the generative functions. Nature hitherto seems to have had nothing further in view than the growth and preservation of her work. The child enjoys an existence confined to itself, which it cannot communicate; but the principles of life soon multiply beyond what is sufficient for our own being, and enable us to bestow existence on others.

When the mammæ enlarge in the female, the beard shews itself in the male, and the other phenomena of approaching puberty are exhibited in both sexes, as the development of hair on the external organs, &c. the former begins to have the menstrual discharge, which is accompanied, amongst other appearances, with increased lustre of the eyes, redness of the lips, and more sensible properties in the perspiration; the latter secretes true semen, having at the same time a more copious growth of the beard, and a memorable change of the voice into a deeper tone. The latter, for a considerable time, is rough and unequal; after which it becomes more full, articulate, and strong. This change is very conspicuous in boys; but it is less distinguishable in girls, whose voices are naturally more sharp. A very remarkable enlargement of the vocal organ, coeval with puberty, is the source of the alteration just mentioned. There is hardly a sensible difference of size in the larynx, between a child of three, and another of twelve years: there is at least nothing corresponding to the diversity of stature. But at puberty, in the space of a year, the opening of the male glottis is doubled, both in length and breadth. This increase in the female is only in the proportion of seven to five. (Richterand, *Elem. de Physiol.* ed. 3. § 226.) These marks are not always uniform. The beard, for example, does not always appear precisely at the age of puberty: there are even whole nations, who have hardly any beard. On the contrary, there is no country where the age of puberty in women is not distinguished by the enlargement of the breasts. At the same time the sexual instinct is awakened by what we may call the sponta-

neous internal voice of nature, and both sexes, in this spring of their existence, become capable of exercising that important function of all animated beings, the propagation of the species. For the detailed consideration of this subject, see GENERATION. In that article the reader will find a view of the changes occurring in the generative organs at this age, and of the effects, which they exert in the body in general, of menstruation, and of the phenomena observed where unusual organizations exist, constituting what have been often called hermaphrodites.

Virginity, impotence, circumcision, castration, infibulation, &c. are articles so important in the history of man, either on account of the interest attached to some of the subjects, or of the general prevalence of some of the practices, that we should consider it a sacrifice of what is essential to false notions of delicacy, if we passed them over entirely unnoticed. On the subject of virginity, see the account of the hymen, in the description of the vagina, in the article GENERATION, and Buffon's History of Man, sect. 3: respecting *Circumcision* and *Impotence*, see those articles; and concerning the latter, Mr. Hunter's Treatise on the Venereal Disease, pt. iii. ch. 11 and 12. Boys are infibulated by drawing the prepuce forwards, piercing it, and putting through the holes a small cord, which remains until the cicatrix is formed; the cord is then removed, and a ring substituted in its place, which is made of sufficient strength to last as long as the person, who ordered the operation, pleases; and it sometimes remains for life. The Eastern monks, who took the vow of chastity, used to employ a large ring, which rendered a breach of their oath impossible. On this subject hardly any thing can be imagined so ridiculous that it has not been practised by some men, either from motives of passion or of superstition. A similar mode of securing the chastity of the women, which could only be suggested by the rudeness of their manners, has been practised in many barbarous nations. In Ethiopia, and other parts of Africa, in Arabia, Pegu, and other nations of Asia, the inhabitants, immediately after the birth of females, sew up those parts which nature has separated, leaving only a space sufficient for the natural evacuations. As the child grows, the parts gradually adhere, and when the time of marriage arrives, they are again disunited by incision. Instead of thread, the fibres of the asbestos are said to be employed, which is a substance not liable to sudden corruption. Some tribes content themselves with putting a ring through the parts. To this precaution wives as well as girls are subjected, with this difference, that the ring allotted to the latter cannot be removed, but in that of the former there is a lock, of which the husband keeps the key.

The practice of castration is of great antiquity, and has prevailed very extensively. It is employed in Asia, to procure guards for the chastity of the women; in Italy, this infamous, this cruel operation, has for its object only the improvement of the voice. Besides destroying the faculty of propagation, it prevents, or very signally modifies, the changes that usually occur at the time of puberty, and remarkably influences the voice. (See GENERATION and EUNUCHS.) The species of castration varies according to the object in view; the testicles only are removed, when the improvement of the voice is intended. But men, whose minds are possessed with jealousy, would not believe their females safe in the custody of such eunuchs; they employ none but those who have been deprived of all the external organs of generation. Sometimes the texture of the organs has been destroyed by pressing and rubbing them for a long time; but the effect of this process cannot be so securely depended on

as that of removal. Infancy is always preferable for these operations. The amputation of the testicles is not very dangerous: but the more complete removal is often fatal, especially if performed after the age of fifteen; even in the most favourable time, from seven to ten years, there is always great danger. The difficulty of preserving such eunuchs renders them exceedingly precious. Tavernier informs us, that in Turkey and Persia, they bring five or six times the price of the other kind. Chardin observes, that the total amputation is performed pretty safely upon young children, and is exceedingly dangerous after the age of fifteen; that hardly a fourth part escape with life, and that the wound is never cured in less than six weeks. On the other hand, Pietro della Valle asserts, that those who suffer this punishment in Persia for rapes, and other crimes of that nature, recover easily, though advanced in years; and that they apply nothing but ashes to the wound. According to Thevenot, vast numbers of negroes, who are forced by the Turks to submit to this operation, perish, even when it is performed on individuals eight or ten years old.

The arrival of puberty differs according to climate, temperament, way of life, &c. so that no particular age can be set down for its general occurrence. It is earlier in women than in men; the former, in our climate, shew the phenomena of puberty at about the age of fifteen, the latter at that of eighteen. Instances are not very uncommon, of considerable development of the body, with the changes that usually occur at puberty, such as the appearance of the beard, enlargement of the generative organs, secretion of semen, expansion of the breasts, flow of the menses, and formation of hair on the pubes, at a much earlier age than we have mentioned. Besides the instances related in the article GENERATION, a considerable number may be found in Haller's *Elementa Physiologiae*, lib. xxx. sect. i. § 15. *Puer triennis pubescens, virili in pudendis robore, altus 37 uncias.* Journ. de Medecine, 1757. *Puella quatuor annorum mammis conspicua et pube, ut etiam menses pateretur.* Valisneri Op. t. iii. p. 309. *Puer quatuor annorum nubilus, feminarum cupidus, voce gravi, tanto robore, ut libras 50 elevaret.* Journ. de Medecine, 1759. Many other examples are mentioned of children younger than these, who exhibited signs of puberty, such as the growth of the beard, and of the hair on the pubes; and there are numerous instances of others from four years upwards, who have been able to perform all the sexual functions. The termination of the growth of the body in length is fixed a little after this time; the epiphyses of the bones, hitherto distinct from the bodies, now coalesce, and are completely consolidated to them.

Stature of Man.—There is no fixed law, determining invariably the human stature, although there is a standard, as in other species of animals, from which the deviations, independently of disease or accident, are not very considerable in either direction. In the temperate climates of Europe, the height of the human race may be stated at five feet two inches to five feet ten. Schreber gives to the human species a height of from two feet four inches, to five feet eight inches. (*Mammalia*, t. i. p. 27.) Individuals of six feet, and even as high as six feet three and four, are not uncommon in this and other European countries. Occasional instances have been known in various parts of the world, of men reaching the height of seven and eight feet; and ancient as well as modern authors speak of the human stature reaching nine, ten, and even eighteen feet. The latter representations are generally grounded on bones dug out of the earth; these, together with the common propensity to believe and report what is marvellous, and the notion that mankind have undergone

undergone a degeneracy since their first formation, have led to a very common belief that the human stature in general, is at this period less than it was in remote ages. We are warranted in suspecting the accounts of such great elevation above the ordinary stature, in the human species, by observing that nature, within the time of which we have any authentic records, exhibits no such disproportions in other species. We find, too, that the height of these giants is reduced, as we approach to modern times, to what we have opportunities of observing now; so that we may probably affirm, that no sufficiently authenticated example can be adduced of a man higher than eight or nine feet. The large bones on which the notions about giants have been, in many instances, founded, have been discovered, by the accurate examinations of modern science, to belong to extinct species of animals of the elephant and other allied kinds. Of the loose and unphilosophical mode in which these matters have generally been inquired into, we have a specimen in the supposed bones of a barbarian king. Habcot, an anatomist, in a work entitled "Gigantosteologie," describes some huge bones, found near the ruins of the castle of Chaumont in Dauphiny, in a sepulchre, over which was a grey stone, inscribed TEUTOBOCHUS REX. This skeleton, he says, was $25\frac{1}{2}$ feet long, and 10 broad at the shoulders. Riolan, in his "Gigantomachie," disputes the measurements, and affirms that the bones belong to the elephant. In the long controversy which ensued, it is remarkable that no exact description or representations of the bones should have been given. It is very surprising that such a philosopher as Buffon should have figured and described the fossil bones of large animals as remains of human giants, in the 5th vol. of the supplement of his classical work. Among others he has those dug up at Lucerne, in the 16th century, and still preserved there. Blumenbach found these, on the first view, to be elephants' bones. Felix Plater, an excellent physician and anatomist of his time, after carefully examining and measuring these bones, declared that they belonged to a human giant of seventeen feet, and had a drawing made of this skeleton, according to his opinion of its dimensions, which is still preserved in the Jesuits' college at Lucerne. (Blumenbach de Gen. Human. Variet. Nat. p. 251, note.) That men in general were taller in the early ages of the world than at present, or that examples of very tall men were then more frequent than now, has been asserted without any proof. The remains of human bones, and particularly the teeth, which are unchanged in the most ancient urns and burial places, the mummies, and the sarcophagus of the great pyramid of Egypt (Norden's Travels), demonstrate this point clearly; and every fact which we can collect from ancient works of art, from armour, as helmets and breast plates, or from buildings designed for the accommodation of men, concurs in strengthening the proof. Blumenbach has the skull and bones of an old person, taken out of a burial place of the most remote antiquity in Denmark (in antiquissimo tumulo Cimbrico), and corresponding in size to the modern standard. (Ibid. p. 252, note.) That we cannot have degenerated in consequence of the habits of civilized society is clear, because the individuals of nations living in a way so different from us as the Americans, Africans, Southern islanders, &c. do not exceed us in stature. Indeed it has been generally observed that the Americans are shorter than the Europeans.

We frequently meet with examples of individuals below, as well as above the ordinary stature; but when the deviation is considerable, they are rarely well made.

Giants and Dwarfs.—In mentioning individuals who have exceeded the ordinary height, it is necessary to confine ourselves, in order to avoid what may be fabulous or exag-

gerated, to instances in our own times. One of the king of Prussia's gigantic guards, a Swede, was $8\frac{1}{2}$ feet, and a yeoman of the duke John Frederic, at Brunswick-Hanover, was of the same measure. Gilly, who was shewn, measured 8 feet (Swedish). I. H. Hartmann Reichardt of Friedberg, near Frankfort, was 8ft. 3in.: his father was a giant, and his sister a giantess. A female of Stargard, named La Pierre, was 7 ft. (Danish). Ludwig, Grundrifs der Naturgeschichte, &c. p. 150. See also Haller, Elem. Physiol. lib. xxx. sect. 1. § 17. Martin Salmeron, the Mexican giant, is the son of a Mestizo by an Indian woman, and measures 7 ft. $3\frac{1}{2}$ in. (English.) He is very well proportioned. Humboldt's Political Essay, b. ii. ch. 6. Several Irishmen, of from 7 to 8 feet, have been exhibited in this country. Bebe, the dwarf of Stanislaus king of Poland, was 33 in. (French), and well proportioned. His spine became curved as he approached manhood; he grew weak, and died at 23. Buffon, Hist. Naturelle, xv. p. 176.

The Polish nobleman Borwlaski measured 28 Paris inches; was well made, clever, and skilled in languages. He had a brother of 34 in. and a sister of 21. Memoirs of the celebrated dwarf Jos. Borwlaski, &c. Lond. 1788.

A Friesland peasant at 26 years of age had reached 29 Amsterdam inches. C. H. Stöberin of Nürnberg was nearly 3 feet high at 20, well proportioned, and possessed of talents. Her parents, brothers, and sisters, were dwarfs. Lavater Physiognomische Fragmente iv. p. 72.

Of numerous other instances on record, most seem to have been diseased, and particularly rickety, individuals; so that they may rather be classed among pathological phenomena. The men who have considerably exceeded the ordinary standard, have neither possessed those proportions in their form, which we account elegant; nor has their strength by any means corresponded to their size. The head, in these cases, is below the ratio which it should bear to the body, according to what we deduce from men of ordinary stature; hence the brain must be comparatively smaller. It is a general observation that very large men are seldom distinguished by extent or force of mental power. The dwarfs, again, are generally ill made; the head, in particular, is too large. There are very few instances of what we could deem healthy well made men, with all the proper attributes of the race, much below the general standard.

Manhood.—The age of manhood extends from the twenty-first or fifth year to the forty-fifth or fiftieth in the male; it begins and ends rather sooner in the female. At its beginning the growth of the body in length has ended; but it still increases in the other dimensions. All the organs acquire a superior firmness in their texture; the fat and cellular substances are diminished, and the muscles conspicuously enlarged; hence the sharp and hard lines of muscular protuberances are substituted in the place of the rounded and soft outlines of youth. Great muscular strength, vigour, and celerity in the actions of the nervous system, perfect execution of all the bodily functions, in short the highest state of vitality, are the attributes of this age. It is not less characterized by a perfect development of the mental faculties. The judgment in particular is matured, and succeeds to the empire of imagination. Man is now capable of fulfilling all the duties of active life as a citizen and parent. During this long interval, he enjoys the plenitude of his existence. It has been supposed that the body remains in the same condition in this part of life, and hence it has been called by Latin writers, *status hominis*. The function of nutrition supplies whatever is lost in the other processes of the economy, and thus a perpetual change is kept up, although the body appears the same; in this circulation, it has been conceived that

that the whole is changed in the course of a few years. There are no accurate data for calculating the time in which all the particles are renewed; probably, however, this is different in the different tissues. The hair and nails are rapidly renewed; the fat is often increased or removed within a very short time; on the contrary, the marks in the skin produced by puncturing it, and rubbing in various coloured substances, continue through life.

Towards the latter half of the age of manhood, there is a disposition to the deposition of fat over the whole body; indeed such depositions take place at any part of this period, when tranquillity of mind and inactivity of body are joined with copious food. Fat is particularly formed about the abdomen. (See *CORPULENCE*.) As the growth of the frame is finished, and all the functions are carried on with vigour, there is a redundancy of nutrient particles, by which we can account for this occurrence.

Temperaments.—We avail ourselves of this age, in which the characters of the human species, roughly sketched in infancy and youth, are fixed and drawn in indelible colours, in order to delineate the distinctive traits of individuals. We designate by the word temperament the physical and moral differences of men, depending on the various proportions and relations of the part entering into their organization, as well as on the various degrees of energy in certain organs. Thus, the collection of circumstances in the organization or functions of the body, that characterize a number of individuals, constitutes their temperament. Again, each person has a mode of being peculiar to himself, distinguishing his temperament from that of all others, to some of whom he may, however, bear in general a considerable resemblance. These individual temperaments, of which the knowledge is highly important in the practice of medicine, are called *idiosyncrasies*.

The predominance of a particular system of organs modifies the whole economy, impresses striking differences on the results of organization, and exerts no less influence on the moral and intellectual than on the physical powers. This predominance establishes temperament, of which it is the cause and essence.

Since the construction of the body follows the same model in all, it seems strange, at first sight, that each individual should be different from all others, and should possess a character peculiar to himself. Let the number of tissues, or elementary ingredients of the body, be considered; let the number of organs composed by these be taken into the view; let us remember the various vital properties which these possess, and the very numerous functions which they exercise. The original component structure may differ, the organs, which they build up, may vary: the vital forces exist in every possible degree from the highest pitch to the lowest state: the functions are modified by innumerable causes, as climate, food, clothing, way of life, exercise, labour of mind and body, &c. &c. By the various combinations produced by all these differences, individual temperaments or *idiosyncrasies* are sufficiently accounted for. It seems probable, however, that these diversities are in a great measure factitious: all wild animals are alike; the differences between individuals are not considerable in the domesticated races; and there is much greater general resemblance between individual men in savage than in civilized life.

When we ascribe temperaments to differences of organization, we are aware that the truth of the proposition cannot be easily proved, that the anatomist cannot trace in the material fabric the causes of these phenomena, which at present must be regarded rather as characters of the vital functions than of the organization. The operation of

moral causes, too, must greatly obscure this intricate question. Education, acquired habits, situation, and fortune in life, and a long list of causes, have so great an influence on the character and many of the bodily functions, that we are at a great loss in pointing out what ought to be ascribed to original conformation or disposition, and what flows from subsequent agency. We wish, therefore, the following sketch of temperaments which we have borrowed from a French writer (*Richerand, Elements de Physiologie, chap. 11.*) not to be received in a very rigorous sense, as founded on the basis of anatomy, but rather to be regarded as a statement of the views generally entertained on the subject, to the truth of which, anatomically, we would not be considered as pledged.

When the agents of circulation, the heart and blood-vessels, enjoy a predominant activity, the pulse will be strong, frequent, and regular, the skin highly coloured, the physiognomy animated, the forms soft but well expressed, the flesh tolerably firm, the embonpoint moderate, the hair light coloured; the nervous susceptibility lively and rapid, united with quick conception, good memory, and sportive imagination. Such individuals sacrifice freely to Bacchus and Venus, and have their health rarely interrupted by disease. The latter is generally situated in the circulating system, (inflammatory fever, inflammations, active hæmorrhages,) and requires the use of antiphlogistic remedies, particularly of blood-letting. The ancients gave the name of *sanguine* temperament to this disposition of body: they had very correctly observed that it was to be noticed generally in young persons of both sexes, and that its characters are most clearly developed in spring.

The physical traits of this temperament may be seen in the beautiful statues of Antinous, and the Apollo of Belvedere: its moral physiognomy is delineated in the lives of Marc Antony and Alcibiades. Inconstancy is a characteristic attribute of this temperament; great variety is necessary as well as agreeable to the individuals whom it marks. Generous, sensible, and passionate, but inconstant, they are too soon tired after possession, and free themselves from the dominion of Beauty at the very instant when she fancies she has secured them by a durable chain. He, on whom nature has bestowed a sanguine temperament, vainly endeavours to renounce sensual enjoyments, and arrive, by deep meditation, at abstract truth: overpowered by his physical dispositions, he is constantly forced back to the pleasures which he avoids: his mind is better calculated for the brilliant productions of wit, than the sublime conceptions of genius.

When a man of this temperament is forced, by his condition, to undergo labours, which exercise considerably his organs of motion, the muscles acquire a development proportioned to that of the circulating organs, and increase in size; the muscular or athletic temperament, characterized by all the external signs of vigour, is the result. The head is small, the neck powerful, particularly behind, the shoulders broad, the chest wide, the hips firm, and the muscular forms strongly marked. The hands, the feet, the knees, and all the joints not much covered by muscles, appear small; the tendons display themselves under the skin. The susceptibility is not considerable, but when the calm is once disturbed, the greatest resistances are overcome. The *Parthese Hercules* affords a model of the physical attributes of this constitution, and the exploits of this demi-god, as recorded in fabulous antiquity, give us a tolerably just notion of the concomitant moral dispositions. We see him performing his twelve labours without calculation, without reflection, and, as it were by instinct, courageous because he is strong, seeking obstacles that he may overcome them, certain of overwhelming

overwhelming all resistance, but uniting with this vast strength so little address, that he is cheated by all the kings whom he serves, and by all the women whom he loves. It would be difficult to find instances of men who have joined to the physical force of this temperament a considerable degree of intellectual power. To attain excellence in the sciences or fine arts, acute sensibility is necessary, a condition almost incompatible with any marked development of the muscles.

If to an easily excited sensibility we join the power of pursuing one object for a long time; if the pulse is strong, hard, and frequent, the subcutaneous veins prominent, the skin of a brownish tint, inclining towards yellow, the hair black, the flesh firm with the muscles strongly expressed; the passions will be violent, the movements of the soul sudden and impetuous, the character firm and inflexible. Bold in conception, firm and invincible in execution, such men at different epochs have directed the destinies of the world: courageous and active, they have signalized themselves by great exploits, and have commanded the dread or admiration, at all events the homage, of an universe. Such have been Alexander, Julius Cæsar, Brutus, Mahomet, Charles XII., Cromwell, cardinal Richelieu: such is Napoleon the First.

As love in the sanguine, ambition may be regarded the ruling passion of the bilious. Observe that man, who born in an obscure family, vegetates for a long time in the lower ranks of life: great commotions agitate and overturn empires; he is at first a subordinate agent, but, concealing his designs in his own breast, he gradually rises to the sovereign power, and employs, in retaining it, the same address which has aided his elevation. Such is the history of Cromwell, and of all the extraordinary men, whose talents have met with a favourable field for their development. Profound dissimulation and invincible constancy are equally necessary for executing such designs; and these qualities are eminently displayed by men of the bilious temperament, as we may see in the lives of pope Sixtus V. and cardinal Richelieu.

Premature development of the moral faculties is another character of this temperament. When their youth had hardly ended, the men whom we have named conceived and executed designs sufficient to render them illustrious. The ancients called this the *bilious* temperament, as a remarkable development of the liver, and super-abundance of its secretions are united in it to energy of the sanguiferous system. Derangements of the hepatic organs appear in the persons of this temperament as a principal or accessory circumstance of their diseases.

When to the bilious temperament are added a disease of some organ in the abdomen, a derangement in the functions of the nervous system, or a feeble and irregular execution of the vital functions, the skin assumes a deeper colour, the countenance is dark and restless, the abdominal viscera inactive, and the pulse hard. The general uneasiness gives a character to the thoughts; the imagination becomes melancholy, and the character suspicious. The exceedingly numerous varieties of this temperament, which the ancients called *atrabilious* or *melancholic*, and the diversity of circumstances which may produce it, such as hereditary disease, long continued anxiety, excess of study, &c. lead us to the opinion that the melancholic temperament is less to be regarded as a natural and primitive constitution, than as a morbid affection, either hereditary or acquired. The characters of Louis XI. and Tiberius exhibit most faithfully its moral traits, of which distrust and timidity are the most striking. The history of men, who have attained celebrity in the sciences, arts, and literature, makes us acquainted with melan-

cholic individuals of a different character: endued with an exquisite sensibility, enthusiastically fond of the beautiful, and capable of realizing it in their conceptions, living in society in a state of reserve bordering on distrust, analysing most carefully the actions of men, perceiving in matters of sentiment even the most delicate shades, but disposed to unfavourable interpretations, and seeing all objects through the distorting medium of melancholy. It would be extremely difficult to describe this temperament in a general or abstract manner. Although the ground of the picture is the same, the finishing is susceptible of infinite variations: it is better therefore to resort to the history of the illustrious characters in whom it is exhibited. Of these, Tasso, Pascal, Rousseau, Gilbert, and Zimmermann, furnish remarkable illustrations. In the philosopher of Geneva particularly, the melancholic temperament existed in a high degree of energy: numerous passages of his well-known writings, and especially the two last parts of the *Confessions* and the *Reveries du Promeneur solitaire*, give us an instructive picture of its workings.

When the liquids are abundant, they distend and develop the cellular tissue, and give to the whole body a considerable volume. The flesh is soft, the countenance dull, the hair of some light tint, the pulse feeble, the forms rounded and inexpressive, all the vital actions more or less languid, the memory treacherous, and the power of attention weak. The individuals of this temperament, called, by the ancients, *pneumatic*, and which we term *phlegmatic*, have, generally, a strong disposition to idleness, and an invincible repugnance to exercise of the mind as well as of the body: hence, we are not to be surprised that no examples occur among the illustrious men of Plutarch: little suited for business, they have not exercised dominion over their species, nor altered the surface of the globe by negotiation or conquest. Atticus, the friend of Cicero, who lived on good terms with all the parties who successively harassed the Roman republic in the civil wars of Cæsar and Pompey, is an example of this temperament. The circulation is tranquil, the imagination cool, and the passions moderate. From this moderation of the desires arise often the virtues of temperament, as they are called; virtues, by the bye, of which the possessors ought to be the less proud.

The property, by virtue of which we are more or less sensible to impressions on our organs, which is weak in the phlegmatic, very inconsiderable in the muscular, moderate in the sanguine temperament, and tolerably lively in the bilious, constitutes, when it is excessive, the *nervous* temperament. This is seldom original, but more commonly acquired, and arising from a sedentary life, habits of pleasure, and an unnatural state of mind, kept up by reading works of imagination, &c. Soft and small muscles, and consequently inconsiderable size of body, lively sensations, promptitude and variability of decision, are marks of this temperament: it is often exhibited in vapourish women, in whom, however, it frequently exists with tolerable embonpoint, the predominance of the nervous system being connected with a moderate development of the lymphatic system. Convulsions are not unfrequent in such individuals. Antispasmodics succeed best in the treatment of their diseases, which always borrow their hue, more or less, from the temperament. This, like the melancholic, is not so much a natural constitution of the body, as the first stage of a disease. It exists only, as the nervous affections, to which it disposes, in societies arrived at a high pitch of civilization, when man is as remote as possible from the state of nature. The Roman women were not subject to nervous

disorders until the commencement of those depraved manners, which signalized the downfall of the empire. Vapours were extremely common in France during the 18th century, in the times that preceded the ruin of the monarchy, and numerous works appeared on the subject within a short time. Tronchin of Geneva acquired very extensive reputation and a large fortune by his skill in treating these disorders: he made idle women exercise themselves habitually, till they were fatigued, and restricted them to simple and wholesome food.

We cannot doubt, that the peculiar bodily dispositions, on which the differences of temperament are grounded, are coeval with our birth; but they appear to be modified, or even entirely changed by education, mode of life, climate, and contracted habits. The prevalence of particular temperaments in certain countries shews us the influence of climate. The bilious characterizes the inhabitants of southern climates; the sanguine those of the north; the phlegmatic constitution prevails in cold and wet countries, as Holland, &c. We rarely meet with individuals, who present the characters assigned to the various temperaments in all their purity, consequently the sketches here given of them are abstractions, which it is difficult to realize. The sanguine constitution is directly opposite to the melancholic, and never unites with it: we may make the same observation of the bilious and phlegmatic: yet a person, who is sanguine in his youth, may become melancholic at a subsequent period of life; for man never remains as he came from the hand of nature: modified by every thing that surrounds him, his physical properties, as well as his character, present numerous differences at the different periods of his life.

Proportions.—The proportions which the parts of the body bear to each other, when its growth is completed, must also be considered in this division of our subject. We have very little exact knowledge concerning these; they are hardly the same in any two individuals. Repeated observations alone can ascertain a standard, by which we may be enabled to form a perfect idea of the natural and best proportions of the human figure. The ancients made statues so exquisitely beautiful, that they have uniformly been regarded as exact representations of the most perfect human forms. These, which were only copies, are now considered as originals, because they were not imitated from an individual, but from the whole species, so attentively compared, and diligently observed, that it is impossible to find an equal degree of symmetry and proportion in any one man that ever existed. We shall, therefore, relate the dimensions of the different parts which these artists have fixed as standards of perfection. The height of the body is ten times the length of the face; and each face, or tenth of the body, is divided into three equal parts; the first commences at the springing of the hair on the forehead, and terminates at the root of the nose; the nose is the second division; and the third extends from the nose to the end of the chin. The term nose, or length of a nose, is used to denote the third of a face, or the thirtieth part of the body. The first face begins at the root of the hair, above the forehead, and extends to the end of the chin; but, from the top of the forehead to the crown, there is still a third of a face or a nose in height. Thus, from the top of the head to the end of the chin, there is a face and a third; from the chin to the juncture of the clavicles, two-thirds of a face; and, therefore, from the top of the head to the breast is twice the length of the face, or the fifth of the body. From the joining of the clavicles to the under part of the breasts, they reckon one face; from this to the

navel is a fourth face; and the fifth extends from the navel to the division of the inferior extremities, which should complete half the length of the body. Two faces are exhausted between the thigh and knee, to the last of which they allow half a face, being the first half of the eighth face; two faces are assigned between the knee and the top of the foot, and from that to the sole half a face, which completes the ten faces, or the length of the body. This division has been established from men of ordinary size; but in those of higher stature, they allow half a face additional between the breasts and the commencement of the thighs, which, in tall men, is not the middle of the body.

When the arms are fully extended in a horizontal line, the space between the tops of the middle fingers is equal to the length of the body. The space between the two great toes, when the feet are separated as widely as possible, is the same length. From the pubes to the heel is one-half of this length.

From the joining of the collar bones, to the articulation of the shoulder bone with that of the arm, is one face. When the arm hangs down, or is bent forwards, it is four faces in length; two between the shoulder and elbow, and two between the elbow and the root of the little finger; five faces, therefore, from the joining of the collar bones, and the same number for the other arm, make up the length of the body; about half a face remains for the length of the fingers; but it must be remarked, that this is lost in the elbows and shoulders, when the arms are extended. The hand is about a face in length, the thumb a third of a face, or a nose, and the longest toe is of the same length with the thumb. The under part of the foot is equal in length to the sixth part of the length of the body; of this the tarsus composes three, the metatarsus five, and the toes four.

It is very difficult to fix the proportional thickness of the different parts of the body. The changes are so great when the same man is thin or fat, and the action of the muscles, in different positions, creates so much variety in the dimensions of the parts, that it is almost impossible to set down any fixed rules on the subject. The circumference of the trunk, about the chest or abdomen, equals half the length of the body.

Strength of the Body.—It is difficult to form any satisfactory comparison between the strength of men and of animals. The habit of exertion, the kind and quantity of food, the state of health, and many other causes, have such effect on the vital powers of the muscles, that it is hardly possible to perform experiments under circumstances in all respects similar. Desaguliers tells us, that by means of a certain harness, by which every part of a man's body was proportionally loaded, the person employed in the experiment could support, in the erect posture, a weight not less than 2000 pounds. A horse, which is about six times the size of an ordinary man, ought, therefore, when managed in the same manner, to bear 12 or 14,000 pounds, a much greater weight than that animal can support, even when it is distributed with every possible advantage.

The strength of animals may likewise be estimated by agility, and perseverance in labour. Men, when accustomed to running, are able to outstrip horses in the long run: a man will accomplish a long journey sooner, and be less fatigued, than the best road horses. The royal messengers of Ispahan, who are trained to running, go thirty-six leagues in fourteen or fifteen hours; we are assured by travellers, that the Hottentots outrun lions in the chase; and that those savages, who live by hunting, pursue and even catch deer, and other animals of equal swiftness. Many

Other stories are told of the amazing nimbleness of savages, of the long journies they accomplish on foot over the most craggy mountains, where there is no path to direct, but every obstacle to obstruct their progress. These people are said to travel 1000 leagues in six weeks, or at most in two months. If we except birds, whose muscles are proportionally stronger than those of any other animals, no creature could support such long continued fatigue. Civilized man is ignorant of his own strength; nor is he sensible how much he is weakened by effeminacy, nor to what extent he might recover his native force by an habitual and vigorous exercise of his powers.

Age of Decline.—Every object in nature must change and decay; the bodies of men, when arrived at full maturity, begin to decline. The waste is at first insensible, and several years frequently revolve before we perceive any considerable alteration. The deposition of fat may perhaps be regarded as the first step towards decay; it is an addition of superfluous matter, loading the body with an useless weight. As the quantity of it augments, the body loses its former lightness and freedom of motion, the members become unwieldy, and extension is acquired at the expence of strength and activity. But the most unequivocal signs of approaching old age are the cessation of the catamenia in women, often attended with a development of the beard, diminished sexual appetite in men, the approach in both of what has been called the dryness of old age, (*siccitas senilis*), and a sensible diminution of the vital forces. The epocha of these changes is from forty to forty-five in women; from forty-five to fifty in men: peculiar causes may either accelerate or retard the period. The individuals of both sexes are now no longer capable of exercising that most important function, the propagation of the species; their sexual life is at an end. Diminished activity of the senses and brain, impaired vigour in the moving organs, and lessened energy of all the internal functions, gradually come on after this great revolution in the animal economy. Considerable organic changes are gradually developed; the motion of decomposition begins to predominate in the internal functions, and the volume of the whole body is reduced. The cellular substance, soft and flexible in the youth, is converted into long and hard threads; it undergoes, over the whole body, a change that cannot but impair the mobility of the organs. The yielding skin of the infant, which has the softness of velvet in the young woman, grows rough and harsh; a tawny and disagreeable hue takes place of its fresh redness; its contractility is destroyed, the absorption of the fat leaves it unsupported, and hence wrinkles are produced. They are first seen in the eye-lids, and extend over the whole body; but we notice them more particularly in the face, on the wrinkled front of which approaching decrepitude is marked in most legible characters. So hard does the texture of the skin become in very old individuals, that considerable force must sometimes be used to penetrate it with a knife. The hair partakes of the same changes with the skin; it turns grey, becomes much thinner, then assumes a white colour, and is at last entirely lost.

The cornea of the eye is rendered flatter, so that its power of refracting the rays of light, that come from near objects, is diminished. The vision of distant objects, however, is still perfect; and the use of convex glasses supplies the imperfection in the sight of what is near. A white circle is often developed in the cornea, near its attachment to the sclerotica, and has been called *arcus senilis*.

The arteries are not exempt from the general decay; the larger trunks are dilated, their coats are more or less converted into a substance of cartilaginous or bony hardness,

and assume a brittle texture. The process of ossification in the smaller tubes reduces their calibre. The capillaries are greatly diminished in number. Hence injections, particularly minute ones, succeed very imperfectly in old bodies. This change affects organs of every description; the same parts which exhibited innumerable blood-vessels in the growing body, possess now but few and scattered ramifications. The veins are enlarged and varicous.

The muscles become tough, and are rendered unfit in animals for the purposes of the table; fat is deposited among their fibres, and the tendinous parts increase in their proportion. They feel, however, at this time actually soft and flabby.

The bones receive an undue deposition of earthy matter, lose their cohesion, break very easily, and unite after fractures very slowly and imperfectly. The cartilages become brittle, and in many instances are ossified; the ligaments are rendered harder, but are less capable of resisting extension. The teeth fall out.

Analogous changes take place in all parts of the body, but are not equally obvious in all. Yet all the organs have something peculiar in their characters at this time, by which we can easily distinguish them from those of young individuals.

But the most important alterations are those which affect the vital properties, and consequently, the functions of the body. These changes are often seen when the above-mentioned alterations of structure are not visible to any very great degree. The external senses decay; vision becomes dim, and hearing dull; the operations of the intellect are affected in the same manner, attention and perception are weakened, the memory becomes confused. Thus, the relations of the old man to the external world are gradually destroyed; he sinks into second infancy, becomes incapable of judging and willing, and has his intellectual world confined to a few confused recollections, which soon disappear. When he is thus shut out from new impressions, he sleeps most of his time, awakening only for the purpose of taking food; thus he is reduced to a kind of vegetative existence.

The organs of motion lose their vitality in an equal degree with those of sensation and volition. The movements are slow, tremulous, and uncertain. The erector muscles of the trunk can no longer support it in the upright posture, hence the body is bent forwards, and the legs become unable to sustain and move the body. The intervertebral fibro-cartilages are compressed and reduced in size, and the stature, consequently, experiences a real diminution.

Digestion, and the other parts of the assimilating process, are executed slowly and imperfectly: the loss of the teeth is disadvantageous to the former. Food is taken at longer intervals; the bowels become torpid; and the feces and urine are longer retained.

The vigour of the circulation is impaired; the pulse becomes slower; the extremities of the body are soon rendered cold, and their vitality is so weak, that they easily slough. For a statement of the number of the pulse at different ages, see the article CIRCULATION.

Decrepitude.—From the end of manhood to death, there is a gradual progress, in which no stages can be very distinctly marked. Yet the first years of decay are sometimes included under the term of green old age; in which all the functions are still performed, but with lessened energy. This may reach, with considerable latitude, however, to the sixtieth year. In this time the memory grows dull: former events are remembered, but the more recent soon escape. This is succeeded by decrepitude. The nervous system is now rendered nearly useless: the old impressions are effaced, and no new ones received. No desire remains but that of food,

which is the last to leave us: in the end food is not taken, unless it is offered. The irritation of the fæces in the large intestine is not perceived before death; and sleep is almost constant. A. de Moivre, who died at the age of eighty-eight, slept twenty hours in the twenty-four during the last year of his life. Complete deafness and blindness come on. The muscles are first exceedingly weak, and then lose their power entirely, so that old people are obliged to lie constantly in bed. Excessive emaciation takes place. The heart at last fails; its pulsations are reduced to fifty, forty, thirty; and become intermittent; and the heat of the frame is no longer kept up.

Death.—For a more particular account of the changes preceding death, and of death itself, we refer to that article. We have only to add here a few observations concerning the apprehensions generally entertained of this event. We have shewn, in the preceding sketch, that life both commences and terminates by imperceptible degrees. Why then should we be afraid of death, if we have no reasonable apprehensions of its consequences? why dread this single moment, which has been preceded by so many others of the same order? since death is fully as natural as life, and both arrive in the same manner, without our being able to perceive their approach. If we inquire of those who are accustomed to observe the actions and sentiments of the dying, we shall find that, except in a few acute diseases, attended with agitations and convulsions, which exhibit only the appearances of pain, most men expire quietly, and without the smallest indication of uneasiness. Even when persons seem to be afflicted with the most dreadful agonies, these have no existence but in the imagination of the spectator: the truth of this has been repeatedly attested by many persons who have recovered after the most violent commotions and convulsions, yet were unable to recollect any thing they had felt during this seemingly distressful situation. The greatest part of mankind die, therefore, without being sensible of the fatal stroke; and of those who preserve their senses to the last groan, there are very few who do not entertain some hope of recovery. Death is a spectre which terrifies us at a distance, but disappears when we approach it more closely. That the succession of ideas may be so rapid as to give to a moment the appearance of an age, and thus to subject our departure from existence to excruciating torture, has been supposed without a single proof in its favour, and against all probability and analogy. Excessive pain extinguishes all reflection; yet symptoms of the latter have sometimes appeared in the very moment of violent death. When Charles XII. received the blow, which terminated, in an instant, both his enterprises and his existence, he clapped his hand upon his sword. This mortal pang, since it excluded not reflection, could not be excessive. He found himself attacked, and determined to defend himself; it is evident, therefore, that he felt no greater pain than he would have suffered from an ordinary stroke.

If it were as easy to dissipate the terrors caused by the anticipation of what is to happen after death, and to quiet the minds of men concerning the undiscovered country beyond the grave, the Tartarus, with its judges and furies, its lakes of liquid fire, and the other hellish apparatus, as it is to prove that the termination of existence is not physically painful, the human race would be most signally benefited, and would no longer have to envy brutes their peaceful death.

Rigidity of the body, joined with coldness, flaccidity of the cornea, open state of the anus, lividity of the back, and a cadaverous odour, where they exist together, prove very satisfactorily that death has taken place.

It is hardly possible to set down any ages as the natural period

of life, as the most common and regular limit of advanced old age. Blumenbach observes, however, that a careful inspection of several bills of mortality has shewn him, that a comparatively considerable number of Europeans reach their eighty-fourth year, while very few survive it.

On the whole, although the human race is destroyed in such numbers, among other causes, from the weakness of the thread of life in the early years, by the intemperance of manhood, by disease and accident, that not more than seventy-eight out of a thousand die a natural death; yet, where human longevity is compared to the period of life of the other mammalia under similar circumstances, it will be soon discovered, that of all the complaints concerning the misery of human life, none is more unfair than that of its shortness.

On the very interesting subjects of the probabilities of life at different ages, the annual mortality in different countries and situations, the number of marriages, deaths, and births, the rate of increase of population, and the proportions destroyed in the different ways by which existence is terminated, see *EXPECTATION of Life, LIFE-ANNUITIES*, and an excellent table by M. Dupré de St. Maur, drawn up from the lists of twelve country parishes in France, and three in Paris, and published by Buffon, in his *History of Man*, sect. 5. *MORTALITY, MARRIAGE, and POPULATION*. For an account of individuals who have reached an unusual age, and of the circumstances, under which this has happened, see *Haller's Elementa Physiologiæ*, lib. xxx. section 3; the article *LONGEVITY* in this *Cyclopædia*; and sir John Sinclair on *Health and Longevity*, 4 vols. 8vo.

II. *History of the Species.*

In the diversity of the regions which he is capable of inhabiting, the lord of the creation naturally holds the first place among animals. His frame and nature are stronger and more flexible than those of any other creature; and he dwells, without injury, in all situations on the surface of the globe. The neighbourhood of the pole and the equator, the highest mountains and the deepest rivers are occupied by him: his strong but pliant body bears cold, heat, moisture, light or heavy air; he can thrive any where, and runs into less remarkable varieties than any other animals which occupy so great a diversity of abodes;—a prerogative so singular, that it is not to be overlooked.

What climates, what degrees of heat and cold can man bear? where does he live? and how is he able to endure such various abodes? Is he indebted for this privilege to the strength and flexibility of his organization, or, as Buffon asserts, merely to his reason? Does he constitute a distinct species; or is he allied in kind to the ourang-outang? How do climate, food, and similar causes operate on him? Are these sufficient to account for all the diversities hitherto observed; or must we suppose that several individuals were originally created, each for its own climate? What country did he first inhabit, and what was the appearance of the original man? Did he go erect, or on all fours? was he a Patagonian, or an Eskimau, Negro, or Georgian? Such are the important questions which we have to consider in the present division of the article;—questions, of which a full discussion would require a much greater extent and variety of knowledge than the writer can lay the least claim to, as well as a much larger portion of space than the limits of this work will allow. We must, therefore, be contented with exhibiting a few hints, rather than a complete view of the matter.

Abode of the human Species.—The situations occupied by man in the present times, extend as far as the known surface of the earth. The Greenlander and Eskimau live in the eightieth, and even, perhaps, in still higher degrees of north latitude.

latitude. Noogfack, a Danish settlement, lies in 72° north latitude; and the Greenlanders themselves go much higher. Three Russians lived between six and seven years on Spitzbergen, in latitude between 77° and 78° . See Dr. Aikin in the Manchester Society's Memoirs, vol. i. p. 96. The Negro lives under the equator, and all America is inhabited even to Terra del Fuego. Cook discovered land about the 58^{th} and 60^{th} degrees of south latitude, which he called Sandwich land; and a cluster of islands as far as the 66^{th} degree, on which he saw no men. Very probably there are no human inhabitants here: but it is sufficiently proved that places at least as cold are habitable. Perhaps we are not quite warranted in asserting that there are men in the interior of Africa; yet the accounts received from those on the coasts induce us to believe that these regions are in some degree peopled. Hence we find that man is capable of existing and propagating his species in the hottest and coldest countries of the earth.

The greatest natural cold which has been ascertained by thermometrical measurement, was that experienced by the elder Gmelin in the year 1735 at Jeniseik in 58° north latitude, and 110° east longitude (from Ferro). The mercury fell to 126° below 0. (Flora Sibirica, pref.) The sparrows and jays were killed. When Pallas was at Krasnaiarsk 56° north latitude, and 110° east longitude, the thermometer fell to 80° below 0; and the quicksilver froze in the bulb. A mass of pure mercury, exposed in the open air, was frozen. (Travels in Russia, pt. 3.) Our own countrymen experienced apparently as severe a degree of cold on the Churchill river in Hudson's Bay. Brandy was frozen in the rooms where they had fires. (Phil. Trans. N^o 465.) Yet the Canadian savages and the Elkimaou go to the chase in this temperature; and the inhabitants of the countries visited by Gmelin and Pallas cannot remain constantly in their houses during their winters. Even Europeans, accustomed to warmer climates, can undergo such cold as we have just mentioned, and escape unhurt, if they take exercise enough. The Danes have lived in Greenland in the 72° north latitude; and the Dutch, under Heemskerck, wintered at Nova Zembla in 1597, in 76° north latitude. Some of them perished; but those who moved enough, and were in found health at first, withstood the dreadful cold, which the polar bear (*ursus maritimus*), apparently born for these climes, seems to have been incapable of supporting; for the journal states that, as soon as the sun sinks below the horizon, the cold is so intense, that the bears are no longer seen, and the white fox (*canis lagopus*), alone braves the weather. (Voy. de la Comp. des Indes, part i.) For an account of other examples, and particularly of one, in which three men remained for between six and seven years in 78° north latitude, see Dr. Aikin's Memoir, already quoted, concerning the attempts to winter in high northern latitudes.

The power of the human body to withstand severe degrees of cold will appear in a more remarkable light, when we observe what heat it is capable of bearing. Boerhaave asserted, that a heat of from 96° to 100° would be fatal to man. Adanson saw the thermometer in the shade at $108\frac{1}{2}$ at Senegal in 17° north latitude; and Buffon cites an instance of its being seen at $117\frac{1}{2}$. Probably the country to the west of the great desert is still hotter from the effect of the winds which have blown over the whole tract of its burning sands. When the sirocco blows in Sicily, the thermometer rises to 112° , according to Brydone. Dr. Chalmers observed a heat of 115° in South Carolina, in the shade: (On the Weather and Diseases of South Carolina;) and Humboldt experienced a temperature from 110° to 115° in the Llanos or deserts near the Orinoco, in South America. (Tableau Physique des

Regions Equatoriales.) Much greater degrees of artificial heat have been supported. See HEAT, *Animal*.

Thus we see that man can sustain all possible degrees of atmospheric heat and cold. He has an equal power of supporting varieties of pressure. We may reckon the ordinary pressure of the air, at the level of the sea, at 32,235 lbs. for the whole surface of the body; supposing the barometer to stand at 30 inches. If we ascend to a height of 12,000 feet, (extensive tracts in South America, inhabited by thousands, have this height,) the barometer stands at $20\frac{1}{4}$ inches, and the pressure is 21,750. Condamine and Bouguer, with their attendants, lived three weeks at a height where the barometer stood at 15 inches 9 lines, and the pressure must consequently have been 16,920. (Mem. de l'Acad. des Sciences, 1744.) In the Peruvian territory, extensive plains occur at an altitude of 9000 feet; and three-fifths of the viceroyalty of Mexico, comprehending the interior provinces, present a surface of half a million of square miles, which runs nearly level at an elevation of from 6000 to 8000 feet. Mexico is 7475, and Quito 9550 feet above the sea. The hamlet of Antisana, 13,500 feet above the level of the sea, is the highest inhabited spot on the surface of our globe; but Humboldt ascended to 19,300 feet. (Tableau Physique des Regions Equatoriales; et Tableaux de la Nature.) There are no instances of men living under a pressure much greater than we have just mentioned: the depths to which the earth has been penetrated, in the operations of mining, are trifling in this point of view. In diving, however, the body is subject to, and can bear several atmospheres; as, on the contrary, in balloons, men have ascended beyond any point of elevation on the surface of the earth, and have consequently been exposed to a much more considerable diminution of the ordinary pressure than what we have stated above.

Food.—The great variety of substances, which man is not only capable of digesting, but from which his organs can extract wholesome nourishment, contribute very essentially to his wide extension over the surface of the earth. We have already explained, under the article DIGESTION, that almost the whole animal and vegetable kingdom afford food to man. Under particular circumstances, he can not only derive his nutriment exclusively from the animal kingdom, as in New South Wales, and in the Archipelago between Asia and America, from fish; in the islands to the south of Iceland, from fish and puffins (see sir G. Mackenzie's Travels in Iceland); but can consume what appears to us the most filthy and disgusting objects. The Greenlander and the inhabitants of Alaska eat the whale, and can digest this hard and revolting food without the assistance of cookery. The former bury a seal, when they catch one, under the grass in summer, and the snow in winter, and eat the half-frozen half-putrid flesh with as keen a relish as the European finds in his greatest dainties. (Cranz Hist. of Greenland.) They drink the blood of the seal while warm, and eat dried herrings moistened with whale oil. They mix fresh, putrid, and half-incubated eggs, whortle berries, and angelica, in a bag of seal-skin, pour whale-blubber on it, and reserve the infernal mixture as a delicacy for the winter. The people of admiral Monk, and some Russians, cast away on one of the Aleutian islands, greedily consumed the putrid remains of a whale; and the Greenlanders always dispose of the whales stranded on their coasts in this way, not desisting, however far putrefaction may have proceeded, till the whole is gone.

Even the earth, impregnated with the reliquie of animal and vegetable matter, affords food to some savages. The Ottomagues, on the banks of the Meta and the Orinoco, feed

feed on a fat unctuous earth, or a species of pipe-clay tinged with a little oxyd of iron. They collect this clay very carefully, distinguishing it by the taste: they knead it into balls of four or six inches in diameter, which they bake slightly before a slow fire. Whole stacks of such provisions are seen piled up in their huts. Those clods are soaked in water, when about to be used; and each individual eats nearly a pound of the material every day. The only addition which they occasionally make to this unnatural fare, consists in small fish, lizards, and fern roots. The quantity of clay that the Ottomaques consume, and the greediness with which they devour it, seem to prove that it does more than merely dislend their hungry stomachs, and that the organs of digestion have the power of extracting from it something convertible into animal substance. Humboldt *Tableau Phytique des Regions Equatoriales*.

The researches of Meiners respecting food seem to have exhausted every accessible authority on the subject: his deductions, supported by an almost infinite number of quotations, exhibit so complete a view of the matter, that we present them to the reader in his own words. "The common positions concerning the earlier use of vegetables, and the effects of vegetable and animal food on the dispositions of people, have been brought forwards by men not acquainted with all the facts which history presents. There were formerly, and still are, many people, particularly among the dark coloured nations, who eat nothing, or almost nothing but flesh; and that with little or no preparation. Examples of this are afforded in Asia, by the Huns, Calmucks, and people of Thibet; by the Burates, Tungooses, Kamtschatkans, and eastern islanders; by the Ostiaks and Samoiedes, whom the Russians were obliged to imitate in Nova Zembla, and the Eastern ocean; by the Woguls, Circassians, Mingrelians, and Abcaffas; and lastly, by some tribes in Babylon: in Europe, by the Alani, all the Celtic people, the Tartars of the Crimea, and even the inhabitants of St. Kilda: in America, by the Esquimaux, the Greenlanders, the North American savages, the Peruvians, and the inhabitants of Terra del Fuego: in Africa, by the Ethiopians and Gallas: in the southern countries, and the islands of the South Sea, by the New Hollanders, New Zealanders, and the inhabitants of the Friendly and Society islands.

"On the contrary, there have been, and still are, many people who live almost exclusively, or wholly on vegetables. Such are the Cretans, Spartans, and Romans, in certain periods; most of the Slavonic tribes; the Turks, Arabians, and Persians; the Mahometans, and still more the Brahmans in Hindoostan; the Chinese, Japanese, and certain of the Javanese; most of the Otaheitans, and inhabitants of the Marian islands; lastly, the Egyptians, Moors, Negroes, Hottentots, and inhabitants of Sennaar.

"The most common animal food is fish, which, in the warm climates of Asia and Africa, is seldom eaten except in a stinking or putrid state. After fish come pigs and dogs; then camels, mules, horses, and locusts. The southern people prefer smoked and salted, the northern fresh meat. The modes of preparation are very various: very few boil; most either dry or roast their flesh, and this in very different ways.

"Of vegetable foods, maize deserves the first place; then bananas, potatoes, yams, and other roots; rice, and millet. The history of our European corn is very obscure. Originally the corn was eaten either raw or roasted; or else it was pounded or bruised, and the meal taken, either raw, or roasted or boiled. Examples of these methods are still found. The vine, as well as some of our kinds of corn,

are produced in much more southern countries than is commonly supposed.

"Of trees that produce fruits, those of the palm kind should be first mentioned; the figo and bread-fruit trees are much less widely extended. Many people eat acorns or chestnuts, or the rind or exuded juices of well-known trees; or the pith, fruit, or roots of trees that we know little of. In other situations, moss or berries, or the roots and bulbs of known plants, have been employed. The fruit trees of our climates grow neither in the torrid nor in the frigid zones. The use of hot spices generally increases with the heat of the climate. The perfectly irregular meals of savages are less remarkable than the quick eating of the orientals.

"The orientals are the most moderate; all of Mongolian or mixed origin, in all climates, and even in the torrid zone, are the most voracious. Respectable writers bear testimony to this voracity in the Nogays, Tungooses, Baschkirs, and Kirgises; in the Greenlanders, Laplanders, and Fins; in the Hindoos, Tunquinese, and the inhabitants of Laos; in the Negroes and Hottentots; in the North and South Americans. There are situations, in which the appetite of new comers is much increased, or a greater quantity of food is required to support the bodily powers.

"These voracious people swallow with brutal avidity the most disgusting and difficultly digestible substances. The Calmucks devour putrid and stinking matters, the after-birth of animals, marmots, mice, otters, birds of prey, foxes, and wolves; but not dogs nor weasels. The Jakuts eat carnivorous animals; and the after-birth of their women is a delicious morsel, to which they invite their friends: they will not, however, touch frogs or pigs. The Tungooses and Ostiaks swallow slimy mud: the former also eat lice and the snot of their children. The Samoiedes eat putrid relics of horses, cats, dogs, whales, &c.; and the Kamtschatkans indigestible fungi. The women of the former used to eat the after-birth, that they might conceive again sooner. The Tschutskis and their guests drink the urine of the women; and the inhabitants of the Fox islands, besides lice, eat raw whale-blubber: they also lick themselves dry, after washing with urine. The Laplanders chew tobacco; flick it behind their ears, and then chew it again. The Tunquinese eat tigers, lions, snakes, bats, elephants, stinking and uncleaned fish; the Chinese, dead dogs, horses, and rats; the Arracanese, Siamese, and Formosans, besides such things, devour entrails, with all their contents. The inhabitants of the Bashee islands in the Indian ocean, who are in other respects cleanly, consider the contents of a goat's stomach as a great luxury. Crocodiles, eagles, ostriches, hippopotami, serpents, raw and putrid buffaloes and elephants, uncleaned entrails, toads, rats, and worms, the most stinking carcases, chalk, and earth, are eaten by the Negroes. The Bosjesmen make themselves fat with ants, and maggots of wood; and, like the Negroes, are fond of elephants' flesh, which they cut in pieces, and dry in the sun. The women of the Americans free each other from vermin, and eat them; and the contents of a rein-deer's stomach, mixed up with whale-oil or bears'-grease, is deemed a *bonne bouche* by the Greenlanders. They also cook fish with blubber, chewing them, and spitting them into the vessels, that nothing may be wasted: they stroke off the sweat with their fingers, and swallow it. The Californians not only consume lice, uncleaned entrails, serpents, lizards, insects of all kinds, maggots from rotten wood, spoiled corn full of worms, but also dry leather and clay; undigested grains of the pitochais, which they get from human excrement; and lastly, rats and mice, which they put on the fire

for a short time, and then swallow quite bloody. Besides other matters, the Brasilians and Chilese eat the bleeding hearts of their enemies; and the former also the bodies and broken bones of their children and leaders. The Caribs, and other people on the Orinoco, like the Negroes, eat chalk and clay; and make with them, and spoiled maize, balls which they moisten with turtle fat, and swallow with great delight.

“Almost all people, even the wildest and most stupid, have devised methods for intoxicating or stupifying themselves. For this purpose they either smoked or chewed leaves or herbs, in some instances. The orientals, who possessed the western half of southern Asia, and the north-west side of Africa, have from early times preferred the use of opium; and the south-east nations, and their colonies, that of betel. The orientals and the East Indians drink wine to excess; but they prefer the spirit extracted from sugar or rice, or still stronger liquors. The Russians in Siberia, and the European colonists in the torrid zone, drink brandy in great quantities. Palm and honey wine are very common in hot countries. There is scarcely any herb or vegetable production, and much less any article of vegetable food, from which intoxicating drinks have not been extracted. Bread, malt, meal, fruit, fago, cassava (*juca dulce et amarga*), potatoes, the aloe (*sagave americana*), millet, and mares' milk, have been used for this purpose. The chica of the Americans, of which maize is the basis, is the most disgusting liquor. Very few people have been entirely unacquainted with lulling liquors: the love of these, however, seems particularly strong in the ugly races of Asia and America.” *Meiners' Grundriss*, p. 140—162.

On the subject of eating human flesh, see the articles CANNIBAL and ANTHROPOPHAGI.

In almost all ages there have been disputes concerning the food best suited to the nature of man; whether a mixed diet, or one purely animal or vegetable, is most favourable to the development of the bodily and mental powers. “The Pythagorean diet,” says Buffon, “though extolled by ancient and modern philosophers, and even recommended by certain physicians, was never indicated by nature. If man were obliged to abstain totally from flesh, he could not, at least in our climates, either exist or multiply. An entire abstinence from flesh can have no effect but to enfeeble nature. To preserve himself in proper plight, man requires not only the use of this solid nourishment, but even to vary it. To obtain complete vigour, he must choose that species of food which is the most agreeable to his constitution; and as he cannot preserve himself in a state of activity but by procuring new sensations, he must give his senses their full stretch, and eat a variety of meats, to prevent the disgust arising from an uniformity of nourishment.” We are told, on the other side, that, in the golden age, man was as innocent as the dove; his food was acorns, and his beverage pure water from the fountain: finding every where abundant subsistence he felt no anxieties, but lived independent, and always in peace both with himself and the other animals. But he no sooner forgot his native dignity, and sacrificed his liberty to the bonds of society, than war and the iron age succeeded that of gold and of peace. Cruelty and an insatiable appetite for flesh and blood were the first fruits of a depraved nature, the corruption of which was completed by the invention of manners and arts. Either immediately, or remotely, all the physical and moral evil, by which individuals are afflicted and society laid waste, arose from these carnivorous practices.

We cannot give our approbation to either of these repre-

sentations, both of which are contradicted by the only criterion in such questions, an appeal to experience. That men can be perfectly nourished, and that their physical and intellectual capabilities can be fully developed in any climate, by a diet purely vegetable, has been proved by such abundant experience, that it will not be necessary to adduce any formal arguments on the subject. The representations of the Pythagoreans are the mere offspring of imagination. We have not the shadow of a proof that this state of ideal innocence, of exalted temperance, of entire abstinence from flesh, of perfect tranquillity, of profound peace, ever existed, or that it is more than a fable designed to convey to us moral instruction. If the experience of every individual were not sufficient to convince him, that the use of animal food is quite consistent with the greatest strength of body and of mind, the truth of this point is proclaimed by the voice of all history. A few hundreds of Europeans hold in bondage the vegetable eating millions of the East. We see the carnivorous Romans winning their way, from a beginning so inconsiderable, that it is lost in the obscurity of fable, to the empire of the world; we see them, by the power of intellect, establishing that dominion which they had acquired by the sword, and furnishing such compositions in poetry, oratory, philosophy, and history, as are at once the admiration and despair of succeeding ages: we see our own countrymen rivalling them in arts and in arms, exhibiting no less signal bravery in the field and on the ocean, and displaying in a Milton and Shakspeare, in a Newton, Bacon, and Locke, in a Chatham, Erskine, and Fox, no less mental energy: yet, with these proofs before their eyes, men are actually found, who would have us believe, on the faith of some insulated, exaggerated, and misrepresented facts, and still more miserable hypotheses, that the development, form, and powers of the body are impaired and lessened, and the intellectual and moral faculties injured and perverted by animal diet.

The present seems a very proper place for considering a question, that is frequently agitated on this subject; whether man approaches most nearly to the carnivorous or herbivorous animals in his structure? We naturally expect to find, in the figure and construction of the teeth, a relation to the kind of food which an animal subsists on. The carnivorous have very long and pointed cuspidati or canine teeth, which are employed as weapons of offence and defence, and are very serviceable in seizing and lacerating their prey: these are three or four times as long as the other teeth in some animals, as the lion, tiger, &c. and constitute very formidable weapons. The grinding teeth have their bases elevated into pointed prominences; and those of the lower shut within those of the upper jaw. In the herbivorous animals, these terrible canine teeth are not found, and the grinders have broad surfaces, opposed in a vertical line to each other in the two jaws: enamel is generally intermixed with the bone of the tooth in the latter, and thus produces ridges on the grinding surface, by which their operation on the food is increased: in the former, it is confined altogether to the surface. For further details on this subject, see MAMMALIA. The articulation of the lower jaw differs very remarkably in the two kinds of animals: in the carnivorous, it can only move forwards and backwards; in the herbivorous it has, moreover, motion from side to side. Thus we observe, in the flesh eaters, teeth calculated only for tearing, and subservient, in part at least, to the procuring of food, as well as to purposes of defence, and an articulation of the lower jaw that precludes all lateral motion: in those which live on vegetables, the form of the teeth, and the nature of the joint, are calculated for the lateral

ral or grinding motion: the former swallow the food in masses, while in the latter it undergoes considerable comminution before it is swallowed. The teeth of man have not the slightest resemblance to those of the carnivorous animals, except that their enamel is confined to the external surface: he possesses, indeed, teeth called canine, but they do not exceed the level of the others, and are obviously unsuited to the purposes which the corresponding teeth execute in carnivorous animals. These organs, in short, very closely resemble the teeth of monkeys, except that the canine are much longer and stronger in the latter animals. In the freedom of lateral motion, the lower jaw of the human subject resembles that of herbivorous animals. In the form of the stomach again, and, indeed, in the structure of the whole alimentary canal, man comes much nearer to the monkey than to any other animal. The length and divisions of the intestinal tube are very different according to the kind of food employed. In the proper carnivorous animals the canal is very short, and the large intestine is cylindrical; in the herbivora, the former is very long, and there is either a complicated stomach, or a very large cæcum and a facculated colon. In comparing the length of the intestines to that of the body in man, and in other animals, a difficulty arises on account of the legs, which are included in the former, and left out in the latter: hence the comparative length of the intestinal tube is stated at less than it ought to be in man. If allowance be made for this circumstance, man will be placed on nearly the same line with the monkey race, and will be removed to a considerable distance from the proper carnivora. Soemmerring states that the intestinal canal of man varies from three to eight times the length of the body. (*De Corp. Hum. Fab. t. 6. p. 200.*) In Tyton's chimpanzee of 26 inches, the canal measured 159 inches, which is about six times the length of the body: in two sapajous and two monkeys, the intestines were respectively 62 and 96 inches, which must be considerably shorter in proportion, although the length of the body is not mentioned. P. 32.

The following are the comparative lengths of the canal and body in several simiæ, according to Cuvier, t. 3. p. 448. As the hind limbs are not included in the length of the body, it will be immediately apparent that the alimentary canal of these herbivorous animals is generally shorter than that of man.

	Body.	Intestinal Canal.

Man possesses a tolerably large cæcum, and a cellular colon, which we believe is found in no carnivorous animal. In general, then, the human teeth and joint of the jaw resemble most those of herbivorous animals: and man approaches most nearly in these, as well as in other points, to the monkey race, which are, in their natural state, completely herbivorous.

In stating these circumstances, we do not wish our readers to draw the inference, that man is designed by nature to feed on vegetables. The differences between him and other animals, render it difficult to apply to him reasonings drawn from them. The hands of man, and particularly his arts,

procure for him the food which carnivorous animals earn by their teeth. The processes of cookery bring what he eats into a different state from that in which it is employed by either carnivorous or herbivorous animals. Hence the analogy is too loose for us to place much confidence on the results of these comparative views. We must trust to experience alone for elucidating the great problem of diet: but the experimental mode of investigation is so difficult; mankind are so averse to relinquish long habits, and there are so many other causes affecting human health, that we are by no means sanguine in our expectations of important results. Before we can venture to draw any inferences on a subject, beset with so many obstacles, we want to know the effects of a purely animal diet on several individuals of different habits. We must have accurate reports of their state, both bodily and mental, and must learn the condition of two or three succeeding generations fed in the same way. A similar statement will be necessary on the operation of a strictly vegetable diet. The drink, too, is an important consideration. For further remarks on this subject, see **CORPULENCY** and **DIET**.

Abodes and Drefs of various Nations.—We shall employ on this subject the observations of Meiners, who has collected his materials from every accessible source of information, both ancient and modern, and subjoined the numerous authorities from which they are derived.

Abodes.—There have been more people than is commonly supposed, without any, or at least without any secure and protecting dwelling; and these were, without exception, dark coloured or ugly nations; such were the Fenni of Tacitus, the savages about Hudson's Bay, northwards from the river St. Laurence, and in North America in general, the Californians, Peruvians, the Indians near Garcias de Dios, the Brasilians, those of the Oronoco and Maranon, the New Hollanders, some of the New Zealanders, some savages near Abyssinia, and in Natal.

The first step was made by those who built huts inclosed on all sides, but such as were easily covered with leaves or branches, bark of trees or skins, and therefore admitted of being separated and conveyed from place to place. Almost all the inhabitants of northern Asia, Europe, and America; the Burates, and Tungooses; the Samoiedes, Jakuts, and Ostiaks; the Greenlanders, Laplanders, and people about Hudson's Bay; the Chilese, and some savages in Louisiana; and the lowest inhabitants of Sumatra, Arabia, and Hindoostan, have such huts.

More solid and perfect edifices were constructed with beams, or stones, or woodwork; the walls covered with earth. In this way the Greeks, Germans, and Slavons of ancient times built; the same method is adopted still by the Morlachians, the inhabitants of several German and Turkish provinces; the Finnic and mixed races in Europe and Asia; the Russians and Icelanders; several savages in America; most of the Negroes; the Cabyles and Moors in Africa, several of the Arabians, and Persians, Hindoos, Ceylonesc, Chinese, and Japanese.

The mode of building is modified by various causes. Constant danger taught the nations of the middle ages, the Greeks of the islands, the Mingrelins, the inhabitants of Sumatra, the Bashee islands, New Zealand, &c. to provide themselves with the means of safety. Those who are exposed to earthquakes, inundations, vermin, rapacious animals, will build differently from such as know nothing of these evils. Extreme heat and cold of the climate require different methods; pastoral and agricultural people will lodge themselves very differently. There are many reasons

why this part of the world has produced chef-d'œuvres of architecture, and why the subjects of the despots of Europe, Asia, and Africa, are worse off in their houses than the free subjects of the more happy states. In comparing the descriptions of the dwellings and cities of the Turks, Moors, Persians, Arabians, Hindoos, Siamese, Tunquinese, Chinese, inhabitants of Thibet, Formosans, and Japanese, we cannot help wondering at the remarkable uniformity of architecture in such different nations. The most uncultivated people in Africa and America had public buildings." Meiners *Grundriss*, chap. 5.

Dress and Ornament.—"As there have been people, without any secure habitation, so there have been many without any dress, or at least such as covered the greatest part of the body. The Celtic nations were formerly naked or nearly so; and this is the case at present with the Mingrelians, the inhabitants of Terra del Fuego and their neighbours, and the New Hollanders. The savages of California, Louisiana, the isthmus of Darien, Guiana, Brazil, and Paraguay, several islands of the South Sea, and several negroes, go also naked.

The place of clothing is supplied in the naked people by smearing the body with oil or grease, generally mixed with coloured earths or plants. Painting of the whole body, or of parts, and particularly of the face, has been a chief object and employment of vanity with nearly all the savage people of the world. One or the other was practised by the Celts, Persians, and Medes: the custom still prevails in Asia among the Brahmins, Hindoos, and their women; among the females of the Arabians, Persians, Turks, Armenians, Egyptians, and Mingrelians, to whom we may add those of the Greeks, Walachians, and Russians; also the Chinese, Peguans and Siamese, the New Hollanders, New Zealanders, inhabitants of several South sea islands, and the Kamtschatkans; the Negroes and Hottentots, and all the wild Americans, both north and south. The practice of puncturing and tattooing the skin, performed with very various objects, and on very different parts, has not been less universal; we find, at least, that it has existed among the Celts, the Egyptians, Syrians, Brahmins, and Arracanese, the Turks, Arabians, Moors, and the Formosans, the Tungoosees, Otiaks, Greenlanders, and eastern islanders, the North and South Americans, and the South sea islanders. Instead of punctures and lines incisions with a knife were made in some instances.

Great attention has generally been paid to decorating the hair, to changing its colour by powders and grease, to curling it in various ways, or adorning it with feathers and other articles. The women of the Greeks and Romans, even in their times of simplicity, were distinguished in this way, also the Turks and Moors and their women, the southern islanders, most of the negroes, and nearly all the American savages. Several people, from their notions of beauty, have employed themselves in staining, filing, and otherwise decorating their teeth: also in colouring and encouraging the growth of their nails. Still more extraordinary attempts at personal decoration have been made by the Giaga women, several negroes of both sexes, the Carib women, the Gallas, and the natives of Natal.

With the view of beautifying the person, the ears and nose have been perforated, and the lips and cheeks either slit up, or perforated. The latter practice has been observed chiefly in the inhabitants of the eastern islands, and the savages of Paraguay and Brazil; but it was much more common to make holes in the ears or nose, to hold rings or other ornaments. This was carried no where so far as in south America, the eastern islands, and those of the south sea. The taste for

rings, not only in the ears and nose, but also about the neck, arms, legs, body, &c. prevails still chiefly in Africa and Asia, where it has existed from the earliest times. The Europeans also, in the dark ages, took pleasure in founding and heavy ornaments. The decoration of the female head was formerly, and still continues, the most complex and heavy, in the oriental nations of Asia, and the mixed people of Siberia. The astonishing ornaments made of feathers are among the peculiarities of the Americans.

The inhabitants of cold climates resemble each other in their dress more nearly than those of warm ones. The latter wear either an apron or shirt, with or without breeches, mantle, and pelisse or covering of fur. The southern people distinguish themselves by having the head either covered or naked. Women have generally been clothed like the men. Leather and felt, and the most simple kind of weaving, appear to be all of nearly equal antiquity. Barbarous people generally like the most lively colours, but here, as in most other remarks on man in general, there are many exceptions. *Ibid.* ch. 6.

Does Man constitute a distinct Species?—The differences between man and animals constitute a very important subject in his natural history. We feel here, what we have often occasion to observe in the study of natural history, and particularly of zoology, that it is much easier to perceive, as it were intuitively, the distinctive characters of two neighbouring species of animals, than to express them in words. Thus we readily discern the difference between the rat and the mouse, the hare and the rabbit, though it would be much more difficult to describe clearly the characteristic marks on which that difference rests. That this kind of difficulty exists in the present subject has been candidly confessed by some great men. Linnæus, whose sagacity in perceiving the characteristic marks of the various objects of natural history, and in expressing them in appropriate language, has never been exceeded, observes in the preface of his *Fauna Suecica* "rem perquam arduæ indaginis esse pro priam tradere hominis differentiam specificam; et nullum se hactenus characterem eruere potuisse, unde homo a simia inter noscatur." In the *Système Naturel* he again says, "mirum adeo parum differre stultissimam simiam a sapientissimo homine, ut ille geodætes naturæ etiamnum quærendus, qui hos limitet;" accordingly he gives neither the generic nor specific character of man in that work, but puts him on a level with the long-armed ape, (under the name of *homo lar*.)

Other authors have distinctly asserted the opinion that man and the monkey, or orang-outang, belong to the same species; and are no otherwise distinguished from each other, than by circumstances, which can be accounted for by the different physical and moral agencies to which they have been exposed. (Monboddo on the Origin and Progress of Language, vol. i. and Ancient Metaphysics, vol. iii. Rousseau sur l'Inégalité des Conditions, note 10.) The former of these writers even supposes that the human race once possessed tails; and he says "the orang-outangs are proved to be of our species by marks of humanity that I think are incontestible." The latter conceives that the observations of travellers, concerning various animals of the monkey kind, prove the existence of wild men. "Toutes ces observations sur les variétés que mille causes peuvent produire et ont produit en effet dans l'espèce humaine, me font douter si divers animaux semblables aux hommes, pris par les voyageurs pour des bêtes sans beaucoup d'examen, ou à cause de quelques différences qu'ils remarquoient dans la conformation extérieure, ou seulement parceque ces animaux ne parloient pas, ne seroient point en effet de véritables hommes sauvages, dont la

race dispersée anciennement dans les bois n'avoit eu occasion de développer aucune de ses facultés virtuelles, n'avoit acquis aucun degré de perfection, et se trouvoit encore dans l'état primitif de nature."

Other writers, who have pleased themselves with describing what they call a regular gradation or chain of beings, represent man only as a superior kind of monkey; and place the unfortunate African as the connecting link between the superior races of mankind and the ourang-outang. (White's account of the regular gradation in man and animals, &c. 4to. London 1779.) The precise meaning of the word gradation, in this mode of employing it, we do not understand, nor do those who use it favour us with any definition of a term so very important in settling the question: we conceive the meaning to be that man is not a race originally distinct from monkeys. That the slave merchant, who traffics in human blood, and the negro-driver, who uses his fellow creatures worse than brutes, should endeavour to justify their conduct by depressing the African to a level with the brute, is what we might reasonably expect, as well as to hear the slave traffic commended because it imparts to the negroes the blessings of Christianity: but we should not have expected to find such opinions defended by the natural historian: and we shall not hesitate to assert that they are as false philosophically, as the moral and political consequences, to which they would lead, are shocking and detestable. We set out with this position, that man has numerous distinctive marks, by which, under every circumstance of roughness and uncivilization, and every variety of country and race, he is separated by a broad and most clearly defined interval from every other animal, even of those species which, from their general resemblance to the human subject, have been called anthropo-morphous. We cannot, indeed, by any means coincide with those moderns who have indulged their imaginations in painting a certain continuity or gradation of created beings; and who fancy they have discovered great wisdom of the creator, and great wisdom of the creation in this respect; that nature makes no leaps, but has connected the various objects of the three kingdoms with each other like the steps of a stair-case, or the links of a chain. The candid and unprejudiced observer must allow, that in the animal kingdom there are whole classes, as birds, and particular genera, as the cuttlefish, which cannot find a place in such a scheme of arrangement without a very forced and unnatural introduction: and again, that there are certain genera, as the coccus, where the two sexes are so different from each other, that the male and female must be separated, and occupy different parts of the scale in this artificial plan of gradation.

The completely unsupported assertions of Monboddoo and Rousseau only shew that they are equally ignorant of the structure and characters of men and monkeys, and that they know nothing of the laws, according to which the deviations of an animal from the original stock take place. We should not waste a moment in refuting what is not defended by a single proof. But the subject is important and very interesting, and we shall therefore consider at some length what are the specific characters of man.

In this part of our subject we shall have frequent occasion to mention the ourang-outang, and therefore think it necessary to observe, that two distinct species have been confounded under this common appellation. Linnæus, Buffon, and Erxleben, have not rectified this mistake, although Blumenbach had long ago pointed it out. The latter author, in his manual of natural history, describes, under the name of *simia troglodytes*, the animal of which Tyfon, in his anatomy of the pigmy, has given so excellent an anatomical

description. It is found in Angola, Congo, and the interior of Africa, and, as well as the following, reaches about the size of a boy eight years old. It is called chimpansee, and has been described by the names pongo, jocko, and barris. It is distinguished by its black hair and very large ears; and has a nail on the thumb of the hind hand. The *simia fatyrus* is the proper ourang-outang (which word, in the Malay language, means man of the woods), is found in the island of Borneo, and is the animal dissected by Camper. It has reddish-brown hair, and no nail on the thumbs of the hind hands.

Distinctions between Man and Animals.—The circumstances which distinguish man from other animals, may be considered under the divisions of 1, external conformation; 2, internal structure; 3, functions of the animal economy; 4, faculties of the mind; 5, diseases; 6, alleged, but not well-grounded differences.

1. *External Conformation; erect Stature.*—Under the first head we remark, as the most distinguishing peculiarity of man, his erect stature: that majestic attitude which announces his superiority over all the other inhabitants of the globe. He is the only being adapted by his natural formation to the upright position. Enslaved to their senses, and partaking merely of physical enjoyments, other animals have the head directed towards the earth: "quæ natura prona atque ventri obedientia finxit." Man, whose more elevated nature is connected to surrounding objects by moral relations, who can embrace in his mind the system of the universe, and follow the connections of causes and effects, boldly regards the heavens, and can direct his sight even into the itary regions.

"Pronaque cum spectent animalia cetera terram,
Os homini sublime dedit; cælumque tueri
Jussit; et erectos ad sidera tollere vultus."

In considering this distinction, it will be necessary for us to prove two points: 1, that the erect stature is suited to the organization of the human subject; 2, that it is peculiar to man.

Erect Attitude suited to the human Organization.—The former is clear from what we shall observe afterwards, concerning the arrangement of certain parts of the human frame; it is not less evinced by the invariable practice of all nations in all ages of the world. The individuals of no nation, even in the wildest state, have ever gone on all fours; and no animal has ever altered its gait. The chief support of this notion concerning the human subject being designed to support the body on four limbs, has been derived from the examples of children lost in woods and growing up in a wild state. Can we conceive any thing more widely removed from the natural condition of man than these wretched individuals? and might we not as well adopt any monstrous birth for a model of the human form, as draw our notions of attitude and way of life from these specimens? Moreover, if we look attentively into the most authentic accounts of these wild men, we shall find, that in the least suspicious instances they were erect; as for instance, Peter the wild boy (Blumenbach in Voigt's Magazin für Physik, &c. v. iv. pt. 3. p. 91. Monboddoo Ancient Metaphysics, v. iii. p. 57 and 367.), the girl described by Condamine (Histoire d'une jeune fille Sauvage; Paris, 1761, 12mo.), a man found in the Pyrenées (Leroy sur l'Exploitation de la Nature dans les Pyrenées, London, 1776, 4to. p. 8.); and the young savage of Aveyron (Historical Account of the young Savage of Aveyron, London, 12mo.) On the other hand, where they have been described as going on all-fours, many circumstances of a very suspicious kind will be detected in the narrative, as in the account

of the *juvenis ovinus Hibernus* of Linnæus: we cannot therefore help suspecting that Linnæus's *homo sapiens ferus* has no more claim to the epithet *tetrapus* than to that of *hirsutus*.

That the structure of the human body is adapted to the erect attitude, may be deemed so clear as to need no proof: but two respectable authors have defended the contrary paradox (Mofcati von der körperlichen wesentlichen unterschiede zwischen der Struktur der Thiere und der Menschen; Göttingen, 1771, 8vo. and Schrage in a Dutch Journal.)

Structure of the lower Limbs.—The support of the trunk upon the two lower limbs, and its being moved by the muscles of those limbs, lead us to expect great peculiarities in their structure. We find accordingly, that man is distinguished by the great length of the legs in comparison to the trunk and to the arms. Daubenton's assertion, that no animal but man has lower extremities equalling the trunk and head together in length, is nearly correct: (the kangaroo, jerboa, &c. form exceptions, but do not invalidate the assertion so far as regards our present purpose.) The hind limbs of the ourang-outang fall very far short of this proportion. This length of the legs, which is so convenient in our erect attitude, makes us altogether unfit for going on all-fours, as any person will immediately discern by making or observing a trial: the limbs in such an experiment must be thrown obliquely backwards, or the articulations held in a bent and very insecure position. Even children, before they can walk, in whom the lower limbs are comparatively shorter than in adults, crawl upon their knees, or else drag the lower extremities after them on the ground. The feet of man are much broader than those of any animal, and admit of being separated more widely from each other. The sources of the latter prerogative reside in the superior breadth of the human pelvis, and in the length and obliquity of the neck of the femur, which, by throwing the body of the bone outwards, disengages it from the hip-joint. The whole tarsus, metatarsus, and toes, rest on the ground in the human subject, and afford an ample base of support for the body. The simia and the bear have the end of the os calcis raised from the surface; while, on the contrary, it projects in man, and its prominent portion has a most important share in supporting the back of the foot: it is larger and more prominent in man than in any animal. The thigh-bone is straight, and its two condyles of equal length in the ourang-outang. The thigh is placed in the same line with the trunk in man; it always forms an angle with the spine in animals; and this is often even an acute one: the unsteadiness of the erect attitude, and the difficulty of maintaining the equilibrium under such an arrangement, are too obvious to need any particular explanation.

Not only the length, but also the remarkable strength of the legs, when contracted with the slender arms, clearly shew that the former are designed for supporting and moving the body. And here we may adduce a further argument drawn from the progress of ossification. The bones of the tarsus, and particularly the os calcis, ossify at an earlier period, and advance more rapidly in their development than those of the carpus. Very little strength of hand is required in the first years of life, while the feet, at the end of twelve months, begin to be employed in sustaining the body, and advancing it by progressive motion.

The Muscles.—The extensor muscles of the ankle joint, and chiefly those which form the calf of the leg, are very small in the mammalia, even in the genus simia. The peculiar mode of progression of the human subject accounts sufficiently for their vastly superior magnitude in man. By elevating the

os calcis, they raise the whole body in the act of progression; and, by extending the leg on the foot, they counteract that tendency, which the weight of the body has to bend the leg in standing. Hence Aristotle, and others after him, very justly observed, that true calves of the legs can be ascribed to man only. See GASTROCNEMIUS and MUSCLE, under the head of *Standing and walking*.

The extensors of the knee are much stronger in the human subject than in other mammalia; as their double effect of extending the leg on the thigh, and of bringing the thigh forwards on the leg, forms a very essential part in the human mode of progression. The flexors of the knee are, on the contrary, stronger in animals; and are inserted so much lower down in the tibia (even in the simia) than in the human subject, that the support of the body on the hind legs must be very insecure, since the thigh and leg form an angle, instead of being continued in a straight line.

Upper Limbs.—A very cursory inspection of the upper limbs will convince us, that, whether we regard the situation and mode of their connection to the trunk, or the direction and arrangement of the articulations throughout, they are entirely unsuited to the office of supporting the body, and as well calculated for the uses to which we put them, of seizing and holding objects, and thereby executing, besides all the processes of the arts, a thousand minute but most serviceable actions of constant recurrence. The arms, instead of falling perpendicularly under the anterior part of the trunk, are thrust outwards by the clavicles; the glenoid cavities of the scapulae, instead of being directed downwards, as in quadrupeds, look outwards: the elbows bend outwards, instead of forwards, &c.

Thorax.—The whole arrangement of the thorax shews man to be a biped. Those quadrupeds which have long legs, have a thorax compressed at the sides, narrow and keel-shaped in front, consequently deep from the spine to the sternum, but confined in the transverse dimension, and they are destitute of clavicles, so that the front legs come together, and support with greater firmness and facility the front of the trunk. They possess moreover a longer sternum, or a greater number of ribs (18 in the horse), which advance nearer to the crista of the os innominatum, for the purpose of supporting the abdominal viscera in the horizontal position of the trunk. Even in the ourang-outang, the measurement of the thorax from spine to sternum exceeds that from side to side. (*Œuvres de P. Camper. i. p. 115.*) All these particulars are different in man. His thorax is flattened in front, very broad, but shallow from before backwards: the humeri are thrown to the sides of the trunk, and thus acquire a more extensive range in their motions: the sternum is short, and the abdomen unprovided with bony supports in a very great share of its surface. These, with other points which cannot escape observation, when the skeleton of any rather long-legged quadruped is compared to that of man, shew how unfit he is for the attitude on all fours, which in his case can never be otherwise than unsteady, irksome, and fatiguing in the highest degree.

Pelvis.—The peculiarities of the human pelvis afford a strong confirmation of what we have already stated. The form of this part is very characteristic in man, and enables us to distinguish him from the anthropomorphic simia, and indeed from all the other mammalia. Although it might sound paradoxical and affected, yet we could defend the assertion that the human skeleton alone has a proper *pelvis*; that is, such a connection of the sacrum and coccyx with the ossa innominata, as forms a cavity resembling a basin; from which the elongated ossa innominata of other mammalia differ toto cœlo. In the ourang-outang and elephant we find the

nearest approach to the human formation: in the former, however, the upper part of the ileum is narrow and elongated, stretching upwards in the direction of the spine, and its length exceeds its breadth, so that the relations of these two dimensions are very different in man and this animal. The height of the whole pelvis, from the tuber ischii to the anterior spine of the ileum, is 7 in. 3 li. in man, and 6 in. in the ourang-outang; its breadth between the two anterior spines in the former 10 in. 6 li.; in the latter 6 in. 6 li.: in the latter the symphysis pubis is very deep: and in both, there is neither that incurvation of the sacrum from its promontory downwards, nor that direction of the coccyx towards the front, which, with the broad, horizontal expansion of the ilia, and the slenderness of the symphysis pubis are peculiar to the human frame, and constitute a broad and firm basis for the trunk, on which the weight of the abdominal contents is supported. The sacrum of the ourang-outang is flat and contracted, and continued in a straight line with the vertebral column.

Further Proofs.—Such then are the supports by which the trunk of the human body is firmly maintained in the erect position, and such are the properties of the trunk contributing to the same end. The breadth of the human pelvis affords a firm basis, on which all the superior parts rest securely; the same part is so narrow in other animals, that the trunk represents an inverted pyramid: there must consequently be great difficulty in maintaining it in a state of equilibrium, if it were possible for the animal to assume the erect position. In those instances where the pelvis is broader, the other conditions of the upright stature are absent: the bear, however, forms an exception to this observation, and consequently may be taught to stand and walk erect, although the posture is manifestly inconvenient and irksome to the animal. When quadrupeds endeavour to support themselves on the hind extremities, as, for instance, for the purpose of seizing any objects with the fore-feet, they rather sit down than assume the erect position. For they rest on the thighs as well as on the feet, and this can only be done where the fore-part of the body is small, as in the simia, the squirrel, &c.: in other cases the animal is obliged to support itself by the fore-feet also, as in the dog, cat, &c.

The perpendicular position of the vertebral column under the centre of the basis cranii, and the direction of the eyes and mouth forwards, would be as inconvenient to man, if he went on all fours, as they are well adapted to his erect stature. In the former case he would not be able to look before him; and the great weight of the head, with the comparative weakness of the extensor muscles, and the want of ligamentum nuchæ, would render the elevation of that organ almost impossible. See CRANIUM, under the head of "comparison of the human skull with that of animals," and HEAD.

Every part of the skeleton would lead to the same inference on this subject: but we forbear to enter into further detail, as being unnecessary. The reader will meet with some observations on this subject in the articles EXTREMITIES and MUSCLE.

The relation of the neighbouring soft parts to the pelvis deserves our consideration. Its posterior surface gives origin to the glutei muscles, of which the exterior (glutei magni), exceeding in size all others in the body, and covered by a remarkable stratum of fat, form the buttocks, which, by their ample, fleshy, and convex protuberances, conceal the anus, and are accounted, both by the classical authors in natural history, as Aristotle and Buffon, and by the greatest physiologists, as Galen and Haller, as the chief character by which man is distinguished from the buttocks of the simia. "Les fesses,"

says the great historian of nature, "n'appartiennent qu'à l'espèce humaine." The final cause of this prerogative has been assigned by an anatomist: "Solus homo ex omnibus animalibus commode sedet, cui carnosæ et magnæ nates contingere, et pro subternaculo pulvinarique, tomento repleto, inferviunt, ut citra molestiam sedendo, cogitationibus rerum divinarum animum recte applicare possit." Spigel. de Hum. Corp. Fab. p. 9.

The use of the glutei, however, is not confined solely to what the pious Spigelius has imagined, viz. the forming a cushion on which the body may be softly supported for the purposes of divine cogitation; but they are very important agents in extending the pelvis on the thighs, and maintaining it in that state in the erect position of the trunk. (See GLUTÆUS.) Thus the muscles are particularly connected with the attitude of man; and hence the gluteus maximus, which is the largest muscle of the human body, is so small and insignificant in animals, that it may be almost said not to exist. F. Cuvier says of the ourang-outang "les fesses étoient presque nulles, ainsi que les mollets." Annales du Muséum, t. 16. p. 47.

Direction of the Vagina.—The peculiar curvature of the human sacrum and os coccygis gives rise to the particular direction of the organs of generation, and especially of the vagina. That canal, which in the other female mammalia nearly follows the axis of the pelvis, is placed almost at right angles to that axis in the woman: hence parturition is more difficult; but many inconveniences, to which she would have been otherwise exposed, particularly during pregnancy, are obviated.

From this direction of the vagina we explain why the human female is not, like that of brutes, retromingent: and there is this further difference, that the orifice of the urethra in brutes, instead of being placed as in woman, within the labia pudendi, opens into the vagina itself: such at least is the case, according to Blumenbach, in the papio maimon, and simia cynomolgus.

The same circumstance concerning the direction of the vagina will enable us to determine the question agitated from the time of Lucretius, about the most natural posture for the act of copulation, "et quibus ipsa modis tractetur blanda voluptas."—"Quamquam enim," says Blumenbach, "non uno tantum modo sacra hæc celebrare possit homo, eademque cultus varietas a Latinobarbaris ad ea relata sit, quibus ipse a brutis differat, imo et physicæ causæ quandoque intercedere possint, quæ eundem more ferarum, quadrupedumque magis ritu concumbere suadeant; in unum tamen vaginæ ad virilem hastam relationem obversæ veneri magis adaptata videtur." The opinion referred to in this passage by Blumenbach is in the commentaries of Berenger of Carpi, on the anatomy of Mundinus, p. 13. "Homo inter cetera animalia coit per diversos situs, dando amplexus et oscula, et detestandus est in hoc, quia est magis vitiosum ac voluptuosum et diabolicum, quam rationale."

"Monkeys always copulate backwards: this is performed sometimes when the female is standing on all fours; and at other times the male brings her between his thighs when he is sitting, holding her with his fore-paws." Hunter on the Animal Economy, p. 136.

That we may finish at once what we have to observe concerning these organs of the female, we add a few remarks on the hymen, &c. It has been generally asserted that this membrane is found nowhere but in the human subject: but there are doubts on this point. (See GENERATION.) Blumenbach examined many animals of the genus simia, and a female elephant, without finding either hymen, or any thing like caruncule myrtiformes. It is a very singular part of the

the female frame, and one for which no rational use has been hitherto assigned. See GENERATION.

The nymphæ and clitoris, which have been supposed, like the hymen, to be peculiar to the human subject, are certainly found in many animals.

Man is a two-handed Animal.—From the erect attitude of man arises another very distinguishing prerogative; *viz.* the most free use of his two very perfect hands. So greatly does he excel other animals in the conformation of these parts, that Anaxagoras was hence induced to make an observation, which Helvetius has again brought forwards in our time, “that man is the wisest of animals, because he possesses hands.” This indeed is too much, yet Aristotle is well justified in observing that man alone possesses hands really deserving that name. Several genera of the mammalia possess hands; but they are much less complete, and consequently less useful than that of the human subject, which well deserves the name given to it by the Stagyræite, of the organ of all organs. The great superiority of that most perfect instrument, the human hand, arises from the size and strength of the thumb, which can be brought into a state of opposition to the fingers, and is hence of the greatest use in enabling us to grasp spherical bodies, and take up any object in the hand, in giving a firm hold on whatever we seize, in executing all the mechanical processes of the arts, in short, in a thousand offices, which occur every moment of our lives, and which either could not be accomplished at all, if the thumb were absent, or would require the concurrence of both hands, instead of being done by one only. All the simiæ possess hands: but the most distinguishing part, namely the thumb, is slender, short, and weak, even in the most anthropo-morphous: regarded as an imitation of the human structure, it would almost warrant the term employed by Eutachius, ridiculous: and the other fingers are elongated and slender. The thumb reached to the first articulation of the index in the ourang-outang described by F. Cuvier, *Annales du Muséum.* t. 16. p. 47.

Monkeys are four-handed.—The monkeys, apes, and other anthropo-morphous animals can, in fact, be called neither bipeds nor quadrupeds; but they are quadrumanous, or four-handed. Their posterior limbs are furnished with a thumb, instead of a great toe; which latter part belongs only to man, and arises from the manner in which his body is supported in the erect position.

By a thumb we mean a member, not placed in a parallel direction to the other fingers, but standing off from them laterally, enjoying a free power of separate motion, and, therefore, capable of being brought into opposition to the other fingers, so as to give to the member the power of grasping or prehension. A great toe, in its direction, articulations, and extent of motion, corresponds entirely to the other toes; whereas, the joints and muscles must be altogether different in the thumb. It is hardly necessary to point out how entirely unfit the human feet are for all purposes of prehension: but the hind limbs of the simiæ really deserve the name of hands more than the front; and are more advantageously constructed for holding. There is, too, a kind of monkey (*simia paniscus*, Linn. Coaita, Buff.) without any thumb to the fore limb; but no species has been discovered without the thumbs on the hind-limbs.

Hence the dispute concerning the mode of progression of the ourang-outang and other simiæ; *viz.* whether they go on all-fours, or are supported by the posterior limbs only, will be easily settled. Neither of these representations is correct. Since the hands of these animals are not formed for walking, but for seizing and holding objects, it is clear

that nature has designed them to live chiefly in trees. They climb these, and seek their food in them; and one pair of hands is employed in fixing and supporting the body, while the other gathers their food, or serves for other offices. Hence some, who have less perfect hands, are furnished with prehensile tails, by which they can be more securely supported in trees.

It is hardly necessary to add, that when we see monkeys walking erect, it is to be ascribed to instruction and discipline. The delineations of the ourang-outang, taken accurately from the life, shew how inconvenient and unnatural the erect posture is to these animals: they are drawn with the front hands leaning on a stick, while the posterior ones are gathered up into the appearance of a fist. No instance has ever been produced of a monkey, nor of any other animal, except man, which could preserve his body in a state of equilibrium, when standing on one foot only. All these considerations render it very clear, that the erect stature not only arises out of the structure and conformation of the human body, but also that it is peculiar to man: and that the differences in the form and arrangements of parts, derived from this source only, are abundantly sufficient to distinguish man by a wide interval from other animals.

Monkeys not constructed for the erect Attitude.—The circumstances in the structure of the monkey kind, which render them unsuited for the erect attitude, have been already in part explained: *viz.* the narrowness of the pelvis, short and weak lower limbs, small size of the muscles composing the buttocks and calves, and slight prominence of the os calcis, which does not come to the ground. We may add, that the exterior margin of the foot chiefly rests on the ground in the simiæ, which circumstance, while it leaves them a freer use of their thumb and long toes in seizing the branches of trees, &c. renders the organ so much the less adapted to support the body on level ground. The plantaris muscle, instead of terminating in the os calcis, expands into the plantar fascia, in animals of the monkey kind; and in other quadrupeds it holds the place of the flexor perforatus digitorum pedis, passing over the os calcis in such a direction, that its tendon would be compressed, and its action impeded if the heel rested on the ground.

It is rather singular, since persons have been found to contend that man ought to go on all-fours, that there should have been others, who undertake to prove, that the ourang-outang, and the monkey tribe in general, have an organization suited to biped progression. Buffon even states, that one which he saw always went on two feet, and he ascribes the erect attitude to him without any hesitation. We do not doubt that he can sustain this posture for some time, and when in the unnatural condition of confinement, he may frequently sit: hence, perhaps, we may account for the numerous observations in which he is said to go erect. But the circumstances of structure already explained, shew most clearly that he is not calculated, like man, for that attitude; and we find, in some of the most authentic accounts, that he is said to go on all-fours. Allamand, who saw one (*simia fatyrus*) in Holland, gives us the following account of its motions and attitudes. “Its usual attitude was sitting; with its thighs and knees raised; it walked nearly in the same posture, its rump being very near the ground. I never saw it perfectly upright, except when it wished to reach something; and even then its knees were always a little on the bend, and it tottered.” (Buffon, by Wood, vol. x. p. 79.) Vofmaer, who has described the same individual, says, “This animal generally walked on all-fours, like the other monkeys, but it could, likewise, walk erect on its hind feet, and, provided with a stick, it would often sup-

port itself for a considerable time. However, it never rested its feet flat on the ground, as a man would do, but bent backwards in such a manner, that it supported itself on the external edge of its hind feet, with the toes drawn inwards, which denotes a posture for climbing trees." (Ibid. p. 84.) The testimony of Camper, concerning one which lived for some time at the menagerie of the stadtholder at Petit Loo, is to the same effect: "L'orang vivant courait a quatre pattes, et lorsqu'il se tenoit debout (ce qu'il fit le plus, dans les premiers tems de son arrivee et lorsqu'il jouissoit encore de toute sa vigueur) il tenoit les genoux ployés." (Œuvres, tom. i. p. 60.) The bent knees, and general attitude of the figure represented by Tyson, shew clearly that the animal was not designed for a biped: "Being weak," says the author, "the better to support him, I have given him a stick in his right hand." (P. 16.) Several passages shew that this animal often went on all-fours, and thus concur with the representation given in the report of the directors of the Sierra Leone company, p. 164: in describing a young one, they say, "at first he crawled on all-fours, always walking on the outside of his hands; but when grown larger, he endeavoured to go erect, supporting himself by a stick, which he carried in his hand." The description of the individual observed by F. Cuvier, corroborates these observations: he climbed excellently, but walked as imperfectly. In the latter operation, he rested his closed hands on the ground, and dragged forward his hind parts. If one hand was held, he could walk on his feet; but then he supported himself partly by resting the other hand on the ground. The outer edge of the foot alone touched the ground, and the toes were bent. *Annales du Museum*, vol. xvi. p. 49.

That the gibbon (*simia longimana*), another of the anthropo-morphous *simiæ*, is not suited for the erect attitude, appears from the testimony of Daubenton. It could carry itself almost erect on its feet, but the legs and thighs were rather bent, and sometimes the hand touched the ground to support the reeling body; it was unsteady whenever it stopped while in an upright posture; it rested on the heel only, and raised the sole of the foot; it remained but a short time in this attitude, which appeared unnatural. (Buffon, by Wood, vol. x. p. 80.) We must, therefore, set down as incorrect the following assertion of Linnæus: "Dari simias erecto corpore binis æque ac homo pedibus incedentes, et pedum et manuum ministerio humanam referentes speciem."

The relative size of the cranium and face, the nearly vertical direction of a line drawn in front of the forehead and face, and the position and direction of the great occipital foramen and condyles, are points in which man differs from all animals. See CRANIUM.

Teeth.—The teeth of man are distinguished by the circumstance of their being arranged in an uniform, unbroken series: there are intervals, and some teeth project beyond the others in all animals. The canine teeth are longer than the others in monkeys; in some genera very considerably so; and there are intervals in each jaw to receive the teeth of the other. The lower incisors are placed perpendicularly, which is a principal characteristic of the human frame: the cuspidati neither project beyond the neighbouring teeth, nor are separated from them by any interval. The molares are clearly distinguished by their obtuse prominences from those of all the *simiæ*. The lower jaw is remarkable for three circumstances; viz its shortness, the prominence of the chin, which corresponds to the perpendicularity of the incisor teeth, and the form, direction, and articulation of the condyles. The lower incisors of man and the front of his

jaw are placed in the same vertical line: in animals the former slant very considerably backwards, the jaw slopes backwards directly from the alveoli, and there is consequently no chin.

Smoothness of the Skin.—Passing over some circumstances of less consequence, ordinarily enumerated among the distinctive characters of man, as the lobules of the ear, the tumid lips, particularly the inferior one, &c. we have a few remarks to make on the smoothness of the human integuments. "Dantur," says Linnæus, "alicubi terrarum simiæ minus quam homo pilosæ:" but he does not tell us in what part of the world they are to be found. The unanimous reports of all travellers, as well as the specimens of such animals exhibited in Europe, prove incontestibly that the man-like *simiæ*, called ourang-outangs, whether the species from Angola, or that from Borneo, as well as the long-armed monkey or gibbon, are naturally much more hairy than the human subject. Although the individuals brought into these countries have been under the adult age, and generally very sickly, their body has been in all cases universally hairy. We have, indeed, some accounts of people, particularly in the islands of the South sea, remarkable for their hairiness: but they are not completely satisfactory. Spangberg relates, that he found such a race in one of the Southern Kurile islands (lat. 43° 50'), on his return from Japan to Kamtschatka. (Müller Sammlung Russischer Geschichte, tom. iii. p. 174.) And J. R. Forster observed individual instances in the islands of Tanna, Mallicollo, and New Cædonia. (Observations on a Voyage round the World.) Such a race is said to be found in the interior of Sumatra. Mariden, History of Sumatra, p. 35, note.

While man is remarkable for the smoothness of his skin on the whole, some parts of his body are even more hairy than they are in animals, as, for example, the pubes and axilla, which the ancients consequently regarded as peculiar characters of man.

Comparative Proportions of the Body in Man and the Ourang-outangs.—To this division we shall subjoin a short statement of the comparative size of parts in the human subject and in the ourang-outangs: it is an important point in illustrating the specific differences of the two animals, and cannot be so conveniently introduced in any other part.

The difference of stature is remarkable: none of those hitherto brought into Europe has been more than three feet high, and most have been under that size. Of eight seen by Camper, none exceeded 2½ feet (Rhyland measure): (Œuvres, vol. i. p. 51.) From observing the state of the teeth, and progress of ossification, and estimating, according to the human subject, the additions which the stature might be expected to receive, he thinks that their adult height may be set down at 4 feet (Rhyland measure); and F. Cuvier makes it considerably less. (*Annales du Museum*, vol. xvi. p. 51.) Yet travellers speak of them as 5 and 6 feet high, and even more: what they say of their erect gait, of their violating women, &c. &c. is probably of equal accuracy.

Tyson's chimpanzee (*simia troglodytes*) was 26 inches from the top of the head to the heel: the arm, from the shoulder to the end of the fingers, 17 inches: the hand, 5½ inches: the middle finger 2½ inches. From the head of the thigh-bone to the heel, 12 inches: from the heel to the end of the middle toe, which was the longest, 5¾ inches. femur, 7: Tyson's Anatomy of a Pigmy, p. 15.

In the true ourang-outang (*S. fatyrus*), according to Camper, the whole length was less than 32 inches: the arm, 8½: the fore-arm, 9: the hand, 7: the fingers, 3: the femur, 7: the tibia, 7: the foot, 7½: the toes, 2¾.

In the ourang-outang described by F. Cuvier, the height was

was between 26 and 30 inches: the arm, from the axilla to the end of the fingers, measured 18: and the lower extremity, from the top of the thigh to the tarsus, 8 or 9. *Annales du Muséum*, vol. xvi. p. 46.

The important differences will be perceived by comparing these measures with the proportions of the human frame, as given in a former part of this article: we just place, in parallel lines, two or three of the most striking.

		In Man.	Ourang-outang.
Length of the whole body	-	8 heads.	6 heads.
Length, from the end of one middle finger to that of other, when the arms are extended	-	8 ———	8 ———
Length of the hand	-	$\frac{4}{5}$ ———	$1\frac{2}{5}$ ———
Length of the foot	-	$1\frac{1}{5}$ ———	$1\frac{1}{5}$ ———

In the following table we have placed together the dimensions of some parts of a male skeleton; of the *simia fatyrus* (ourang-outang, Camper); and of the *simia troglodytes*, (chimpanzee, Tyfon.)

	Man.	S. Satyrus. (Camper.)	S. Troglodytes. (Tyfon.)
	Inches.	Inches.	Inches.
The whole body	71	uncertain, } but less than } 30	26
Upper extremity	32	*24 $\frac{1}{2}$	17
Lower extremity	39	16	12
Hand - - -	8 $\frac{1}{4}$	7	5 $\frac{1}{2}$
Thumb - - -	4 $\frac{1}{4}$	1 $\frac{1}{4}$	1 $\frac{1}{4}$
Middle finger - -	4 $\frac{1}{4}$	3	2 $\frac{1}{2}$
Femur - - -	20	7	7
Tibia - - -	16 $\frac{3}{4}$	7	7
Foot - - -	10 $\frac{1}{2}$	7 $\frac{1}{2}$	5 $\frac{3}{4}$
Middle toe - -	2 $\frac{1}{4}$	2 $\frac{3}{4}$	1 $\frac{1}{2}$

* This length seems excessive: Camper's measures are, arm 8 $\frac{1}{2}$, fore-arm 9, hand 7. In another, rather smaller individual, the same parts measured respectively, 6 $\frac{1}{2}$, 6, and 5 $\frac{1}{2}$ inches. *Œuvres*, vol. i. p. 49.

The comparative lengths of the upper arm and fore-arm, exhibit also a striking difference in man and the monkey kind. In a male skeleton measuring 5 feet 8 inches, the os humeri was 13, and the ulna 9 $\frac{1}{2}$; in a living man of 5 feet 9 $\frac{1}{2}$ inches, these bones were respectively 14 and 11. In Tyfon's chimpanzee of 26 inches, the humerus was little more than 5, the ulna 5, and the radius 5 $\frac{1}{2}$: in a monkey of 2 feet 2 inches, the humerus was 4 $\frac{1}{4}$, the ulna 5.

Other Distinctions.—We may observe further, with respect to the comparison of man and the ourang-outangs, that one species of the latter (*fatyrus*) has no nail on the thumb of the hind hand; and the other (*troglodytes*), according to Tyfon, has 13 ribs. Both of them have a sacrum composed of three pieces only, instead of five, as in the human subject; and one at least (*fatyrus*) has a large membranous pouch communicating with the larynx. The ourang-outang has no ligamentum teres (Camper, l. c. p. 132.); it has a membranous canal running along the spermatic chord from the abdomen to the tunica vaginalis, as other monkeys and quadrupeds have (*ibid.* p. 109.); but this does not exist in the chimpanzee. (Tyfon, p. 82.) We venture to assert that these differences only, without any others, would be sufficient to establish the distinction of species: that no example can be adduced of animal structure deviating from its original model in this way; and consequently that the difference can be accounted for only by referring the animals to species originally distinct.

II. *Distinctions of Internal Structure.*

1. Parts that man alone, or with a few other mammalia does not possess. Most of these, which are found chiefly in the domesticated kinds, were formerly attributed to man, when human dissections were rare, from the want of opportunity, or greater attachment to zootomy.

The *Panniculus carnosus*, or subcutaneous stratum of fibres, described by Galen and his followers, even by Vesalius, the great restorer of anatomy, and exposé of Galen's errors, as a part of the human body, does not exist in man, nor, according to Tyfon, in the chimpanzee. It is found in the monkeys.

The *rete mirabile* of the head, the seventh or suspensorius muscle of the eye, the membrana allantois, and ligamentum nuchæ, are parts not found in the human subject.

The foramen incisivum is common to man with animals; but it is small and single: most other mammalia have it double and large.

On the subject of the intermaxillary bone, see the comparison of the human head with that of animals, in the article CRANIUM; and the article MAMMALIA, in *Comparative Anatomy*.

2. *Differences between Man and Animals, in certain internal Parts: the Brain.*—Passing over in silence some less important points, as, for instance, that the human crystalline is proportionally smaller than that of any animals, excepting the cetacea, and less convex in the adult, that the foramen occipitale is placed further forwards in the head (see CRANIUM), &c. we find in the brain a very striking difference between man and other animals. He has the largest brain, not, according to the opinion which has been generally received since the time of Aristotle, in proportion to the rest of the body, but to the size of the nerves, which proceed from it. Hence, if we divide the nervous system into two parts, one consisting of the nerves, and that part of the brain, from which they arise, which is to be considered as appropriated to the functions of a merely animal life; the other, comprehending the remainder of the brain, and connecting the functions of the nerves with the faculties of the mind, man will possess the greatest proportion of the latter more important part. See Soemmerring *Diff. de Basi Encephali*, p. 17. I. G. Ebel *Obf. Neurologicæ ex Anatome comparata Francof. ad Viadr. 1788.* Soemmerring *von der Körperlichen Verschiedenheit des Mohren vom Europäer*, 1785.

From the latter work of Soemmerring, to whom we owe the discovery of this very interesting circumstance, we extract his own account of the matter. "The careful and accurate comparison of the brains of animals of various orders, for which my opportunities have been very considerable, conducted me at last to the following position, first discovered by myself: 'that man possesses with the largest brain the smallest nerves;' or, that the assertion that man has the largest brain will hold good only in comparing that organ to its nerves. That acute physiologist Monro seems to be the first who adopted and confirmed this opinion. (On the Nervous System, Edinb. fol. chap. 8.) It was formerly conjectured, indeed assumed, that man has the largest brain; but how was this proved? by weighing the brain and the body in man, and in the most common domestic animals: thus far observation confirmed it. But those physiologists who carried their investigations further, were considerably perplexed at finding that birds exceed man in the proportion which their brain bears to the rest of the body, and that the dolphin, seals, and the smaller mammalia, as the mouse, squirrel, &c. have, in proportion to their small bodies, (but certainly

certainly not in proportion to their head and organs of sense, or to that part which the face forms, compared with the cranium.) a very large brain.

"It is a very loose mode of proceeding to compare the body, of which the weight varies so considerably according to fatigue, illness, emaciation, or embonpoint, with the brain, which is affected by none of these circumstances, and seems to remain constantly the same; an easier and much less deceptive comparison is that of the brain to its own nerves.

"I do not conceive that the nerves are related to this organ, as excretory ducts are to a gland; but I think it probable that a very small proportion of its mass is sufficient for their connection, so far as mere animal existence is concerned. Consequently, the being which possesses the greatest quantity of brain over and above this portion, will probably possess the greatest intellectual capacity. Man, who holds only a middle rank in respect to his bodily properties, is raised in this point of view far above other animals; he is the first of beings. All the *simiæ* (for I have been fortunate enough to procure specimens of the four principal divisions) come after him; for, although the proportion of their brain to the body, particularly in the small species with prehensile tails, is equal to that of man, their very large eyes, ears, tongue, and jaws, require a much larger mass of brain than the corresponding parts in the human subject; and if you remove this, the ratio of the brain to the body is much diminished.

"Animals of various kinds seem to me to possess a larger or smaller quantity of this superabundant portion of brain, according to the degree of their sagacity and docility.

"The largest brain of a horse, which I possess, weighs one pound seven ounces; the smallest human brain that I have met with in an adult, two pounds five ounces and a quarter. But the nerves on the basis of the horse's brain are ten times larger than in the other instance, although it weighs less by fourteen ounces and a quarter.

"But we are not hastily to conclude that the human species have smaller nerves than any other animal. In order that my ideas may be better understood, I shall state the following imaginary case. Suppose the ball of the eye to require 600 nervous fibrils in one instance, and 300 in another, though only half the size of the former; further, that the animal with 600 fibrils possesses a brain of seven, and that with 300 a brain of only five drams; to the latter we ought to ascribe the larger brain, and a more ample capacity of registering the impressions made on the organ of vision; for, allowing one dram of encephalon to 100 fibrils, the brain which is absolutely the least will have a superfluous quantity of two drams, while the larger has only one. That the eye, which is supplied with a double quantity of fibrils, may be a more complete organ of sense, will be readily admitted; but the remark is inapplicable to the subject in dispute." P. 59—67.

The brain of the monkey is easily distinguished from that of man, independently of its size and weight; Soemmerring found no less than fifteen visible material anatomical differences between the human brain and that of the common ape. Ibid. p. 77.

Soemmerring has also shewn that the earthy matter of the pineal gland does not exist in any animal besides man. He found it once in the brain of a deer, and Caldani informed Blumenbach that it did not exist in an old man, whom he dissected. De Gen. Hum. Variet. p. 44.

Other Parts.—The situation of the heart, which rests, not on the sternum, as in quadrupeds, but, according to the erect attitude of man, on the diaphragm, is peculiar. Its basis does not look towards the head, as in the former, but towards the dorsal vertebræ; while the apex is turned to the

left breast. There are very few mammalia, besides man, which have the pericardium fixed to the diaphragm.

The appendix vermiformis cæci belongs to the chimpanzee and ourang-outang, the gibbon according to Daubenton, the phascioma of New Holland, and man.

In addition to what we have said about female organs, the parenchyma of the uterus is unlike that of any animal; the texture of the placenta, the length of the chord, and the single umbilical vein are peculiar to man. The *vesicula umbilicalis*, found in all human conceptions before the fourth month, has been observed in no other animal.

3. *Functions of the animal Economy. Pliancy of the human Frame.*—The most important prerogative under this head, according to Blumenbach, is the softness and pliancy (*teneritudo et obsequiosa mollities*) of the cellular substance. Zinn observed that this tissue is more fine and tender in man than in any animal. To this circumstance Blumenbach ascribes the singular power of adaptation to every climate on the globe. "Uti ergo natura hominem respectu victus omnivorum fecit; ita respectu habitationis eum omnis soli et climatis (*παντοδατον*) esse voluit; ideoque corpus ejus ex maxime obsequioso contextu mucoso fabricatum est, ut eo facilius ad multifarios diversorum climatum impulsus se aptare et accommodare possit." De Gen. Hum. Variet. Nat. p. 48.

If we adopt this view, it will afford an answer to a question stated in the outset, whether the existence of men in such various climates can be ascribed to physical construction or reason? In what way do the Greenlanders, the Eskimau, and the Canadian employ remarkable talents or invention to protect themselves against the cold? they brave the winter with open breast and uncovered limbs, and devour their whales and seals drest, raw, or putrid. The negro is healthy and strong under a vertical sun, with the soles of his feet bare on the burning sands. The fox, the beaver, the marmot, and the hamster, dig dwellings for themselves: where then is the prerogative of man? The mind indeed employs the excellent structure of the body, lifts man above the rest of the creation, accommodates him to all places, gives him iron, fire, and arms, furs, and screens from the sun, &c. but with all this could never make him what he now is, the inhabitant of all climates, if he did not possess the most enduring and flexible body. The lower animals have no defence against the evils of a new climate, but the force of nature. The arts of human ingenuity furnish a defence to man against the dangers that surround him in every region. Accordingly we see the same nation pass into all the climates of the earth; reside whole winters at the pole; plant colonies beneath the equator; pursue their commerce, and establish their factories in Africa, Asia, and America: They can equally live under a burning and a frozen sky, and inhabit regions, where the hardiest animals cannot exist. Such great changes indeed ought not to be hazarded suddenly, and without precaution. The greatest evils that have arisen from change of climate, have been occasioned by the presumption of health that refuses to use the necessary precautions, or the neglect of ignorance that knows not what precautions to use. But when changes are gradually and prudently effected, habit soon accommodates the constitution to a new situation, and human ingenuity discovers the means of guarding against the dangers of every season, and of every climate. The superiority of man appears more striking, when we compare him to the animals which most resemble him in form and properties. The most anthropo-morphous *simiæ* inhabit only a few small southern districts and islands of the old world; are subject to numerous diseases, lose all their vivacity, strength, and natural character, and perish after lingering

lingering in a miserable way, when removed from their native abodes. An ourang-outang brought to Paris, never recovered the exposure to cold in crossing the Pyrenées, and died at the age of fifteen months, with most of the viscera "déforané et remplis d'obstructions." (Annales du Muséum, t. xvi. p. 53.) The monkies in general are confined within very narrow limits; they exist with difficulty in temperate countries, and can propagate only in warm climates. One which was impregnated in this country, and attended with all possible care, brought forth a young one, which died immediately. (Hunter on the Animal Economy, p. 137.) Probably the species could not be continued here, with all the aid of art; and it certainly could not be effected, if the animals were wild. When they are introduced into the north (indeed into the greater part) of Europe, and very carefully managed in their food, temperature, &c. they die very quickly, and, in almost all cases of diseased viscera, particularly the lungs.

Slow Development.—Other circumstances in the economy correspond with this power of adaptation; such are, the slow growth, long infancy, and late puberty of man. In no animal but man do the futures of the cranium close, or the teeth come out at so late a period; none is so long before it can support the body on the legs, before it arrives at the complete adult stature, and capacity for exercising the sexual functions. If we add to these circumstances, that man is not provided by nature with means of defence, and, consequently, requires assistance; and that his great distinctions, reason, and speech, are only germs, which are not developed of themselves, but are brought to maturity by extraneous assistance, cultivation, and education, we shall infer that he is designed, by nature, for social union. Such a condition appears more consonant to the structure, properties, and functions of our frame, even if it were not supported by the concurring voice of actual experience in all ages and nations, than the imaginary and most absurdly named "state of nature," of some philosophers. Rousseau, the great apostle of this doctrine, informs us, in direct words, that the state of nature never has existed; and he sets aside all facts as foreign to the question. With these admissions before us, we are required to believe that we have degenerated from our natural state; that speech, society, arts, inventions, sciences, agriculture, commerce, property, civil government, and inequality of conditions, have introduced all possible misery, and have debilitated our physical being; that we should live in the woods scattered and solitary to get food enough, protect life by flight and force, satisfy our desires and sleep. Buffon has reasoned so well on this subject, that we employ his words. "In this condition of nature, the first education requires an equal time as in the civilized state; for, in both, the infant is equally feeble, and equally slow in its growth; and, consequently, demands the care of its parents during an equal period. In a word, if abandoned before the age of three years, it would infallibly perish. Now, this necessary and long-continued intercourse between mother and child is sufficient to communicate to it all that she possesses: and though we should falsely suppose that a mother, in a state of nature, possesses nothing, not even the faculty of speech, would not this long intercourse with her infant produce a language? Hence a state of pure nature, in which man is supposed neither to think nor speak, is imaginary, and never had an existence. This necessity of a long intercourse between parents and children produces society in the midst of a desert. The family understand each other both by signs and sounds; and this first ray of intelligence, when cherished, cultivated, and communicated,

unfolds, in process of time, all the germs of cogitation. As this habitual intercourse could not subsist so long, without producing mutual signs and sounds, these, always repeated and gradually engraven on the memory of the child, would become permanent expressions. The catalogue of words, though short, forms a language, which will soon extend as the family augments, and will always follow, in its improvement, the progress of society. As soon as society begins to be formed, the education of the infant is no longer individual, since the parents communicate to it, not only what they derive from nature, but likewise what they have received from their progenitors, and from the society to which they belong. It is no longer a communication between detached individuals, which, as in the animals, would be limited to the transmission of simple faculties, but are institutions of which the whole species participates, and whose produce constitutes the basis and bond of society." Buffon, by Wood, vol. x. p. 30.

Some other Characters.—No other of the class mammalia enjoys so long a life as man in proportion to his size. As the duration of life is in proportion to the time spent in arriving at the full growth, there is every reason to suppose that the monkies will fall very far short of man in this respect: in this climate they are cut off so quickly, that we cannot form a judgment.

The celebration of the rites of Venus is not confined to any particular season of the year; although the author of a work "de Amore," dedicated to Joanna of Arragon, so highly celebrated for her personal charms, enquires why "ætatæ puellæ sint libidinosiores & amantiores; viri autem contra hyeme."

Nocturnal discharges of the feminal fluid are peculiar to man. See GENERATION, in the physiology of the male organs.

Menses.—The menstrual discharge is peculiar to women, and belongs to the whole sex in all countries: so that Pliny is right in regarding woman as the only "animal menstruale." "I know indeed," says Blumenbach, "that the same discharge has been ascribed to other animals, particularly of the order quadrupana. I have carefully enquired about all the female monkies, which I have seen for these twenty years, either in menageries or carried about for public exhibition, and have found some of them liable to uterine hæmorrhage, which observed no period, and was regarded by the more intelligent keepers as a circumstance arising from disease, although they acknowledged, that in order to excite the admiration of the spectators, they often represented it as true menstruation." De Gen. Hum. Var. note, p. 51.

4. *Faculties of the Mind: Reason.*—All philosophers refer with one accord to the enjoyment of reason, as the chief and most important prerogative of the human species. If we enquire, however, more particularly into the meaning of this word, we shall be surprized to find what various senses different individuals affix to the same expression, or, as Blumenbach observes, "quam longe diversissimas de rationis notione reddunt rationes philosophi maxime rationales." According to some, reason is a peculiar faculty of the mind, belonging exclusively to man: others consider it as a more enlarged and complete development of a power, which exists, in a less degree, in other animals: some describe it as a combination of all the higher faculties of the mind; while others assert that it is only a peculiar direction of the powers of the human mind, &c. "Non nostrum inter hos tantas componere lites."

The subject may perhaps be more shortly and safely dispatched by considering it a posteriori. In the enumeration of natural existences we are obliged to rank man in the

class of animals : but the analogies on which we do this are external, and authorize us not to pronounce that the nature of man is similar to that of the brute. In order to acquire a distinct idea concerning the nature of each, it is necessary that we should have as complete a knowledge of the internal qualities of animals, as we have of our own. But, as it is impossible to know what passes within them, or how to rank and estimate their sensations, in relation to those of man, we can only judge by comparing the effects which result from the natural operations of both.

Let us, therefore, consider these effects ; and, while we acknowledge all the particular resemblances, we shall only examine some of the most general distinctions. The most stupid man is able to manage the most alert and sagacious animal : he governs it, and makes it subservient to his purposes. This he effects not so much by strength or address, as by the superiority of his nature. He compels the animal to obey him, by his being possessed of reason, which enables him to project and to act in a systematic manner. " *Quisquis es, iniquus æstimator fortis humanæ, cogita quanta nobis tribuerit parens noster, quanto valentiora animalia sub jugum miserimus, quanto velociora assequamur, quam nihil sit mortal non subicū nostro positum.*" Seneca. The strongest and most sagacious animals have not the capacity of commanding the inferior tribes, or of reducing them to a state of servitude. The stronger, indeed, devour the weaker : but this action implies an urgent necessity only, and a voracious appetite, qualities very different from that which produces a train of actions all directed to one common design. If animals be endowed with this faculty, why do not some of them assume the reins of government over others, and force them to furnish their food, to watch over them, and to relieve the sick or wounded ? But, among animals there is no mark of subordination, nor the least trace of any of them being able to recognize or feel a superiority in his nature above that of other species. We should therefore conclude, that all animals are of the same nature, and that the nature of man is not only far superior, but likewise of a very different kind from that of the brute.

Man uses all kinds of food, and inhabits every climate of the globe. The unlimited power, which he possesses in these respects, gives rise to various wants, from the infinite variety of climate, soil, and other circumstances.

Pater ipse colendi

*Haud facilem esse viam voluit, primusque per artem
Movit agros, curis aciens mortalia corda.*

Man receives, therefore, from his creator the power of invention and reason, which supply his wants. Hence, in the most ancient times, and by the wisest nations, the genius of invention has been honoured with divine worship : it forms the Thoth of the Egyptians, the Hermes of the Greeks. Thus, to give a few instances, man has made tools for assisting his labour ; and hence Franklin sagaciously defined him a "tool-making animal;" he has formed arms and weapons ; he has devised various means of procuring fire. Lastly, "the most noble and profitable invention of all others was that of speech, whereby men declare their thoughts one to another for mutual utility and conversation ; without which, there had been amongst men neither commonwealth ; nor society, no more than amongst lions, bears, and wolves." (Hobbes' *Leviathan*.) This is a most important characteristic of man, since it is not born with him, like the voices of animals, but has been framed and brought into use by himself, as the arbitrary variety of different languages incontestably proves ; or, as some conceive, with extraordinary assistance. See LANGUAGE.

Man exhibits, by external signs, what passes within him : he communicates his sentiments by words ; and this sign is universal. The savage and the civilized man have the same powers of utterance ; both speak naturally, and are equally understood. It is not owing, as some have imagined, to any defect in their organs, that animals are denied the faculty of speech. The tongue of a monkey is as perfect as that of a man : Camper asserts that the laryngeal pouch renders it impossible for the ourang-outang to speak ; we do not understand how this is ascertained ; but, allowing its truth, there are other monkeys who have no pouch, and yet cannot speak.

There are infinite subtleties both in the ancient and modern scholastics concerning the speech of brutes. We cite, as an example, Albertus, surnamed the Great, who allows to a monkey the privilege of speech, but with a memorable restriction : "*Pygmæus loquitur quidem, cum tamen sit irrationabile animal, verum non disputat ; nec loquitur de universalibus rerum, sed potius suæ voces diriguntur ad res particulares de quibus loquitur.*"

Several animals may be taught to pronounce words, and even to repeat sentences ; which proves clearly that the want of speech is not owing to any defect in their organs ; but to make them conceive the ideas which these words express, is beyond the power of art. They articulate and repeat like an echo or machine.

Language implies a train of thinking ; and for this reason brute animals are incapable of speech . for though we should allow them to possess something similar to our first apprehensions, and to our most gross and mechanical sensations, it is certain that they are unable to form that association of ideas in which alone the essence of thought consists. They can neither think nor speak, because they can neither join nor separate ideas ; and, for the same reason, they neither invent nor bring any thing to perfection.

With the operations of animals, who always perform the same work in the very same manner, the execution of any individual being neither better nor worse than that of any other, in whom the individual, at the end of some months, is what he will remain through life, and the species, after a thousand years, just what it was in the first year ; contrast the results of human industry and invention, and the fruits of that perfectibility, which characterises both the species and the individual : by the intelligence of man the animals have been subdued, tamed, and reduced to perpetual slavery. By his labours marshes have been drained, rivers confined, their cataracts effaced, forests cleared, and the earth cultivated. By his reflexion, time has been computed, space measured, the celestial motions recognized and represented, the heavens and the earth compared, and the Creator worthily adored. By his art, which is an emanation of science, the seas have been traversed, and mountains overcome ; nations have been united ; a new world has been discovered ; a thousand other detached lands have been reduced under his dominion ; lastly, the whole face of the earth at present exhibits the works of his power, which, though subordinate to that of nature, often exceeds, at least, so wonderfully second her operations, that, by the aid of his hands, her whole extent is unfolded, and she has gradually arrived at that point of perfection and magnificence in which we now behold her.

In the point of view which we have just considered, man stands alone ; his reason, and what he has effected by it, place him at a wide interval from all animals ; at an interval, which no animal hitherto known to us can fill up. The man-like monkey, the almost reasonable elephant, the docile dog, the sagacious beaver, the bee have no reason. In

none of these instances is there any progress either in the individuals or the species. See the article *INSTINCT*.

Laughter and Weeping.—Whether these are peculiar to man may admit of some doubt; they were not, like speech, invented by him, but seem rather born with him, and are more connected with the passions than with reason. Many animals secrete tears; but the question is, do they weep from grief? The fact has been asserted by some respectable witnesses, as by Steller of the seal, and Pallas of the camel. It is more doubtful whether they manifest mirth by laughter, though this has been asserted. Le Cat says, that he saw the chimpanzee both laugh and weep.

5. *Diseases*.—There are many diseases peculiar to man, which may be thought a more fit subject for pathology than natural history; but as these unnatural phenomena arise out of the natural organization and habit of the body, and dispositions of the animal economy, they undoubtedly deserve a place in the discussion.

While the causes of disease in general are so obscure, it is hazardous to set down any particular affections as exclusively belonging to man; they might affect other animals also, if they were exposed to the same causes. Wild animals, we believe, have no diseases; domesticated ones have several; and they are more numerous in proportion as the subjugation is more complete, and the way of life differs more widely from the natural one. The diseases of our more valuable domestic animals, are sufficiently numerous to employ a particular order of men; and the horse alone has a set of surgeons or physicians to his own share. The miserable canary birds seem to be equally in want of professional assistance: among the disorders to which they are exposed, Buffon enumerates inflammation of the bowels, asthma, epilepsy, abscess, shankers on the bill, and scabs. (Vol. xiv. p. 87.) In man, the most artificial of all animals, the most exposed to all the circumstances that can act unfavourably on his frame, diseases are the most numerous, and so abundant and diversified, as to exercise the ingenuity of the nosologist, and fatigue the memory of the physician. Perhaps nosological catalogues afford the most convincing proof, that man has departed from his natural habits, or has deserted that way of life to which nature had destined him; unless, indeed, it should be contended that these afflictions are a part of his nature, a distinction from animals of which he will not be very likely to boast. This, however, we apprehend, will be too much even for the sons of Galen to defend, and it would certainly bring the theologians on their backs, as leading to inferences not very favourable to the benevolence of the Deity. The following sentiments of a most eloquent writer, and great philosopher, deserve attention, although he was no physician. "Have we any solid reason to suppose, that in countries where medicine is most neglected, the life of man is shorter than where this art is the most carefully cultivated? And how should it be so, if the evils we bring on ourselves are more numerous than the remedies which medicine furnishes. The extreme inequality in the mode of living, the excessive labours which consume the bodies and break down the spirits of the poor, the still more dangerous softness, which enfeebles the rich, destroying the one by their wants, and the others by their excess; the ease with which sensuality can be excited and gratified, the too luxurious food of the rich, the monstrous mixtures, the pernicious seasonings which stimulate and overwhelm them with indigestion; the bad and often insufficient nourishment of the poor; the spoiled provisions, the sophisticated drugs; the knavery of those who sell, the errors of those who administer them; the want of rest, the violent passions which agitate and ex-

haust us, the chagrins and vexations incidental to all conditions; are so many fatal proofs that most of our ills are our own work, and might have been avoided by adhering to the simple, uniform, and solitary life prescribed by nature. If she designed that we should be healthy, I would almost affirm that reflection is a state contrary to nature, and that the man, who meditates, is already a depraved animal. Consider the epidemic diseases engendered among multitudes collected together, the disorders caused by the delicacy in our mode of living, by passing from our heated rooms into the open air, by increasing or lessening our clothing without sufficient precaution, and all the cares converted by our excessive sensuality into necessary habits, and the neglect or privation of which then very frequently costs us our life or health; add to the account the fires and earthquakes, which consume and overturn whole cities, and sweep off the inhabitants by thousands; in short, bring together the dangers, which all these causes constantly suspend over our heads, and you will feel how dearly nature makes us pay for despising her lessons. When we reflect on the healthy constitutions of savages, at least of those whom we have not corrupted by our spirituous liquors, and remember that they know no other ailments than wounds and old age, we are led to suppose, that the history of disease would be easily written by following that of civil societies." *Discours sur l'Inégalité*, p. 69, and note 8.

The history of the young savage of Aveyron strikingly illustrates several of the foregoing remarks. In his wild state, he bore the cold of the severest winter without any clothing, and could remain, when he was first taken, for several hours together, in the winter, exposed half naked to wind and rain on the wet turf. He refused high-seasoned dishes and strong liquors, even when very hungry, and ate at first only potatoes, acorns, and raw chestnuts. His civilization went on so rapidly and successfully, that in a few months he had had three severe colds, and soon after became subject to epileptic fits. An observation of Humboldt tends to confirm the position, that the individuals, whose bodies are strengthened by healthy habits in respect to food, exercise, &c. are enabled to resist those causes which produce diseases in other men. Humboldt paints to us the Indians of New Spain as a set of peaceful cultivators, accustomed to uniform nourishment, of an almost entirely vegetable nature, that of their maize and cereal gramina: they are subject to no deformity: he never saw a hunch-backed Indian, and it is extremely rare to see any who squint, or are lame in the arm or leg. "In the countries where the inhabitants suffer from the goitre, this affection of the thyroid gland is never observed among the Indians, and seldom among the Mestizos." (*Political Essay on the Kingdom of New Spain*, book ii. ch. 6.) Similar observations on the freedom from deformity occur in the descriptions of most savages.

This comparison of diseases is difficult, since the nosology of brutes must by its very nature be cultivated under the most serious obstacles. The diseases in the following list, derived from Blumenbach, may be considered, in all probability, as peculiar to man.

Nearly all the exanthemata, at least

*Variolæ**,
Morbilli,
Scarlatina,
Miliare,
Petechiæ,
Pestis.

* A monkey at Amsterdam, contracted a local ulcer from the contagion of small-pox, but had no fever.

Of the Hæmorrhagies.

Epistaxis,
Hæmorrhoides,
Menorrhagia.

Of nervous affections.

Hypochondriasis,
Hysteria,
Mental affections, properly so called, as *melancholia, nymphomania,*
gla, &c. probably also *satyriasis* and *nymphomania,*
Cretinismus.

Of the cachexiæ,

Rachitis,
Scrofula,
Lues Venerea,
Pellagra,
Leprosia and *Elephantiasis.*

Of the Locales.

Amenorrhœa,
Cancer,
Clavus,
Hernia congenita?

The various kinds of *prolapsus*, particularly that congenital one of the urinary bladder.

Herpes,
Tinea capitis.

6. In the preceding remarks, we have adverted to some of the points, in which man has been erroneously supposed to differ from animals: a few only remain. The approximation of the two eyes is not peculiar; they are much nearer to each other in the simia.

Many other mammalia, particularly among the quadrumana, have eye-lashes in both eye-lids: this is the case in the elephant.

The long-nosed monkey (*simia rostrata* or *nasalis*) exceeds man in the length of the nose.

The external ears are not immoveable in all men, nor moveable in all other mammalia, as in the ant-eaters for example.

Many quadrumana have an organ of touch, and an uvula, as well as man.

Varieties of the human Species.—Our next point is the consideration of the varieties of the human species, and their causes.

The differences which exist between inhabitants of different regions of the globe, both in bodily conformation and in the faculties of the mind, are so striking, that they must have attracted the notice even of superficial observers. There are two ways of explaining these: first, by referring the different races of men to different original families, according to which supposition they will form in the language of naturalists, different species; or we may suppose them all to have descended from one family, and account for the diversity, which is observable in them, by the influence of physical and moral causes; in which case they will only form different varieties of the same species.

This disquisition will perhaps appear superfluous to the devout believer, whose philosophy on this point will be derived from the writings composed with the assistance of divine inspiration, and therefore commanding our implicit assent. The account of the creation of the human race, and of its dispersion over the face of the globe, contained in the book of Genesis, will supersede in his mind the necessity of having recourse to any argument on the subject. We shall venture to submit, that the Mosaic account does not make it quite clear that the inhabitants of all the world descended from Adam and Eve: we are told indeed, that "Adam called his wife's name Eve, because she was the

mother of all living." But in the first chapter of Genesis we learn, that God created man, male and female; and this seems to have been previously to the formation of Eve, which did not take place until after the garden of Eden had been made. Again, we are informed in the fifth chapter of Genesis, that "in the day that God created man, in the likeness of God made he him; male and female created he them; and blessed them, and called their name Adam, in the day when they were created." We find also that Cain, after slaying his brother, was married, although it does not appear that Eve had produced any daughters before this time. "Cain went out from the presence of the lord, and dwelt in the land of Nod, on the east of Eden. And Cain knew his wife, and she conceived and bare Enoch." Indeed it is said (ch. 5, v. 4.), that "the days of Adam, after he had begotten Seth, were eight hundred years, and he begat sons and daughters." This it should seem took place after the birth of Seth, and consequently, long after Cain had his wife; for Seth was not born till after the death of Abel. If Cain had sisters prior to that period, from amongst whom he might have taken a wife, it is singular, as some persons may allege, that Moses should not have noticed them. But we refer the solution of these difficulties to the biblical critic and commentary, in whose judgment they will not materially affect the general credibility of the Scripture history.

It appears, therefore, that the field is open for discussion on this subject; and at all events, if the descent of mankind from one stock can be proved independently of the holy writings, the conclusion will establish the authority of these inspired annals.

If we fail in tracing the succession of the human race from above downwards, much less are we able to trace back any particular tribe to their first origin from the present stock. To use the words of an elegant modern historian; "neither the annals nor traditions of nations reach back to those remote ages, in which the different descendants of the first pair took possession of the different countries where they are now settled. We cannot trace the branches of this first family, nor point out with certainty, the time and manner in which they divided and spread over the face of the globe. Even among the most enlightened people, the period of authentic history is extremely short, and every thing prior to that period is fabulous and obscure." In considering the present question, we must, therefore, be contented to proceed in the slow and humble, but sure method of observation; to ascertain carefully all the differences that actually exist between the various races of men; to compare these with the diversities observed among animals; and to draw our inferences concerning the causes from the analogies which these considerations may unfold. Above all things, we must enter our protest against arguments *à priori* on this subject. One philosopher tells us, that nature does nothing in vain; that she would not give herself the trouble to create several different stocks, when one family would be sufficient to colonise the world in a short space of time. Another, with equal speciousness, dilates on the absurdity of supposing, that immense regions should remain for ages an unoccupied and dreary waste, while the offspring of a single pair was slowly extending over the face of the earth; or that such an admirable variety of islands should display their charms in vain, till a shipwreck or some other casual occurrence may supply them with inhabitants. He shews how much more consonant to the wisdom and benevolence of the Deity it would be, for the earth to have teemed, from the first moment of its production, with trees and fruits, and to have been occupied by all kinds of animals

mals suited to each soil and sky. We cannot too strongly express our reprobation of such idle declamation, which, by withdrawing our attention from the right method of investigation, inevitably tends to perpetuate our ignorance of nature. Dr. Prichard, the author of an excellent inaugural discourse on this subject, has so well exposed the futility of such arguments, that we present our readers with his own words. "Hæc quanquam satis speciosa, videantur, omnia ut sit plerumque in hujusmodi argumentationibus fluxa et incerta sunt. Qui magna loquuntur tanquam ipsi ex Dei concilio descendissent, neque ut humiles munitros, et naturæ interpretes oportet, raro lumine quantumcunque ejus abdita illustrant. Illi quidem dixerunt quomodo mundum constituissem, si hoc eorum curationi fuisset commissum; sed qua ratione re ipsa constitutus sit, talibus auspiciis, et latet, et semper latebit." P. 5.

What is Species?—Before we proceed to the chief object of this division of our article, it is necessary to consider what constitutes a species in zoology; and how varieties arise out of species. We should answer, in the abstract, to the first question; that all animals, which differ in such points only as might arise in the natural course of degeneration, belong to the same species; while those differences, which could not be accounted for on this supposition, would lead us to class the animals, which exhibit them, in different species. But the chief difficulty, is to point out the characters, by which, in actual practice, we can distinguish mere varieties from genuine specific differences.

Of Breeding as a Criterion of Species.—In the sixteenth century, and consequently long before the time of Buffon, Ray referred to one and the same species those animals which copulated together, and produce a fertile offspring, ascribing the differences which may exist between them to adventitious causes. The high authority of the great French naturalist, who adopted the same opinion, has occasioned this criterion to be very generally relied on; Mr. Hunter, on the faith of it, included the dog, the wolf, and the jackal in one species, and excluded the fox. If we adopt this, our present question would be immediately solved; for all the races breed together, and their progeny is prolific, either with each other, or with any of the original races. Indeed we know no difference in productiveness between such unions and those of the same race.

We apprehend that this rule involves a *petitio principii*; has it been proved, that animals of distinct species never produce together a fertile offspring? on the contrary, there are instances, both among the mammalia and birds, of individuals belonging to species universally held to be distinct, uniting and producing young, which were prolific. That the mule can engender with the mare, and that the she-mule can conceive, was known to Aristotle. The circumstance is said to occur most frequently in warm countries, but it has happened in Scotland. (Buffon, vol. iv. p. 200. 205.) The offspring of the he-goat and ewe seem to possess perfect powers of reproduction. The cock and hen canary birds produce with the hen and cock fish and goldfinch (ibid. v. xiv. p. 63, et seq.): the hen canary produces with the cock chaffinch, bullfinch, yellow-hammer, and sparrow. The progeny in all these cases is prolific, and breeds not only with both the species, from which they spring, but likewise with each other. (Ibid. p. 70.) It appears also that the common cock and the hen partridge, as well as the cock and the guinea-hen, can produce together. (Ibid. v. xii. 61.) It is true, that all these unnatural unions take place in animals under the power of man, and that they generally require an attention to several preliminary circumstances: it is also found that unions of different species may take place without fecundation, as of the bull and

mare (Buffon, v. iv. p. 221.): but they prove sufficiently, that this affair of generation will not afford the criterion we are in search of.

It was soon found that this rule of reproduction could not be applied to domesticated animals, on account of their unnatural way of life, and hence Frisch, towards the beginning of the last century, confined it entirely to the wild ones. And here it is of little service; for how can we expect ever to bring together those wild species, particularly where they inhabit different countries, as for instance the chimpanzee of Angola and the ourang-outang of Borneo? Nor are there so many doubts about these, as about the domesticated animals, which are thus excluded.

The different breeds of dogs, for example, are referred by some to different species: others consider, that they have all descended from the shepherd's dog; others derive them from the jackal; and all the dogs with the latter animal, owe their origin, according to others, to the wolf.

Of other Marks.—Nor is the constancy of any particular character to be deemed a mark of difference in species. The white hair and red pupils of the white variety of the rabbit are as constant as any specific characters; and we see breeds of animals, produced under our own eyes, distinguished by marks transmitted regularly to the offspring.

The Criterion of Analogy.—We must therefore resort to the criterion adopted by Blumenbach, and draw our notions of species in zoology from analogy and probability. (De Gen. Hum. Variet. Nat. p. 70.) If we see two races of animals resembling each other in general, and differing only in certain respects, according to laws, which we have found to hold good in other instances, we refer them to the same species without hesitation. "I see" says this most acute and judicious naturalist, "a remarkable difference between the Asiatic and African elephants in the structure of the molar teeth. Whether these inhabitants of such distant regions will ever be brought to copulate together, and whether this formation be universal is uncertain; but it exists in all the specimens I have seen or heard of, and I know no example of molar teeth changed in such a manner by degeneration (or the action of adventitious causes): therefore, I conjecture from analogy, that these elephants are not mere varieties but truly different species. On the other hand, I hold the ferret (*m. putorius*), not so much because they produce together, but because it has red pupils, and the analogy of numerous other instances induces me to regard all the mammalia, which are destitute of the colouring pigment of the eye, as varieties degenerated from their original stocks."

It is very clear that this analogical method is the only one that we can adopt for solving the question concerning the varieties of the human species; we must explain the bodily diversities of man upon the same principles, as those of all other domestic animals; and if we find these causes adequate to the solution of the phenomena, it will be unnecessary to resort to the supposition of originally different species.

A very superficial consideration will shew, that there is no point of difference between the several races of mankind, which has not been found to arise, in at least an equal degree, among other animals as a mere variety, from the usual causes of degeneration. The instances of this kind are derived chiefly from domesticated animals, as they are exposed to all those causes which can produce such effects; by living with man they lead an artificial and unnatural kind of life, and are taken with him into climates and situations, and exposed to various other circumstances altogether different

from their original destination; hence they run into numerous varieties of colour, form, size, &c. which, when they are established as permanent breeds, would be considered by a person uninformed on these subjects, to be originally different species. Wild animals, on the contrary, remaining constantly in the state for which they were originally framed, retain permanently their first character. Man, the inhabitant of every climate and soil, partaking of every kind of food, and of every variety in mode of life, must be exposed still more than any animal to the causes of degeneration.

Differences of Colour.—The various colours of the skin form very constant hereditary characters, most clearly influenced by that of both parents in the hybrid offspring of different varieties, having a close and nearly uniform relation to that of the hair and iris, and indeed to the whole temperament of the individual; and for all these reasons attracting most immediately the attention of a cursory observer.

The seat of this colour is in a thin mucous stratum, interposed between the cuticle, or dead surface of the body, and the true skin, and called rete mucosum or Malpighii. The native reddish white of the real skin appears through this, which is very thin and almost colourless, in the white races of mankind. But in the darker varieties the rete mucosum is much thicker, and contains throughout its substance a black pigment; while the cuticle and cutis deviate but little from the colour which they have in fair persons. See INTEGUMENTS.

The different varieties of mankind exhibit every possible shade between the snowy whiteness of the Albino or of the most delicate European female and the jet black of the Negro. Although none of these gradations obtain so universally, as to be found in all the individuals of any particular nation, nor are so peculiar to one race, as not to occur occasionally in other widely different ones, the national varieties of colour may be referred on the whole, with sufficient accuracy, to the five following principal classes:

1. White, to which redness of the cheeks is almost wholly confined, being observed at least very rarely, if at all, in the other varieties. This obtains in most of the European nations, in the western Asiatics, as the Turks, Georgians, Circassians, Mingrelians, Armenians, Persians, &c. and in the inhabitants of the north of Africa.

Considerable variety, however, will be found to exist in the colour known by the general epithet white. That singular race of men, the Albinos, possess a milk-white or red skin and yellowish-white hair, with red eyes. In the natural history of our species they have not met with much better treatment than the poor Negroes; for some have doubted whether they, as well as the latter, belonged to the same species with us. The Negroes were thought to be too black, the Albinos too white. Their skin has an unnatural whiteness, often seeming to approach to a slight degree of lepra, and the hair of all parts of the body has the same character. The latter has not the snowy whiteness of old age, nor the elegant light yellow or flaxen appearance of the fair-haired in our climates (blondins, Fr.) but is rather to be compared to the appearance of cream; neither is the colour of the skin like that of the European, but it approaches to that of milk, or of a white horse. The eye is deprived of its colouring matter; and hence the iris is of a pale rose colour, and the pupil intensely red, in consequence of the blood contained in the numerous vessels, which almost entirely make up the substance of those parts. Thus, the colouring matter of the body, as well that of the skin (rete mucosum), and hair, as that of the eye, (pigmentum nigrum, or more properly fuscum) is deficient.

These affections of the skin and eye are always concomitant. This peculiarity always exists from the time of birth; it never changes afterwards, and it is sometimes hereditary. The notion, that Albinos are incapable of propagation, is completely unfounded. They are in truth not numerous enough for them to breed together, and thus produce a permanent variety; but there are scattered instances to shew, that they can beget and conceive. A white negress bore a perfect negro to a negro father; and another produced with an European father three true Mulattoes, but with light hair. Blumenbach *Beiträge zur Naturgeschichte*, p. 125. See ALBINOS, EYE, under the description of the *Iris*, and INTEGUMENTS.

This variety was first observed in the African, as the great difference of colour would render the variation more striking: and hence the individuals were termed *Leucæthiopes* or white negroes; their peculiar constitution, for the deviation is by no means confined to the surface of the body, may be conveniently termed, after some modern authors, *Leucæthiopia*. From their avoiding the light, the Dutch gave them (in the island of Java) the contemptuous appellation of *Kakkerlakken* (insects shunning the light); the Spaniards called them *Albinos*, and the French *Blafards*. So far is this variety from being peculiar to the Negro, or even to the torrid zone, that there is no race of men, nor any part of the globe, in which it may not occur. Blumenbach has seen sixteen examples of it in various parts of Germany, and he refers to authors who have seen it in Denmark, England, Ireland, France, Switzerland, Italy, the Grecian Archipelago, and Hungary; in Arabia, on the coast of Malabar, in Madagascar, among the Caffres and Negroes, (as well those born in Africa, as the descendants of the individuals conveyed to America); in the isthmus of Darien and Brazil; in the islands of the Indian ocean and of the Pacific. *De Gen. Hum. Variet. sect. iii. § 78.*

There is another description of men with a very white skin, and often a rosy tint, particularly in the face, with yellow (flaxen) or red hair, and generally blue or whitish eyes (iris). The Germans, and nations descended from them, are of this kind.

Lastly. There is a most extensive race, including nearly all the nations enumerated in the first division, with the skin, although white, possessing more or less of a brown tint, with black hair and dark eyes.

2. Yellow or olive (*gilvus* seu *buxeus*, a middle tint between that of wheat and the boiled quince or dried lemon peel), which characterises the Mongolian tribes, usually called, together with the inhabitants of great part of Asia, Tartars (Tatars.)

3. Red or copper colour (*bronzè*, Fr. an obscure orange, or rusty iron colour, not unlike the bark of the cinnamon tree) almost confined to the Americans.

4. Tawny or brown (*badius*, *bafanè*, Fr. a middle tint between that of fresh mahogany and cloves or chestnuts), which belongs to the Malays, and the inhabitants of the South sea islands.

5. Black, in various shades from the sooty colour or tawny black, to that of pitch, or jet black. This is well known to prevail very extensively on the continent of Africa: it is found also in other very different and distant varieties of the human race, mingled with the national colour, as in the natives of Brazil, California, India, and some South sea islands, as New Holland and New Guinea. The New Caledonians constitute an insensible transition, with the chestnut coloured islanders of Tongataboo, from the tawny or brown Otaheitan to the black New Hollanders.

Intermediate Shades.—In describing these varieties, we fix

on the most strongly marked tints, between which there is every conceivable intermediate shade of colour. The opposite extremes run into each other by the nicest and most delicate gradations, in every other particular in which the human species differs. This forms no slight objection to the hypothesis of different species: for, on that supposition, we cannot define the number of species, nor can we point out the boundaries that divide them; whereas, in animals most resembling each other, the different species are preserved pure and unmixed. Neither does the colour, which we describe in general terms as belonging to any particular race, prevail so universally in all the individuals of that race as to constitute an invariable character, as we should expect, if it arose from such a uniform cause as an original specific difference: its varieties, on the contrary, point out the action of other circumstances. Thus, although the red colour is very prevalent on the American continent, travellers have observed fair tribes in several parts: as Bouguer, in Peru; Cook, at Nootka Sound; Humboldt, near the sources of the Orinoco; and Weld, near the United States. The natives of New Zealand vary from a deepish black to an olive or yellowish tinge. In the Friendly Islands, they are of a complexion deeper than the copper-brown; but several of both sexes are of the olive colour, and some of the women are much fairer.

Various Colours of Animals.—The domestic animals exhibit varieties entirely analogous to those which we have just enumerated; a fact so familiarly known, with respect to the sheep, pig, horse, and cow, that it cannot be necessary to support the assertion by any details. The leucæthiopic constitution, too, occurs in them as well as in the human subject: it has been observed (not to mention the well-known examples of the rabbit, ferret, mouse, and horse) in the monkey, squirrel, rat, hamster, guinea-pig, mole, opossum, martin, weasel, and roe. The crow, black-bird, canary bird, partridge, common fowl, and peacock, are sometimes the subjects of it; but it has never been seen in any cold-blooded animal. Blumenbach, l. c.

Colour and Denominations of the mixed Breeds.—When two varieties copulate together, the offspring resembles neither parent wholly, but partakes of the form and other peculiarities of both. This cannot with propriety be termed hybrid generation; as authors apply that expression to the produce of the copulation of different species, as of the horse and ass, the canary bird and gold-finch, &c. In this sense, hybrids are never produced in the human species. We read, indeed, various instances of this unnatural commerce, either where men, from depraved passions, solitary life, or mistaken notions of sanctity, have been connected with animals: see J. Warton, in a note on Theocr. Idyll. i. 88. p. 19. “*Audivi ex docto quodam amico, qui per Siciliam insulam iter faciens, ibidem cum vetera monumenta, tum populi mores accuratius investigaverat, inter confessionis articulos a Siculis caprariis apud montes vitam solitariam degentibus, etiamnum per sacerdotas proprios rite soleri exigi an rem cum hircis suis habuerint:*” and M. Baumgarten, *Peregrinatio in Ægyptum, Arabiam, &c.* p. 73. “*Ibi vidimus sanctum unum Saracenicum, inter arenarum cumulos ita ut ex utero matris prodiit, nudum sedentem. Audivimus sanctum illum, quem eo loco vidimus, publicitus apprime commendari; cum esse hominem sanctum, divinum, ac integritate præcipuum, eo quod nec feminarum usquam esset nec puerorum, sed tantummodo asellarum concubitor atque mularum:*” or with the view of deriving benefit when ill, as Pallas states; “*Perfas ischiade laborantes onagras inire,*” *Neuen Nordischen Beyträgen*, P. 2. p. 38: or, where women, from lust or religious motives, have solicited

the embraces of male animals, Steller of the Kamtschatkan Women, in *Beschreibung von Kamtschatka*, p. 289; and the Mendesian women with the sacred goat, *D'Hancarville Recherches sur l'Origine des Arts de la Grece*, tom. i. p. 320. The laws of various countries, too, have directed that the fruit of such intercourse should be burned, or otherwise destroyed. Yet there is no instance, related by witnesses worthy of credit, or with circumstances sufficient to authenticate it, of any offspring being produced. We only speak of such hybrids as result from the union of different varieties, as of the green and white canary birds; which unions have a most remarkable effect on the progeny, and are employed with wonderful advantage in improving the breeds of the domestic animals, particularly the horse and sheep.

Children, produced from the copulation of different races, exhibit in their colour the middle between the two tints of their parents. From a refinement of vanity, the inhabitants of the Spanish colonies in America have enriched their language with terms for the finest shades, which result from the degeneration of the primitive colour.

In the first generation, the offspring of Europeans and Negroes are called Mulattos. The word Creole (*Criollo*) has been frequently confounded with this, even by good writers; but that name (originally applied by the first Negroes, conveyed to America in the sixteenth century, to their children born in that country, and borrowed by the Spaniards from them to denote their own offspring in the New World; Garcilasso del Origen de los Incas) belongs properly to the children of European parents born in the East or West Indies. The offspring of Europeans and Indians are called Mestizos; of Europeans and Americans, Mestizos, also Mestindi, Metisi, and Mamelucki; of Negroes and Americans, Zambos or Sambos, also Mulattos, Lobos, Curibocas, and Kabuglos.

“The descendants of Negroes and Indian women bear at Mexico, Lima, and even at the Havannah, the strange name of Chino, Chinese. On the coast of Caraccas, and, as appears from the laws, even in New Spain, they are called Zambos. This last denomination is now principally limited to the descendants of a Negro and a female Mulatto, or a Negro and a Chinese female.” Humboldt's political Essay on New Spain, vol. i. p. 244.

All the above enumerated descriptions of persons have the middle countenance and colour, formed by the union of those of both parents; the latter is more or less brown or tawny, with hardly any visible redness of the cheek. The hair of the Mulattos is curled; in the other instances straight, and almost invariably black: the iris is dark. “A Mestizo,” says Humboldt, “is in colour almost a pure white; and his skin is of a particular transparency. The small beard, and small hands and feet, and a certain obliquity of the eyes, are more frequent indications of the mixture of Indian blood, than the nature of the hair.” *Ibid.*

In the second generation, two Mulattos produce Cafquos; Europeans and Mulattos, Tercerons, called by some authors Quarterons, Moriscos, and even Mestizos. The hair and countenance of these resemble the European: the skin has a very slight brown tint, and the cheeks are red. The scrotum is blackish in the male, and the labia pudendi rather purple in the female.

Negroes with Mulattos produce Griffos (*Zambos de Mulata, or Cabros*); an European and Indian Mestize, Calbissos. “If a Mestiza marry a white man, the second generation differs hardly in any thing from the European race.” (*Humboldt, ibid.*) From an European and American

rican Mestizo come Quarterons (Quatralvi or Castiffi); from an American and a Mestizo, Trelavos; from an American and Mulatto, Mestizos; from an European and Zambo, Mulattos; from an American and Zambo, Zambaigos. The offspring of the Zambos are styled in derision by the Spaniards Cholos; that of a Negro and Zamba is called Zambo prieto (black Zambo).

In the third generation, Europeans and Tercecerons produce Quaterons or Quarterons (Ochavons, Octavons, or Alvinos), which, according to the most acute observers, retain no traces of their African original; a Mulatto and Terceceron produce a Saltatra; an European and Castiffo, a Potiffo; an European and American Quarteron of the second generation, an Octavon; a Quarteron and American Mestizo of the first generation, a Coyota; a Griffon and a Zambo of the first generation, a Givero; a Zambaigo and Mulatto, a Cambujo.

Some carry the genealogy of these hybrid races into the fifth generation, and call the children of Europeans and

Quarterons, Quinterons (or Puchuelas); which name is also given to those born of Europeans and American Octavons; but it is not credible that any trace of mixed origin can remain in this case, according to the observation of the most respectable eye-witnesses concerning the third generation; that in colour and habit of body they cannot be distinguished from their European progenitors.

In countries with a mixed population, governed by whites, the families reputed to have the least mixture of black blood are naturally the most honoured. In America, the greater or less whiteness of the skin decides the rank which an individual occupies in society. When a common man disputes with one of his superiors, he is frequently heard to say, "Do you think me not so white as yourself?" It becomes, consequently, a very interesting business for the public vanity to estimate accurately the fractions of European blood which belong to the different casts. The proportions are represented below, according to the principles sanctioned by usage.

Parents.	Offspring.	Degree of Mixture.
White and Black,	Mulatto,	$\frac{1}{2}$ white $\frac{1}{2}$ black.
White and Mulatto,	Terceceron,	$\frac{2}{4}$ white $\frac{2}{4}$ black.
Black and Mulatto,	Griffo or Zambo,	$\frac{1}{3}$ black $\frac{2}{3}$ white.
White and Terceceron,	Quarteron,	$\frac{3}{4}$ white $\frac{1}{4}$ black.
Black and Terceceron,	Quarteron,	$\frac{3}{8}$ black $\frac{5}{8}$ white.
White and Quarteron,	Quinteron,	$\frac{4}{16}$ white $\frac{12}{16}$ black.
Black and Quarteron,	Quinteron,	$\frac{12}{16}$ black $\frac{4}{16}$ white.

The two latter are respectively reputed white and black; the former are white by law, and consequently free in our West India islands. They are not distinguishable from pure whites in complexion, features, or hair.

Thus, in obedience to that principle, by which the properties of the offspring depend on those of the parents, we have the power of changing one species into another by repeated intermixture. If the offspring of a white woman and a black be matched with a black man, and this process be repeated two or three times, the form of the original mother is entirely lost, and that of the father substituted; or, *vice versa*: and the same may be done with plants.

Exceptions to the Law concerning the Colour of the mixed Breeds.—Although the children generally partake of the character of both parents, they sometimes resemble one only; and in such a case, the influence of the other is often observed in the second or third generation. We see children like their grandfathers, and unlike the father and mother.

"Fit quoque, ut interdum similes existerent avorum
 Possint, et referant proavorum sæpe figuras.

* * * * *

Inde Venus varias producit forte figuras,
 Majorumque refert voltus, voceque, comasque."

Lucretius, lib. ii.

Thus, a white Negress (Albiness) married an Englishman, and brought forth three true Mulattos, but with light hair. (Blumenbach, *Beyträge*, p. 125.) The offspring of a black and white may be either black or white, instead of being mixed; and in some rare cases it has been spotted.

A black man married a white woman in York, who in due course of time had a child that was entirely black, and very much like the father both in colour and features, without the least participation of the features or colour of the mother. A black man married a white woman in London, who afterwards had a daughter as fair as any one born of white parents, and like the mother in features; but her right buttock and thigh were as black as the skin of the

father. A Negro woman had a white daughter by a man of her own race: white children had been frequently born in his family, and his own father was one of these; but his grandfather and grandmother were black. Parsons in *Phil. Transf.* vol. iv.

A Negress had twins by an Englishman: the one was perfectly black, with short, woolly, curled hair; the other was white, with long hair. White on the regular Gradation, p. 122.

Production of Varieties.—It is a general law, that animals produce their like; and thus species and races preserve uniformity of character. But this resemblance between children and their parents is not constant: the former, under certain circumstances, differ from the latter; and thus we have persons in each race, with characters approaching to those of the other races. In European countries, scattered instances of individuals, with skins nearly as dark as those of the Mongols or South sea islanders, are not unfrequent. Forster, in his voyage round the world, saw a man with fair skin and red hair in an island, where the inhabitants in general are nearly black. Among the Otahiteans, who are descended from the Malay race, light complexions and flaxen hair are not very uncommon; and red-haired individuals have been observed in most of the dark coloured nations, as the Wotiaks, Esquimaux, islanders of New Guinea and New Zealand, and the Negroes. (Blumenbach, p. 169.) Again, the origin of Albinos, particularly in the black nations, is a remarkable example of native variety of colour.

Instances analogous to these are of daily occurrence among animals, as in the production of black sheep, cats, horses, foxes, &c. White sheep produce black lambs; and grey rabbits may bring forth either white (leucæthiopic) or black ones. Two common peacocks produced fourteen young: two of them were white, and the rest resembled their parents. (Buffon, vol. xii. p. 286, note.) Leucæthiopic animals are constantly produced from those of the ordinary characters.

The native varieties, thus produced, are propagated by generation,

generation, and become established as permanent breeds; if individuals with these new characters constantly intermix. Thus, the leucæthiopic constitution has become fixed in the white rabbit and ferret; and thus, before our eyes, as great a deviation from the common stock has been formed, as any in the human race. Black rams are always rejected in breeding, because they would transfer this colour to their progeny. In many parts of England, all the cattle are of one colour: this arises from the long-established custom of slaughtering all the calves which have not the desired tint. (Prichard de Hom. Variet. p. 32.) We have no reason to doubt, that if the same plan were adopted with the human subject, that is, if persons marked by certain native peculiarities were united, their offspring again matched with similar individuals, and this constantly repeated, that any native variety might be fixed as a permanent breed. Human Albinos are so few, that this cannot be effected; and hence we have no race like the ferret or white rabbit. Travellers indeed report, that tribes of Albinos are found in Java, where they are called Kakkerlakken (Chacrelas); in Ceylon, (Bedas); and in the isthmus of Darien. (See Buffon, vol. iii. p. 328. 344. 419.) The statement concerning the latter is the most circumstantial, and possesses the strongest appearance of authenticity: but none of those, who speak of these white Indians, saw more than one or two of them; and we believe that subsequent reports have by no means corroborated the notion that whole nations of such people exist. Hence we are to regard leucæthiopia as having occurred only in scattered instances in the human subject, and as having been very rarely transmitted by generation, because the individuals are not numerous enough for them to breed together.

The disposition to change is exhausted in one generation, and the characters of the original stock return, unless the variety is kept up in the manner above mentioned; that is, when Albinos intermix with the common race, the offspring resembles the latter. A white Negroes brought forth to a Negro a perfectly black son. (Blumenbach, Beyträge, p. 125.) And the same circumstance is seen in vegetables: the variegated holly can only be preserved as a variety by grafting; when we attempt to propagate it by seed, it returns to the common green holly.

In considering this as an explanation of the varieties of colour, an objection will probably occur; that we do not, in point of fact, see Negroes or Americans produced among the white races, nor Europeans among the former. If it were necessary to our theory to prove that such varieties do occur, we should deem it untenable: but the Negro and the European are the two extremes of a very long gradation; between them are almost innumerable intermediate stages, which differ from each other no more than the individuals, occasionally produced in every race, differ from the generality of the race.

Spotted Individuals.—Examples occur of individuals spotted with different colours; but they are by no means so common as those of spotted animals. See, on this subject, the *variations in the formation of the skin*, in the article MONSTER.

Other Properties of the Skin.—The skin differs in some other properties besides its colour. Travellers have described it as remarkably soft and smooth, and as it were silky, in the Carib, Negro, Otaheitean, and Turk. It ferretes a matter of peculiar odour in some races. “The Peruvian Indians,” says Humboldt, “who, in the middle of the night, distinguish the different races by their quick sense of smell, have formed three words to express the

odour of the European, the Indian American, and the Negro: they call the first *pezuña*, the second *posco*, and the third *graió*.” Humboldt, p. 245.

The hair, as it grows and is nourished from the common integuments, is connected with them in many points by a close kind of sympathy. Hence the spotted Africans have white hairs growing out of a white patch on the head. The four last of the varieties mentioned in the description of the colours of men, have black hair; and in the first, or the white, every gradation from the fair to the dark, is accompanied by correspondent alterations in the hair. This is true, not only of nations, but also of individuals in the white races. A light complexion and thin skin are accompanied with red or fair hair; a dark one, and thick skin, with black hair, almost invariably, even in individuals of the same family; a difference, which, according to the philosophy of some writers, would be a sufficient ground for classing them in different species. The other properties of the hair vary, as well as its colour; and these changes may be brought under the four following varieties:

1. Brownish, deviating into red on one side and black on the other; this is copious, soft, and long, and slightly undulated. It obtains in most of the temperate climates of Europe, and formerly attracted particular notice in the ancient Germans. The thin and white skinned Albino has the softest and finest hair, of a white colour: in the Germanic race it is also very soft; and red hair is usually found in conjunction with a thin and soft skin. The Celtic and Slavonic races, which make up the chief population of Europe, and the eastern Asiatics and northern Africans have generally, with a rather thicker and darker skin, stronger, black, or darkish brown, and often more or less curling hair.

2. Black, strong, straight, and thin; occurring in the Mongolian and American races.

3. Black, softer, dense, copious and curled; observable in most of the South Sea islands.

4. Black, and crisp, so as generally to be called woolly; common to all the Ethiopians.

The analogy, on which the covering of the Africans has thus been called wool, is quite a loose one, and goes no further than a slight resemblance in appearance. The filament in wool is rough on its surface, in the hair it is smooth: the latter is of uniform thickness throughout, or rather slenderer towards the point, while the former is unequal in size, and rather larger towards its end. The wool is detached altogether, while the hairs fall off separately. In none of these characters does the hair of the African agree with wool.

The above division, although sufficient for general purposes, is not uniformly true. For the woolly hair is not confined entirely to the Ethiopians, nor is the black colour invariably found in all the three last varieties. Some tribes of Africans have long hair, (Bruce of the Gallas) and other red coloured people, as those of the Duke of York's island, have it strongly curled. The New Hollanders form so complete a medium between the woolly haired African, and the copious curling hair of the other South Sea islands, that we are completely puzzled how to class them. Individual instances of red hair occur in all the three last varieties.

The soft white hair of the Albino may be produced in any race of mankind; and is most widely different from the black hair of the dark varieties.

The animal kingdom furnishes us with numerous parallel instances of varieties in the colour and texture of the hair; as, for example, in the black sheep, black and white horses, &c. The sheep exhibit every kind of covering, from the

delicate fleeces of Thibet or Spain, to the coarse and rough hair which takes the place of wool in many warm countries.

The bristles of the pig are so soft in some kinds, as in Normandy, that they are not applicable to the manufacture of the ordinary instruments. The wild pig has a soft curling hair interposed between its bristles, which is entirely lost in the domesticated animal.

Sheep, rabbits and cats in Angora, a small district of Asia Minor, are remarkable for the length and softness, as well as snowy whiteness of their coverings.

The sheep of some of the Tatar tribes have hairs mixed with the wool: such a mixture is observed even in this country, where the breed is neglected; and it occurs in the Argali, the supposed wild origin of our flocks. In these cases, if the animals with the best fleeces are selected to breed from, and this rule be observed constantly, the wool would be gradually improved, and the hairs disappear; or *vice versa*, the sheep would become entirely hairy.

A child born in Yorkshire of European parents, had the woolly hair; and this is not the only example. Prichard de Generis Hum. Variet. p. 26.

It must appear very clearly, from these analogies, that the differences of the hair will not warrant us in establishing distinct species of men.

Together with the differences of the hair we may mention those of the beard. This growth is small in quantity, and thin in many tribes of the Mongolian, African and American races. "One of the most general characters of the ugly nations," says Meiners, "is either an entire want of beard, or a very thin one, developed at a later period than usual: on the contrary, a copious beard has always been the pride of the handsome races. Dark coloured nations, with strong beards, are not much more numerous than individuals of handsome people with a weak growth." Grundriss, p. 98.

Unfounded reports have been generally received of its entire absence in the Americans, and this circumstance has been represented as a characteristic peculiarity of the race. The concurring testimonies of all accurate modern travellers prove clearly that the Americans have naturally beards; that it is a very general custom with them, as it has been with several Mongolian and Malay tribes, carefully to eradicate this excrescence; but that various hordes in different parts of the continent preserve it as other men do. Gmelin found this practice in Asia. "It is not easy to find a Tungoose, nor any man of the neighbouring tribes, with a beard. For they extract the hairs as soon as they appear, and repeat this process until at last no more are formed." (Reise durch Sibirien, t. 2. p. 125.) The same circumstance is reported of the Sumatrans by Marfden; of the Mindanao islanders by Forrest; of the Pelew islanders by Wilson; the inhabitants of New Guinea by Carteret; and those of Navigators isles, by Bougainville. From a cloud of unanimous testimonies concerning the Americans, we extract the following statement of Cook respecting the inhabitants of Nootka Sound: "Some have no beards at all, and others only a thin one on the point of the chin. This does not arise from an original deficiency of hair in those parts, but from their plucking it out by the roots; for those, who do not destroy it, have not only considerable beards on every part of the chin, but also whiskers, or mustachios, running from the upper lip to the lower jaw obliquely downwards." (Last Voyage, v. 2. p. 240.) The testimony of Humboldt concerning the South Americans is to the same effect: "The Mexicans, particularly those of the Aztec and Otomite races, have more beard than I ever saw in any other Indians of South Ame-

rica. Almost all the Indians in the neighbourhood of the capital wear small mustachios."—"I can affirm that the Indians, who inhabit the torrid zone of South America, have generally some beard; and that this beard increases when they shave themselves."—"Mr. de Galeano, in the account of the last Spanish expedition to the Straits of Magellan, informs us that there are many old men among the Patagonians with beards, though they are short, and by no means bushy." (Political Essay on the Kingdom of New Spain, v. 1. p. 147.) The existence of a beard, and the habit of extirpating it, are mentioned of the Greenlanders, by Cranz, Geschichte von Grönland; by Charlevoix of the Eskimaux, Nouvelle France, iii. p. 179; by Oldendorp of the Caribs, Geschichte der Mission auf den Karaibischen Inseln; p. 22; By Wafer of the Americans at Panama, Isthmus of America, p. 106; by Bougainville of the Patagonians, Voyage autour du Monde; and by Parkinson, of the inhabitants of Terra del Fuego, voyage v. 1. Commerçon speaks of the whiskers of the Patagonians, Journal Encyclop. 1772.

Colour of the Iris.—We have just explained how the hair is connected with the skin: that a similar connexion in point of colour exists between the latter organ and the eyes, was noticed by Aristotle, who observed that white persons have blue eyes, and black ones black. Thus, in Germany, Blumenbach says that newly-born children have generally blue eyes and light hair, and that both grow gradually dark together in individuals who become dark. Again, the pigmentum of the eye loses much of its colour in proportion as the hair grows grey in the old subject. With their peculiar hair and skin, the Albinos have an entire deficiency of the pigment, and consequently a pale red iris. Those animals only which vary in the colour of the skin and hair, have differently coloured irides; and this is true, not only of men and horses, according to the opinion of the ancients, but of other animals, particularly in the domesticated state. Moreover, the iris is often variegated in animals which have a spotted skin. This has been noticed in dogs (Comment. Instit. Bonon. t. iii. p. 281.). Blumenbach has observed something of it in horses and sheep, but more particularly in rabbits: the grey, or those which have the native colour of their wild state, have dark irides; the spotted have them marked with different colours; and the white, like other Leucæthiopic animals, have them of a pale rose colour.

The three principal colours of the human eye were well laid down by Aristotle; *viz.* 1, blue, passing, in its lighter tints, to what we call grey; 2, an obscure orange, which he calls the colour of the eye in the goat (Gall. Yeux de Chevre:;) it is a kind of middle tint, between blue and orange, and sometimes remarkably green in men with red hair and freckled skin; and 3, blackish brown.

These may all occur in different individuals of the same race; and again, they are sometimes confined to the different tribes of the same country, within the boundaries of a few degrees. Thus Linnæus describes in Sweden the Gothlander with light hair and greyish-blue eyes; the Fin with yellow hair and brown iris; and the Laplander with black hair and iris. Blue eyes, as well as yellow hair (*rutilæ lat.* denoting the resemblance to gold, whence *auricomi Batavi*, Silius: *ξανθοί*, Gr.) were formerly set down among the characters of the Germans (*cærulei oculi, rutilæ comæ*, Tacitus); and the same combination is met with in scattered instances, in the most remote nations. The iris of the negro is the most intensely black, so that very close inspection is necessary, in living individuals, to distinguish it from the pupil.

Differences of Form.—The existence of great variations in the

the conformation and proportions of the body in all animals, and particularly of the features of the human countenance, subject, however, to certain fixed rules as to the general model, accords entirely with what we observe throughout all nature.

“Præterea genus humanum, mutæque natantes
Squammigerum pecudes, et læta armenta, feræque,
Et variæ volucres; lætantia quæ loca aquarum
Concelebrant, circum ripas, fontesque, lacusque;
Et quæ pervolgant nemora avia pervolitantés;
Horum unum quodvis generatim fumere perge:
Invenies tamen inter se distare figuris.
Nec ratione alia proles cognoscere matrem,
Nec mater possit prolem; quod posse videmus,
Nec minus atque homines inter se nota cluere.”

National Features.—Although it is a common and very just observation, that two individuals are hardly to be met with possessing exactly the same features, yet there is generally a certain cast of countenance common to the particular races of men, and often to the inhabitants of particular countries. The five following varieties are established by Blumenbach, after a careful comparison of numerous drawings, and of the various races themselves, in situations, where commerce attracts them from all parts of the globe, as at London and Amsterdam.

1. An oval and straight face, with the different parts moderately distinct from each other: forehead rather flattened, nose narrow, and slightly aquiline, or at least with the dorsum somewhat convex; no prominence of the cheek-bones; small mouth, with lips slightly turned out, particularly the lower one; a full and rounded chin.

This is the kind of countenance which accords most with our ideas of beauty: it may be considered as a middle, departing into two extremes, exactly opposed to each other; of which one consists in a lateral expansion of the face, and the other in its being extended downwards. Each of these includes two varieties, which are most readily distinguished by a profile view; one, in which the nose and other parts run together, and the other, in which they are more prominent and separate.

2. Broad and flattened face, with the parts slightly distinguished, and as it were running together: the space between the eyes flat and very broad; flat nose, rounded projecting cheeks; narrow and linear aperture of the eye-lids extending towards the temples (*Yeux bridés*, Fr.) chin slightly prominent.

This is the face of the Mongolian tribes; commonly called in English the Tartar face, from the confusion of the Tartars (*Tatars*) with the Monguls.

3. Face broad, but not flat and depressed, with prominent cheek-bones, and the parts, when viewed in profile, as it were, more deeply and distinctly carved out. Short forehead; eyes deeply seated; nose flattish, but prominent. Such is the countenance of most of the Americans.

4. Narrow face, projecting towards its lower part; arched forehead; eyes prominent (*a fleur de tête*); a thick nose, confused on either side with the projecting cheeks (*nez épâté*); the lips, particularly the upper one, very thick; the jaws prominent; and the chin retracted. This is the countenance of the Negro—the Guinea face.

5. The face not so narrow as in the preceding, rather projecting downwards, with the different parts in a side-view, rising more freely and distinctly. The nose rather full and broad, and thicker towards its apex (*bottle-nosed*). The mouth large. This is the face of the Malays, particularly of the South Sea islanders. Excellent representations of

celebrated individuals of these five varieties may be seen in Blumenbach's *Abbildungen Naturhistorischer Gegenstände*, part i.; also, in his *Beyträge zur Naturgeschichte*.

Intermediate Gradations and Varieties in the different Races.—In this respect, as in colour, the different characters run into each other by the most gentle gradations; so that, although any two extremes, when contrasted, appear strikingly different, they are connected by numerous intermediate and very slightly differing shades; and no formation is exhibited so constantly in all the individuals of one race, as not to admit of numerous exceptions.

In the Africans.—We see, indeed, an astonishing difference, when we place an ugly Negro (for there are such as well as ugly Europeans), against a specimen of the Grecian ideal model; but, when we trace the intermediate gradations, this striking diversity vanishes. “Of the Negroes of both sexes,” says Blumenbach, “whom I have attentively examined, in very considerable number, as well as in the portraits and profiles of others, and in the numerous Negro crania, which I possess, or have seen, there are not two completely resembling each other in their formation: they pass, by insensible gradations, into the forms of the other races, and approach to the other varieties even in their most pleasing modifications. A Creole, whom I saw at Yverdun, born of parents from Congo, and brought from St. Domingo by the chevalier Treytorens, had a countenance, of which no part, not even the nose, and rather strongly marked lips, were very striking, much less displeasing: the same features, with an European complexion, would certainly have been generally agreeable.” (*Beyträge zur Naturgeschichte*, p. 89.) The testimony of Le Maire, in his journey to Senegal and Gambia, is to the same effect; that there are Negroesses, except in colour, as handsome as European women. Vaillant says of the Caffre women, that, setting aside the prejudice which operates against their colour, many might be accounted handsome, even in an European country. The accurate Adanson confirms this statement, in his description of the Senegambians. “Les femmes sont a peu près de la taille des hommes, également bien faites. Leur form est d’une finesse et d’une douceur extrême. Elles ont les yeux noirs, bien fendus, la bouche et les levres petites, et les traits du visage, bien proportionnés. Il s’en trouve plusieurs d’une beauté parfaite. Elles ont beaucoup de vivacité, et sur tout un air aisé de liberté qui fait plaisir.” (*Hist. Nat. du Senegal*, p. 22.) The Jaloffs, according to Mungo Park, have not the protuberant lip, nor flat nose of the African countenance. We have also the testimony of another traveller, concerning this tribe, to the same effect: the Jaloffs, according to Moore, have handsome features, and neither broad noses nor thick lips. (Zimmermann *Geographische Geschichte*, &c. vol. i. p. 99.) Pigafetta states, that the Congo Negroes have not the thick lips of the Nubians, and that, except in colour, they are very like the Portuguese. (*Relazione del Reame di Congo*, Roma, p. 12.) Dampier, in his account of Natal, describes the natives as having curled hair, but a long face, well-proportioned nose, and agreeable countenance. The six Negro crania engraved in the two first decades of Blumenbach, exhibit very clearly this diversity of character in the African race; and prove, most unequivocally, that the variety among individuals is certainly not less, but greater than the difference between some of them and many Europeans. See *Decas Craniorum*, p. 22, and *Decas Altera*, p. 13.

In the Americans.—The same observations hold good of the American race. The most accurate observers treat with contempt the hyperbolic assertion of some, that all the inhabitants of the New World have one and the same countenance, so that he who has seen one may say that he has seen

all. "Rido fra me stesso," says Molina, "quando leggo in certi scrittori moderni riputati diligenti osservatori, che tutti gli Americani hanno un medesimo aspetto, e che quando se ne abbia veduto uno, si posse dire di avergli veduti tutti. Codesti autori si lasciarono troppo sedurre da certe vaghe apparenze di somiglianza precedenti per lo piu dal colorito, le quali svaniscono tosto che si confrontano gl' individui di una nazione con quelli dell' altra. Un Chilense non si differenzia meno nell' aspetto da un Peruviano, che un Italiano da un Tedesco. Io ho veduto pur dei Paraguaii, de' Cujani, e dei Magellanici, i quali tutti hanno dei lineamenti peculiari, che li distinguono notabilmente gli uni dagli altri." (Storia Naturale del Chili, p. 336. We have further unexceptionable testimony to prove that the same variety of countenance is found in the Americans as in other races; although generally the countenance follows the model above described. In South America only we have the Caaguas with flat noses, observed by Nic. del Techo; the neighbouring Abipons, of whom many individuals have aquiline noses, by Martin Dobrizhoffer; the Peruvians with narrow and aquiline nose by Ulloa; the Chilense with rather a broad nose by Molina; and the islanders of Terra del Fuogo with a very depressed one by G. Forster. The truth of this representation is most fully attested by Humboldt, whose accuracy and extensive opportunities entitle his observations to the most implicit deference. "In the faithful portrait, which an excellent observer, Mr. Volney, has drawn of the Canada Indians, we undoubtedly recognise the tribes scattered in the meadows of the Rio Apure and the Carony. The same stile of feature exists, no doubt, in both Americas; but those Europeans who have sailed on the great rivers Orinoco and Amazons, and have had occasion to see a great number of tribes assembled under the monastical hierarchy in the missions, must have observed that the American race contains nations, whose features differ as essentially from one another, as the numerous varieties of the race of Caucasus, the Circassians, Moors, and Persians, differ from one another. The tall form of the Patagonians is again found by us, as it were, among the Caribs, who dwell in the plains from the delta of the Orinoco, to the sources of the Rio Blanco. What a difference between the figure, physiognomy and physical constitution of these Caribs, who ought to be accounted one of the most robust nations on the face of the earth, and are not to be confounded with the degenerate Zambos, formerly called Caribs of the island St. Vincent, and the squat bodies of the Chayma Indians of the province of Cumana! What a difference of form between the Indians of Tlascala and the Lipans and the Chichimeos of the northern part of Mexico." Political Essay on the Kingdom of New Spain, v. i. p. 142.

In the South Sea Islanders.—An analogous variety has been noticed in the features of the Friendly islanders: "their features are very various; inasmuch, that it is scarcely possible to fix on any general likeness by which to characterize them, unless it be a fulness at the point of the nose, which is very common. But, on the other hand, we met with hundreds of truly European faces, and many genuine Roman noses amongst them." Cook's Last Voyage, v. i. p. 385.

In Europeans.—Again, particular individuals in Europe often have the countenance exactly resembling the Negro, or Mongol face.

Differences in the Skull.—The form of the cranium in the different varieties of man has been described in the article CRANIUM; in which the causes of the diversities of its figure are also considered. We have one or two additional remarks to make, particularly concerning the Negro. "The

bony apparatus," says Soemmerring, "concerned in mastication, as well as the part of the face containing the organs of sense, are, whether considered generally or particularly, stronger, thicker, and more advantageously disposed for this strength in the Negro, than in the race where more extensive use of experience and reason, and greater cultivation supply the place of what is deficient in animal strength. Should we take the bones of the face in the Negro, as a basis, and add to them a cranium, according to the proportions observed in European heads, the space allotted for the reception of the organ of thinking would exceed the size that it has in us. Von der körperl. Verschiedenheit, § 12. The ridge that bounds the origin of the temporal muscle is more prominent, and rises much higher on the side of the head in the Negro, than in the European; consequently, the muscle is considerably larger, and the bony arch surrounding it (the zygoma), is larger, stronger, and more capacious. (Ibid. § 16 and 17.) Both openings of the nose are more ample, and the cavity itself considerably more capacious than in the European. The thin convoluted plates of the ethmoid bone are larger, and consequently increase the extent of the pituitary membrane: the cribriform plate is remarkably large. These circumstances of anatomical structure are not, however, peculiar to the Negro: Soemmerring finds the nasal cavity in the cranium of a North American savage still more ample than in most Negroes. (Ibid. § 21 and 22.) The instances related of the fineness of smell in these people, such as their being able to distinguish Europeans from Negroes and Americans, &c. correspond to what we observe in their organs.

"The nerves," says this anatomist, "connected with the basis of the brain, appear to me, in comparison with an European brain of the same size, to be, in proportion, rather larger; at least the olfactory, the fifth, and the facial nerves, are remarkably large, as we might have expected, from the greater size of the nose and face." § 56.

The relation between the cranium and face is best seen in a vertical section carried from before backwards: the area of the face, independently of the lower jaw, is about one-fourth of the cranium in the European; in the Negro, the cranium remaining the same, the face increases by about one-fifth. The proportion still increases in the orang-outang: in the papajous, the mandrills, and most of the carnivora, the face and cranium are about equal.

The ossa nasi of the Negro, instead of forming the bridge-like convexity which we see in the European, are nearly flat, and run together into an acute angle above, which makes them very much resemble the single triangular nasal bone of the ape. But in one cranium they exactly resemble the European. Ibid. § 19.

The varieties in the form of the teeth are also considered in the article CRANIUM.

Supposed Causes of Difference of Features: Climate.—That the national differences of features owe their origin to climate, has been the opinion of many philosophers; and some have even attempted to shew how the effect is produced. "En effet," says Volney, "j'observe que la figure des Negres représente précisément cet état de contraction que prend notre visage, lorsqu'il est frappé par la lumière et une forte réverbération de chaleur. Alors le sourcil se ferme; la pomme des joues s'élève; la paupière se ferme; la bouche fait la moue. Cette contraction, qui a lieu perpétuellement dans le pays nud et chaud des Negres, n'a-t-elle pas dû devenir le caractère propre de leur figure?" Volney, Voy. en Syrie et en Egypte, t. i. p. 74. It is unfortunate for these speculations that the most opposite kinds of features occur under similar climates in different parts of the world; and that there are races with flattened countenances, as well

as with prominent ones in hot countries. These causes, too, could only affect the soft parts: a negro might "faire la moue" to eternity, without altering the whole bony compages of his head. Indeed, the whole account is so fanciful, that it hardly deserves serious attention. If there were any foundation for the supposition, we might expect Mr. Volney's countrymen, from their well-known habit of shrugging the shoulders, to have become long ago the highest shouldered race in the world.

Artificial Pressure.—The custom of carrying the children on the back has been referred to by others, in order to explain the flat nose of the Negro: in the violent motions required for their hard labour, as in beating or pounding the millet, &c. the face of the young one is said to be constantly beating against the back of the mother. The testimonies concerning the employment of pressure, with a view to flatten the nose, are so numerous and respectable, that we cannot refuse to believe that it is attempted. (See Blumenbach, *de Varietate*, p. 193.) But two reasons prevent us from ascribing any efficacy to these practices in producing the national varieties of the cranium. The diversities extend so generally through the whole bony fabric of the head, and are observable in so many parts, where external pressure could have no influence, not to mention that they consist, in many instances, of formations just the reverse of what pressure would effect, that we must ascribe them to native variety. This determination is confirmed by the discovery, that all the peculiarities of the Negro cranium exist in the fœtus. The researches of Blumenbach, Camper, Soemmerring, Ludwig, and Loder, have proved this fact concerning Negro fœtuses of various ages, in whom they find the same prominence of the jaws, flat nose, &c. as in the adult. (Soemmerring *von der körperl. Verschiedenheit*, § 4. Ludwig *Grundriß der Naturgeschichte der Menschen Species*, p. 121.) The children of Negro parents in Europe, America, and other situations, where there are opportunities of knowing that no means are used to flatten the nose, resemble, in all respects, those born in Africa. These arguments receive a further confirmation from three of the crania engraved by Blumenbach, of a Jewish girl, five years old, a Mongolian child, a year and a half, and a newly born Negro, in which the characters of the Caucasian, Mongolian, and Ethiopian varieties are as strongly represented as in the heads of adults. *Decas tertia*, tab. 28—30. p. 14.

In the form and proportions of other parts, there are not fewer differences than in the composition of the features.

Differences in the Form and Proportions of other Parts.—*Connexion of the Head and Trunk.*—In consequence of the foramen magnum being placed further back in the head in the Negro than in the European (see CRANIUM), and of the head of the former being consequently placed further forwards on the vertebral column, the occiput projects less behind the spine. Hence, a line drawn from the occiput along the nape of the neck, is nearly straight in the Negro, but it dips in considerably under the head in the European; as if a part of the cranium had been sliced off in the former. The same circumstance may be observed in a much more striking degree in the Simia.

Body and Limbs.—The body is large, square, and robust; the extremities thick, short, and nervous; and the shoulders high in the Monguls. They are well described in a letter inserted in the *Historia Major* of Matthew Paris, London, 1686, p. 530, under the name of Tartars (Tatars). "Habent autem Tartari pectora dura et robusta, facies macras et pallidas, scapulas rigidas et erectas, nasos distortos et

breves, menta proeminens et acuta, superiorem mandibulam humilem et profundam, dentes longos et raros, palpebras a crinibus usque ad nasum pretensoas, oculos inconstantes et nigros, aspectus obliquos et torvos, extremitates ossifas et nervofas, crura quoque grossa, sed tibiae breviores, statura tamen nobis æquales; quod enim in tibiis deficit, in superioribus corpore compensatur."

In the negro the body is more slender, particularly about the loins and pelvis. The dimensions of the latter cavity are actually smaller than in the European: in the skeleton of a negro, twenty years old,

	Inches.	Lines.
The great diameter of the pelvis is	3	11½
The small	3	7½
In a negro boy of 14, the great diameter is	3	2
<small>small</small>	2	9
In an European of 16, the great	4	3
<small>small</small>	3	9
In an old European, inferior in stature to		
the negro of 20 years, the great	4	6
the small	3	11

Camper found that the great diameter (from one os innominatum to the other) was to the smaller (from the sacrum to the symphysis pubis)

In the negro as	-	39	to	27½
In the European as	-	41		27

yet the stature of the negro exceeded considerably that of the European. In another European the proportions were as 44 to 28. (See Soemmerring *über die körperliche Verschiedenheit*, p. 33.) Not only is the cavity smaller, but the bones composing it are slenderer; and the circumference has been noticed by travellers and others.

The same slenderness of the trunk may be observed in some of the Indians: it is at least apparent in the Lascars, who come to this country with the East India ships. Their legs are long.

Proportionate Length of the Arm and Fore-arm.—The limbs are smaller in the negro, and some differences are observable in particular parts. "I measured," says Mr. White, "the arms of about fifty negroes, men, women, and children, born in very different climates, and found the lower arm longer than in Europeans, in proportion to the upper arm, and to the height of the body. The first negro on the list is one in the Lunatic hospital at Liverpool; his fore-arm measures 12¾ inches, and his stature is only 5 feet 10½ inches. I have measured a great number of white people, from that size up to 6 feet 4½ inches, and among them one who was said to have the longest arms of any man in England, but none had a fore-arm equal to that of the black lunatic.

"I have measured the arms of a great number of European skeletons, and have found that the os humeri, or upper arm, exceeds in length the ulna, which is the longer bone of the fore-arm by two or three inches; in none by less than two, and in one by not less than 3½ inches. In my negro skeleton, the os humeri is only one inch and one-eighth longer than the ulna. In Dr. Tyson's Pigmy (*Simia fatyrus*), the os humeri and ulna were of the same length; and in my skeleton of a common monkey, the ulna is ¾ of an inch longer than the os humeri." White, on the *Regular Gradation*, p. 52, et seq.

As the comparison just mentioned leads to some interesting

ing results, we subjoin a tabular view of the chief particulars.

	Stature.		Length of	Length of
	Feet.	Inch.	os humeri.	ulna.
A female European skeleton	5	8½	12½	10
A male	5	8	13	9¾

—	5	—	12½	8¾
A Lascar	5	4	12¾	10½
Venus de Medicis	5	—	13½	9½
Tyfon's chimpanzee	2	2	5½	5½
Monkey	2	2	4¾	5

Legs of the Negro, and other Races.—The ancients noticed, what they regarded as defects in the form of the lower limbs in the Egyptians, Ethiopians, and Negro slaves. Soemmering observes, that the bones of the leg are directed outwards from the knee, so that the knees appear farther apart, and the feet rather bent outwards: he found the same circumstance in numerous living negroes. The femur and tibia are stated, both by him and White (who has given a comparative view of the bones of the negro and European leg and foot, pl. 1.), to be more convex in front than in the European. The calves of the leg are very high, so as to encroach upon the hams. The feet and hands, but particularly the former, are flat; the os calcis, instead of forming an arch, is continued in nearly a straight line with the other bones of the foot, which is remarkably broad. They both terminate in beautiful, but remarkably long fingers and toes, which in that respect approach to those of the monkey; and they all possessed, what is not common among Europeans, sesamoid bones. (Von der körperlichen Verchiedenheit, p. 39.) Unfeemly thickness of the legs is not uncommon among the negroes; and the feet are marked with numerous chinks and fissures, which, as they occur principally in the soles, must probably be referred to the operation of the burning sands on the epidermis. In the sole of a perfectly healthy negro leg, Blumenbach found this covering “mirum in modum crassa, rimosa, et in multifidas lamellas dehiscens.” De Gen. Hum. Var. Nat. p. 246, note b.

It has been observed, that the Indians of the peninsula and the New Hollanders have long and slender limbs; that the Hottentots have meagre bodies and small limbs, &c. The crooked legs so common among the Calmucks, have been assigned to their mode of treating the children, and the practice of riding, to which they are accustomed from their tenderest years. Pallas über die Mongolischen Völkerschaften, p. 98, tom. i.

The lower limbs are very ill formed in the inhabitants of Terra del Fuego, according to Forster: he says that they bear no proportion to the body; that the thighs are meagre

and thin, the legs bowed, the knees prominent, the toes turned inwards. Obs. on a Journey round the World.

Ears.—It is well known that the ears stand off farther from the head, and are moveable in savages, and that the appendix is enlarged and monstrously elongated by various artificial means in many tribes, particularly in the East Indies and the Pacific. These practices have given rise to the fables of some older writers concerning the enormous ears of certain people.

Mammæ.—Many travellers have spoken of the prolix and pendulous mammæ of the females of certain barbarous tribes, particularly in Africa, and in the South sea islands. We cannot help suspecting that many of these narratives are exaggerated; as, for example, in Hakluyt's Collection, vol. ii. p. 26, where it is said, that “divers of the women have such exceeding long breasts, that some of them will lay the same upon the ground, and lie down by them;” in Bruce's Travels, where he says, that they hang down to the knees in some of the Shangallas; or in Mentzelius, Beschreibung des Vorgebürges der guten Hoffnung, tom. ii. p. 564, who says, that purses are made in great numbers from the breasts of the Hottentot females, and sold at the Cape of Good Hope. It is also certain that this conformation is not universal in the tribes alluded to, and that many negroes, who may be seen in the great European emporia, as well as numerous females in the isles of the Great Pacific (Forster's Observations, &c.), have very beautifully shaped breasts, and that it exists also in several European countries. “I saw,” says Lithgow, “in Ireland's North parts women travayling the way, or toying at home, carry their infants about their neckes, and laying the dugges over their shoulders, would give sucke to the babes behinde ther backes, without taking them in their armes: such kind of breasts, me thinketh, were very fit to be made money-bags for East or West Indian merchants, being more than halfe a yard long, and as well wrought, as any tanner, in the like charge, could ever mollifie such leather.” (Rare Adventures and Painfull Pereginations, p. 433.) An unusually large size of these parts has been observed in the Morlachian women, by Fortis, (Viaggio in Dalmazia, vol. i. p. 81;) and the Greenland women are said to suckle their children at their back.

Long continued suckling, and the habit of suckling the children on the back of the mother, seem to be the principal causes of this state of the mammæ. In some instances artificial means of elongation have been employed from peculiar notions of beauty.

A large and swollen state of the breast, is mentioned by Juvenal of the Egyptians, as a well-known fact. “In Meroe crasso majorem infante papillam.” The Portuguese women, of modern days, are said to be remarkable in the same way; while the breasts are small in the Spaniards, as in the last century at least they took pains to compress them in order to prevent too great a luxuriance.

To the disgrace of London, even in this truly pious age of societies for suppressing vice and distributing bibles, a philosophic foreigner has found in her streets a proof of the effects of too early venereal excitement in enlarging the breast; and has commemorated the fact in a classical work, which must convey the scandal over the whole learned world. “Contraria cura ambitum mammarum augeri posse nullum dubium est; quantum vero præterea Venus quoque præmatura eo conferre possit memorabili sane exemplo impuberes et nondum adultæ puellæ mercenariæ docent quæ Londinum, præsertim ex vicinis maxime suburbiis, conflunt, et quantum

quæstum corpore facientes ingenti numero plateas noctu pervagantur." De Gen. Hum. Variet. p. 239.

Organs of Generation.—Negroes are particularly famous for their organs of generation: and specimens preserved in anatomical cabinets seem to justify their celebrity for the size of these parts; but it is doubtful whether this be a general character. The frænum preputii does not exist in many of them. White, p. 62.

In the Hottentot women, and in some others, the nymphæ are said to form growths of considerable size (in dactyli-formes appendiculas abire); but the former are more celebrated for what has been described as a natural covering of skin, hanging from the abdomen, and hiding the parts of generation. This, with other arguments of equal force, is brought forward by Voltaire, to prove that the Hottentots are not of the same species with Europeans. (Lettres d'Amabed.) Blumenbach, who received from sir Joseph Banks, several views of these parts, drawn from the life, informs us that the peculiarity is an artificial elongation of the labia pudendi; in one representation they are 6½ inches long. Le Vaillant's testimony is to the same effect. Voyage dans l'Inter. de l'Afrique, p. 371. See GENERATION.

Hands and Feet.—Smallness of the hands and feet has been mentioned as a character of some races, as the Indians, Chinese, Kamtschatkans, Eskimaux, Peruvians, New Hollanders, and Hottentots. "It has been observed," says Hodges, "of the arms of the Hindoos frequently brought to England, that the gripe of the fabre is too small for most European hands." Travels in India, p. 3.

What art can produce in this way, is shown by the feet of the Chinese women.

Transmission of native Characters to the Children.—Peculiarities of form, like those of colour, are transmitted to the offspring; and this principle prevails so generally, that even those minute, and to our senses entirely imperceptible differences of organization or vital properties, which render men disposed to particular diseases, are conveyed from father to son for age after age. Hence we see a general resemblance in persons of the same blood, and may frequently observe a peculiar feature running through a whole family. The thick lip introduced into the imperial house of Austria by the marriage of Maximilian to Mary of Burgundy, is visible in their descendants to this day. In small and secluded communities, where marriages take place within what we may regard only as a more extensive family, hereditary varieties are blended, and produce one form, which prevails through the whole circle. The operation of this principle may be clearly perceived in several small districts: it will act with more efficacy, and consequently be more discernible, in larger collections of men, where differences of manners, religion, and language, and mutual animosities, forbid all intermarriages with surrounding people. In the course of time the individual peculiarities are lost, and a natural characteristic countenance or form is established, which, if the restrictions of intercourse are rigidly adhered to, is constantly more and more strengthened. The ancient Germans, according to the description of Tacitus, were such a people, and his short, but expressive sketch of their character, most aptly confirms the preceding view: "Ipse eorum opinionibus accedo, qui Germaniæ populos nullis aliis aliarum nationum connubiis infectos, propriam & sinceram, et tantum sui similem gentem exstitisse arbitrantur. Unde habitus quoque corporum, quanquam in tanto hominum numero, idem omnibus; truces & cærulei oculi, rutilæ comæ, magna corpora." De Morib. Germ. 4. The gypsies afford another example of a people spread over all Europe for the last four centuries, and nearly confined in marriages to their

own race, by their peculiar way of life. In Transylvania, where there is a great number of them, and the race remains perfectly pure, their features can consequently be more accurately observed: in every country and climate, however, which they have inhabited, they preserve their distinctive character so perfectly that they are recognized at a glance, and cannot be confounded with the natives: see the description and figure of the cranium of a Transylvanian Gipsy, in Blumenbach, Decas Altera, p. 3. But, above all, the Jews exhibit the most striking instance of a peculiar national countenance, so strongly marked in almost every individual, that persons the least used to physiognomical observations detect it instantly, yet not easily understood or described. Religion has, in this case, most successfully exerted its power in preventing communion with other races; and this exclusion of intercourse with all others has preserved the Jewish countenance so completely in every soil and climate of the globe, that a miracle has been thought necessary to account for the appearance.

In what other way can we explain the difference between the English and Scotch? Would it be more reasonable to suppose that they descended from different stocks; or to ascribe the high cheek bones of the latter to soil or climate?

Alteration of Form by Breeding.—As, on the one hand, a particular form may be perpetuated by confining the intercourse of the sexes to individuals in whom it exists; so, again, it may be changed by introducing into the breed those remarkable for any other quality. Connections in marriage will generally be formed on the idea of human beauty in any country; an influence this, which will gradually approximate the countenance towards one common standard: If men, in the affair of marriage, were as much under management as some other animals, an absolute ruler might accomplish, in his dominions, almost any idea of the human form. The great and noble have generally had it more in their power than others to select the beauty of nations in marriage; and thus, while, without system or design, they gratified merely their own taste, they have generally distinguished their order, as much by elegant proportions of person, and beautiful features, as by its prerogatives in society. "The same superiority," says Cook, "which is observable in the Erees or nobles in all the other islands; is found also here (Owhyhee.) Those, whom we saw, were, without exception, perfectly well formed; whereas, the lower sort, besides their general inferiority, are subject to all the variety of make and figure that is seen in the populace of other countries." (Third Voyage, book iii. chap. 6.) In no instance, perhaps, has the personal beauty of a people been more improved, by introducing handsome individuals to breed from, than in the Persians, of whom the nobility have, by this means, completely succeeded in washing out the stain of their Mongolian origin. "That the blood of the Persians," says Chardin, "is naturally gross, appears from the Guebres, who are a remnant of the ancient Persians, and are an ugly, ill-made, rough-skinned people. This is also apparent from the inhabitants of the provinces in the neighbourhood of India, who are nearly as clumsy and deformed as the Guebres, because they never formed alliances with any other tribes. But, in the other parts of the kingdom, the Persian blood is now highly refined by frequent intermixtures with the Georgians and Circassians, two nations which surpass all the world in personal beauty. There is hardly a man of rank in Persia, who is not born of a Georgian or Circassian mother; and even the king himself is commonly sprung, on the female side, from one or other of these countries: as it is long
since

since this mixture commenced, the Persian women have become very handsome and beautiful, though they do not rival the ladies of Georgia. The men are generally tall and erect: their complexion is ruddy and vigorous, and they have a graceful air, and an engaging deportment. The mildness of the climate, joined to their temperance in living, has a great influence in improving their personal beauty. This quality they inherit not from their fathers; for, without the mixture mentioned above, the men of rank in Persia, who are descendants of the Tartars, would be extremely ugly and deformed." *Voyage en Perse, &c.* tom. ii. p. 34.

The transmission of natural peculiarities, by generation, is remarkably illustrated by some instances of unusual formation: such is the family of the porcupine men, and of the six-fingered and six-toed persons, both produced from individuals of the common form. (See, for the former, the article MONSTER, and for the latter, GENERATION.) There is no reason to doubt, that if the individuals, with these peculiarities, had been carefully matched together, that a permanent variety might have been established.

Let us suppose that the porcupine family had been exiled from human society, and obliged to take up their abode in some solitary spot, or desert island; by matching with each other a race would have been produced, more widely removed from us in external appearance than the negro. If they had been discovered at some remote period, our philosophers would have explained to us how the soil, air, or climate, had produced so strange an organization; or would have demonstrated that they must have sprung from an originally different race: for who would acknowledge such brittle beings for brothers?

We learn that the giants, collected with such pains by Frederic William I. for his regiment of guards, produced, in a town of Germany, where they were quartered, a very tall race of men: in the language of Dr. Johnson, they "propagated procerity."

Corresponding Varieties in Animals.—There is none of the varieties above enumerated, which does not exist in a still greater degree in animals confessedly of the same species. What differences in the figure and proportion of parts in the various breeds of horses; in the Arabian, the Barb, and the German! How striking the contrast between the long-legged cattle of the Cape of Good Hope, and the short-legged of England! The same difference is observed in swine. The cattle have no horns in some breeds of England and Ireland; in Sicily, on the contrary, they have very large ones. A breed of sheep, with an extraordinary number of horns, as three, four, or five, occurs in some northern countries, and is accounted a mere variety (*ovis polycerata*); the Cretan breed of the same animal, has long, large, and twisted horns. We may also point out the foliangular swine, with undivided hoof, as well as others, with three divisions of that part; the five-toed fowl (*gallus pentadactylus*); the broad-tailed sheep of Tatar, Thibet, &c. in which the tail grows so large that it is placed on a board, supported by wheels, for the convenience of the animal; and the rumpless fowl (*gallus ecaudatus*), of America, and particularly Virginia, which has undoubtedly descended from the English breed.

The common fowl, in different situations, runs into almost every conceivable variety. "*E volucris altilibus varietatum numero et insigni discrepantia certe eminent gallinae. Habentur magnæ, minutæ, proceræ, pumilionæ, cristarum parvitate vel multiplicitate, aut thiaris plumaceis insignes, uropygio carentes, flavipedes, plumipedes; habentur toto corpore reversis plumis hirsutæ; immo in India nascitur va-*

rietas, plumis lanuginosis albis vestita, et cute per totum corpus nigra. Et hæc omnes, exceptis Indicis, innumera colorum diversitate ludunt." Pallas, *Spicileg. Zool. fasc. 4.*

The formation of new varieties by breeding from individuals, in whom the desirable properties exist in the greatest degree, is seen much more distinctly in our domestic animals, than in our own species, since the former are entirely in our power. The great object is to preserve the race pure, by selecting for propagation the animals most conspicuous for the size, colour, form, proportion, or any other property we may fix on, and excluding most carefully all others. In this way we may gain sheep valuable for their fleece, or for their carcase; large or small; with thick or thin legs; just such, in short, as we chuse, within certain limits. (See BREEDING and CATTLE.) The importance of this principle is fully understood in rearing horses and cocks. The Arabian preserves the pedigree of his horse more carefully than his own, and never allows any ignoble blood to be mixed with that of his valued breeds: he attests their unfulfilled nobility by formal depositions and numerous witnesses. (See Buffon on the Horse.) The English breeder knows equally well that he must vary his stallions and mares according as he wishes for a cart horse, a riding horse, or a racer; and that a mistake in this point would immediately frustrate his views. Blood is equally important in the cock; and the introduction of an inferior individual would inevitably deteriorate the properties of the offspring.

Stature.—No part of our subject has been more disgraced by fables and hyperbolic exaggeration than the present division. Not to mention the pigmies and giants of antiquity; the bones of different large animals, ascribed to human subjects of immoderate stature, even by such men as Buffon, sufficiently prove our assertion. The accuracy of modern investigation has, however, so completely exposed the extravagance of such suppositions, that we are relieved from the necessity of a detailed consideration. All the remains of antiquity, which afford us any inferences on the subject of stature, such as mummies, human bones, and particularly teeth taken from the oldest burial places and urns, armour, &c. concur in proving that the ancients did not exceed the moderns in this respect. Yet amongst the latter there are obvious national differences. Of European nations some parts of Sweden and Switzerland are distinguished for tallness, as Lapland is in the contrary respect. The Abipons in the new world are of large size, and the Esquimaux small; but neither are very remarkable: and there is no difference between any two modern nations, but what admits of easy explanation on the common causes of degeneration, and the analogous phenomena furnished by the natural history of other animals.

The Patagonians (so called from its being supposed that they were allied to a neighbouring people, the Chonos, and from their resembling hairy-footed animals, called in Spanish Patas, through their practice of wearing the rough skin of the guanaco) or, according to their own indigenous name, the Tehuels, which occupy the south-east part of the extremity of South America, seem to be the tallest of the human race; but their height has been much exaggerated. Pigafetta, who accompanied Magalhaens on his voyage round the world, asserted that they were twice as tall as Europeans, (*Viaggio attorno il Mondo, in the collection of Ramusio, vol. i.*) From that time for two centuries and a half, the narratives of European voyages into that part of the world, are so strangely contradictory and inconsistent with each other, on the subject of these Patagonians, that they afford a lesson inculcating most strongly the necessity of

caution and diffidence in employing such reports. Blumenbach cites ten authors in illustration of this point (*De Varietate* p. 255). It is sufficient, for our present purpose, to represent what appears the most probable state of the case, after weighing and critically considering the most unexceptionable testimonies. They seem in truth to be a tall, though not gigantic race, and to possess a remarkably muscular frame. Thus at least they are represented by the most respectable observers. The only Patagonians ever seen in Europe, were brought to Spain towards the end of the 16th century, and seen at Seville by the truly classical traveller Van Linschoten, who says that they were "well formed and large in the body," (*wel gestatuert ende grof van leden*.) The variety in the statements makes it difficult to assign any particular height; but they probably do not exceed six feet six inches English. Bougainville says that none were under five feet six inches, and none over five feet eleven inches, (*Paris measure*, of which the foot is to that of England as 144 to 135.) (*Voy. autour du Monde*, 4to. p. 126.) Commerçon, however, makes some of the highest six feet four inches (*French*). (*Journal Encyclopedique*, 1772.) Byron represents them as seven feet high; but he did not measure them: (*Hawkeſworth's Collection*, vol. i. p. 28.) Wallis, who measured them carefully, found the general stature to be six feet, (*Ibid.* p. 374;) and the statement of Carteret coincides with this; *Phil. Transact.* vol. lx. The stature we have assigned to these people is not so very remarkable, since other native tribes of the same continent have been noticed for their height: for example, the Caribs of Cumana, seen by Humboldt. As they are a wandering race, we cannot be surprised at finding that Europeans visiting the coast have not always been able to see them. The accounts of travellers prove, that the height of the Patagonians is not a peculiar circumstance. Bartram represents the *Muscogulges* and *Cherokees* of North America, inhabiting between 31° and 35' of North latitude, as taller than Europeans; many being above six feet, and few under five feet eight or ten inches. (*Travels*, p. 482.) The *Caffres*, according to Barrow, are "tall, robust, and muscular, and distinguished by a peculiar firmness of carriage; some of them were six feet ten inches, and so elegantly proportioned that they would not have disgraced the pedestal of the *Farnese Hercules*. We may perhaps regard the Patagonians, like the antient Germans, as a peculiar and genuine race, not modified or disturbed by intermixture with others. Large body and limbs, as well as undaunted courage, were the attributes of this people, according to *Pomponius Mela*; "immanes animis & corporibus," lib. iii. cap. 3. *Cæsar* and *Tacitus* corroborate this statement. By collecting and comparing all the notices concerning them in the writers of antiquity, we should be warranted in assigning to them a height of six feet three inches and a half (*French*), which at least equals the stature of the *Tehuels*. The *Laplanders* and *Nova Zemblians* in Europe, the *Samoieds*, *Oliacs*, *Yakuts*, and *Tungooses* in Asia, and the *Greenlanders* and *Esquimaux* of America, all, in short who inhabit high northern latitudes, are short in stature, measuring from four to five feet; and they agree remarkably in other characters, although occupying such distant countries. It seems rather doubtful whether the miserable *Pecherai*s, who wander naked over the rocks of *Terra del Fuego*, are also diminutive; but *Barrow* informs us that the *Boshmen* who adjoin the Cape, scarcely ever exceed four feet nine inches.

The nation of dwarfs in the interior of *Madagascar*, called *Quimos* or *Kimos*, seems to be only an exaggeration founded on the observation of a morbid individual. *Commerçon* mentions that he measured one who was only three

feet eight inches. (*Journal Encyclopedique* 1772.) It appears that the captain of the ship purchased a poor pallid dwarf, whose hands reached to her knees. That she had a head disproportionately large, uttered only indistinct sounds, and was quite stupid. From these circumstances *Blumenbach* conjectures that it was a case of *Cretinism*, and similar to the instances in *Salzburg*, the *Valais*, and particularly in *Piedmont*. *De Variet.* p. 261. *Handbuch der Naturgeschichte*, p. 65.

Every one will immediately perceive that the differences of stature in the human race are not equal to those occurring in different breeds of animals. The pigs taken from Europe into the island of *Cuba* have grown to twice their original size; and the cattle in *Paraguay* have experienced a great increase in this respect. *Clavigero*, *Storia antica del Messico*, t. iv. p. 142.

It is hardly necessary for us to mention the contrast between the small *Welch* and the huge cart horses, or the *Flanders* breed of these animals; and between the *Welch* and *Holstein* cattle. The *Paduan* fowl is twice the size of the common breed. *Buffon*, vol. xii. p. 112.

Fabulous Varieties.—Nations with bodies of variously monstrous configuration, as the *Arimaspi* with one eye, the *Monoceli* with one leg, the *Cynomolgi* with dogs' heads, &c. have been enumerated by cosmographers from the time of *Herodotus*, from various authorities, particularly *Aristeus*, *Ctesias* and *Megasthenes*. See *J. A. Fabricius de Hominibus nostri Orbis Incolis*, Hamb. 1721, 4to. It is not necessary to dwell on these fables, although we should probably find, as in other instances in natural history, that they consist of some truth, either hyperbolically exaggerated, or changed by absurd misrepresentation. We shall only speak of one out of this mass of prodigies, *viz.* the men with tails who have been again and again noticed by many authors of very different ages. Their last patron was *lord Monbodo*, in his *Origin and Progress of Language*, v. i. p. 234, and *Antient Metaphysics*, v. iii. p. 250.

Pliny in the first instance, and after him *Ptolemy* and *Pausanias*, speak of a nation in *India* with tails: we meet with them again in the middle ages in the *Nubian Geographer*; in *Marco Polo* the *Venetian*, and others: in more recent times such men are mentioned in the islands of the *Indian archipelago*, in some provinces of *Russia*, and in other places. Most of these accounts are derived from others, and not from ocular testimony; most of the reporters obviously deserve very little credit (the work of the *Swede*, for instance, who speaks of the tails of the *Nicobar* people, and is mentioned as a narrative "summæ fidei" in a letter of *Linnæus* to *lord Monbodo*, is characterised by *Blumenbach* as "ineptarum fabellarum plenissima"); and they differ most marvellously from each other (three eyewitnesses, who speak of the tails of the *Formosans* give quite different descriptions, see *Blumenbach de Variet.* p. 269, note *m.*) On the other hand the most intelligent and accurate travellers either make no mention of the prodigy, or else characterize it as a pure fiction. Some indeed have shewn what has given rise to the statement, as a pendulous portion of the dress in the *Nicobar* isles, see *Fontana* in the *Asiatic Researches*, v. iii. p. 151; or the mistake of a figure of a tailed and anthropomorphic simia. *Blumenbach* traced the engraving of such an animal through various authors, each of whom made it a little more human, until it was metamorphosed into the representation of a *homo caudatus*. *Martini* in his version of *Buffon* took a plate from the *Amazitates* of *Linnæus*, who took it from *Aldrovandus*, who took it from *Gesner*, who took it from a German description of the *Holy Land*, (*Reyfs in das gelobte land*, *Mentz*, 1486,) in which it represents a quadrumanous

manous monkey, which, with other exotic animals, was seen in the journey. (De Variet. p. 271, note p.) Thus, instead of having any race of men with tails authenticated by credible witnesses, there is no example even of a single family displaying such an anomaly, although there are many well-known instances of families with six fingers.

Monstrous Varieties.—These occur only in individual instances, and are probably to be regarded as pathological phenomena: their description is referred altogether to the article MONSTER.

Faculties of the Mind; and moral Feelings.—The different progress of various nations in general civilization, and in the culture of the arts and sciences, the different characters and degrees of excellence in their literary productions, their varied forms of government, and many other considerations, must convince us beyond the possibility of doubt, that the races of mankind are no less characterized by diversity of mental endowments, than by those differences of organization, which we have already enumerated and considered. Such however has been the effect of education, of laws, of peculiar habits and customs, and of the different forms of government in modifying the mind and character of men, that we can hardly now discern what should be ascribed to original difference, and what should be referred to the operation of these external causes. That climate will exert a powerful influence on the mind may be very reasonably expected; and it has an analogous influence on the animal creation. We are informed, that the dog in Kamtschatka, instead of being faithful and attached to his master, is malignant, treacherous, and full of deceit. He does not bark in the hot parts of Africa nor in Greenland; and in the latter country loses his docility so as not to be fit for hunting.

Yet, without denying that there are differences both in the extent and kind of mental power, we are decidedly of opinion that these differences are not sufficient in any instance to warrant us in referring a particular race to an originally different species; and we protest especially against the sentiments of those, who would either entirely deny to the Africans the enjoyment of reason; or who ascribe to them such vicious, malignant, and treacherous propensities as would degrade them, even below the level of the brute. It can be proved most clearly, and the preceding observations will suffice for this purpose, that there is no circumstance of bodily structure so peculiar to the Negro, as not to be found also in other far distant nations; no character which does not run into those of other races, by the same insensible gradations as those which connect together all the varieties of mankind. We cannot but admire the reasoning and humanity of those, who, after tearing the African from his native soil, carrying him to the West Indies, and dooming him there to perpetual labour, complain that his understanding shews no signs of improvement, and that his temper and disposition are incorrigibly perverse, faithless, and treacherous. Let us however observe him in a somewhat more favourable state than in those dreadful receptacles of human misery, the crowded decks of the slave-ship, or in the less openly shocking, but constrained and extorted, and therefore painful, labours of the sugar plantation. That the negroes are much like Europeans, and behave to others according to the treatment which they receive, may be easily gathered from the best sources of information. They have not indeed reached that sublime height, the "beau idéal" of morality, the returning good for evil, probably because their masters have not yet found leisure enough from the pursuit of riches to instil into them the true spirit of Christianity. "The feelings of the Negroes are extremely acute.

According to the manner in which they are treated, they are gay or melancholy, laborious or slothful, friends or enemies. When well fed, and not mal-treated, they are contented, joyous, ready for every enjoyment; and the satisfaction of their mind is painted in their countenance. But, when oppressed and abused, they grow peevish, and often die of melancholy. Of benefits and abuse they are extremely sensible, and against those who injure them they bear a mortal hatred. On the other hand, when they contract an affection to a matter, there is no office, however hazardous, which they will not boldly execute, to demonstrate their zeal and attachment. They are naturally affectionate, and have an ardent love for their children, friends, and countrymen. The little they possess they freely distribute among the necessitous, without any other motive than that of pure compassion for the indigent." Hist. des Antilles, p. 483.

The travels of Barrow, le Vaillant and Mungo Park, abound with anecdotes honourable to the moral character of the Africans, and proving that they betray no deficiency in the amiable qualities of the heart. One of these gives us an interesting portrait of the chief of a tribe: "His countenance was strongly marked with the habit of reflection; vigorous in his mental, and amiable in his personal qualities, Gaika was at once the friend and ruler of a happy people, who universally pronounced his name with transport, and blessed his abode as the seat of felicity." Many highly polished European kings would appear to little advantage by the side of this savage. We see no reason to doubt that the negroes, taken altogether, are not inferior to any variety of the human race in natural goodness of heart. It is consonant to our experience of mankind in general, that the latter quality should be deadened or completely extinguished in the slave ship or the plantation: indeed it is as little creditable to the head as to the heart of their white tormentors to expect affection and fidelity from slaves after such treatment.

The acute and accurate Barbot, in his large work on Africa, says, "The blacks have sufficient sense and understanding, their conceptions are quick and accurate, and their memory possesses extraordinary strength. For, although they can neither read nor write, they never fall into confusion or error in the greatest hurry of business and traffic. Their experience of the knavery of Europeans has put them completely on their guard in transactions of exchange; they carefully examined all our goods, piece by piece, to ascertain if their quality and measure are correctly stated; and shew as much sagacity and clearness in all these transactions, as any European tradesman could do." Of those imitative arts, in which perfection can be attained only in an improved state of society, it is natural to suppose that the Negroes can have but little knowledge; but the fabric and colours of the Guinea cloths are proofs of their native ingenuity; and, that they are capable of learning all kinds of the more delicate manual labours, is proved by the fact, that nine-tenths of the artificers in the West Indies are Negroes: many are expert carpenters, and some watch-makers. The drawings and busts executed by the wild Boshman in the neighbourhood of the Cape are praised by Barrow for their accuracy of outline, and correctness of proportion.

Instances are by no means rare, of negroes, who have distinguished themselves in literature and the arts, when favoured by fortune with opportunities of education and improvement. In proof of their musical talents, it may be mentioned that they have been known to earn so much in America, as to purchase their freedom with large sums. The younger Freidig in Vienna was an excellent performer both on the violin and violoncello; he was also a capital draftsman, and had made a very successful painting of himself.

The capacity of the negroes for the mathematical and physical sciences, is proved by Hannibal, a colonel in the Russian artillery, and Lislet of the isle of France, who was named a corresponding member of the French academy of Sciences, on account of his excellent meteorological observations. Fuller of Maryland was an extraordinary example of quickness in reckoning. Being asked in a company, for the purpose of trying his powers, how many seconds a person had lived who was 70 years and some months old, he gave the answer in a minute and a half. On reckoning it up after him, a different result was obtained; have not you forgotten the leap years? says the negro. This omission was supplied, and the number then agreed with his answer.

Boerhaave and De Haen have given the strongest testimony that our black brethren possess no mean insight into practical medicine; and several have been known as very dextrous surgeons. A negress at Yverdun is mentioned by Blumenbach as a celebrated midwife of real knowledge and a fine experienced hand.

Omitting Madocks a methodist preacher, and not attempting to enumerate all the negroes who have written poems, we may mention that Blumenbach possesses English, Dutch, and Latin poetry by different negroes. In 1734, A. W. Amo, an African, from the coast of Guinea, took the degree of doctor in philosophy at the university of Wittemberg. Two of his dissertations, according to Blumenbach, exhibit much well digested knowledge of the best physiological works of the time. In an account of his life, published at the time, by the academic council, his integrity, talents, industry, and erudition, are very highly commended.

Jac. Eliza Joh. Capitein, who was bought by a slave dealer, when eight years old, studied theology at Leyden, and published several sermons and poems; his "*Dissertatio de Servitute Libertati Christianæ non contraria*," went through four editions very quickly. He was ordained in Amsterdam, and went to Elmina on the Gold coast, where he was either murdered, or exchanged for the life and faith of his countrymen those he had learned in Europe.

Ignatius Sancho, and Gustavus Vasa, the former born in a slave ship on its passage from Guinea to the West Indies, and the latter in the kingdom of Benin, have distinguished themselves as literary characters in this country in modern times; their works and lives are so well known, and so easily accessible, that it is only necessary for us to mention them.

Blumenbach, from whose "*Beyträge zur Naturgeschichte*," the preceding instances are taken, sarcastically observes, that entire and large provinces of Europe might be named, in which it would be difficult to meet with such good writers, poets, philosophers, and correspondents of the French academy; and, on the other hand, that there is no savage people, which have distinguished themselves by such examples of perfectibility and even capacity for scientific cultivation; and consequently that none can approach more nearly to the polished nations of the globe, than the negro, p. 118.

The opportunities of observation, that fall to the lot of any individual, are so limited, and the remarks of travellers and historians so likely, from various causes, to be perverted by ignorance or misrepresentation, that it must be very difficult to produce any thing satisfactory on the subject of the general characters of the various races in intellect, disposition, &c. We present therefore to the reader the conclusions which are drawn by Meiners, from an immense collection of authorities.

"Providence bestowed on the white and handsome races, not only considerable prerogatives of bodily structure, but also of mental power; connecting however neither of them

with the finest climates. The ancients observed that the most fruitful countries weakened the powers of the mind and the manly virtues. The favourable influence of climate on the intellect cannot be denied; and it is equally true that the noblest natures would be unavoidably corrupted and degraded in certain situations. The most dangerous are certain spots on the coast of Africa, Egypt, Hindoostan, the southern Asiatic kingdoms, particularly Siam, China, and several islands, the West Indies, and various spots in South America. An almost incredible acuteness of the external senses, which seems a gift of nature, is found in the dark and ugly nations. Among savages, as well as among the civilized, remarkable examples occur of men, who are not moved by the most violent impressions, and yet cannot bear the mildest perfume. In the ugly nations, an almost entire insensibility to beauty of form, order, and harmony, is united to the greatest acuteness of the senses. It seems that their imagination has a peculiar turn, which does not exist in the handsome nations.

The whole division of the ugly and dark coloured people is far below the white and handsome ones in the faculties of the mind; yet there are considerable differences between the various races in both. In Asia the Burates are the most stupid; the Calmucks are more docile; and some southern people, as those of Pegu, the Malays, Chinese, and Japanese are much more so. This want of talents affects also the lower castes of the Hindoos. The original inhabitants of America possess still less intellect than the Mongolian tribes of Asia, and this is an incontrovertible proof that climate may rob the human race of genius and virtue. The stupidity of the Americans was so striking, and so generally known, that there was some trouble to convince the Spaniards that they were men, and capable of becoming christians; yet these very Americans display, in certain points, a capability of learning, by which they exceed the most ingenious Europeans. The negroes indeed come above the Americans; but they are nearer to them than to the Europeans. Of the white people, the Celtic race has been much more richly endowed by nature, than the Slavonic or Oriental.

The dark people are again distinguished from the fair by a deplorable absence of virtues, and by several frightful excesses. With an irritability arising from weakness, and an incredible sensibility to the slightest affronts, the black nations combine an astonishing insensibility of the pains and joys of others, even their nearest relations, inflexible cruelty, selfishness and disposition to cheat, and a want of all sympathetic impulses and feelings. With more than female cowardice, and fear of open approaching danger and death, they join inconceivable calmness and indifference under the most horrible tortures, diseases, and actual death; with want of affection towards their own children, an extraordinary degree of tenderness to animals, even the most disgusting vermin; with brutal obscenity, voracity, and shamelessness, either an immoderate attachment to sensual love, or the greatest coldness, and consequent contempt of the female sex. Excessive irritability is found in all the Finnic races of Asia and America. The Burates are the worst of all these savages, and are considerably excelled by the Tungooses, the Calmucks and Monguls, the Coriacks, the Tschutski, the Kuriles, and particularly the Japanese. The Kamtschatkans are more contemptible, but less cruel than the Laplanders. The Chinese are one of the most worthless people in Asia, and are exceeded in integrity at least, if in no other respect, by the Tunquinese, Siamese and Hindoos. The Malays, and most of the people who descend from them, are feared, not only by the Asiatics, but even by the Europeans. The souls of the blacks in New Guinea, New Holland,

Holland, &c. are not less ugly than their bodies; on the contrary, the disposition alone of the inhabitants of the Nicobar and Bally islands would prove that they are of more noble origin than their neighbours. The worthlessness or corruption of human nature is no where more universal, or has been more accurately observed, than in the Americans, the portraits of whom, fill the friend of humanity, by turns, with pity, horror, and indignation. The dispositions of the negroes are as different as their descent; hence the contradictory descriptions of their manners. Even the slave dealers fix their prices, not merely according to the bodily powers, but in proportion to the docility and good dispositions of their commodity. The worst negroes of Malabaric origin are the Jagas, the Anzicos, those of Dahomey, and the Gallas, which, as well as all their black brethren, bear a remarkable resemblance in disposition to the Americans.

"The white and handsome nations may degenerate and be reduced to a state of barbarism by physical and moral causes, as we learn from the examples of the Greeks and Romans, of the modern inhabitants of Caucasus and almost all the European colonies in the torrid zone. But they have distinguishing prerogatives in their wildest state, as a comparison of the ancient Germans, Spaniards, Scandinavians, and Scythians, and of the modern Highland Scotch, and other Celtic people, with the African and American savages, will most abundantly prove. The Celtic people alone have possessed true bravery, love of liberty, and other passions and virtues of great souls. They alone have been as generous and mild towards the weak and the vanquished, as terrible to their enemies; and have constantly treated conquered nations and the female sex very differently from the Mongolians. Most of the virtues, which adorn and ennoble man, have existed from early times in a higher degree among the Celtic than among the Slavonic and Oriental people. The white people are neither so debauched, nor so cold, nor so much addicted to unnatural enjoyments as the dark coloured. On the other hand, the Slavonics and Orientals have a much stronger attachment to sensual love than the Celts; and of the latter, the southern are more sensual than the northern. Some savages indeed have conceived themselves superior to Europeans; but, in general, they have acknowledged the excellence of these more noble races, and this confession is most plainly implied in the practice of offering their wives and daughters to better men, and in the attachment and fidelity, which the women of the ugly nations display towards the more powerful Europeans, in preference to the men of their own race." Meiners, *Grundriss*, p. 111. 128.

Causes of the Varieties of the Human Species.—The causes which operate on the bodies of living animals, either modify the individual, or alter the offspring. The former are of great importance in the history of animals, and produce very astonishing alterations in their nature; but the latter are the most powerful, affect the species, and create the diversities of race or breed.

Climate.—That climate will exert a very powerful influence on all organized bodies, and particularly on warm blooded animals, must naturally be expected, when we consider how constantly and completely these animals are exposed to the action of the atmosphere in which they live; how wonderfully the composition of this air, formerly supposed to be a simple element, varies, not only in its gaseous ingredients, but also in the accessory ones of light, heat, electricity, &c.; and what a variety of other circumstances is to be taken into consideration, as the geographical position of different countries, their elevation, mountains, rivers, vicinity to the sea, prevailing winds, &c. Let it be further re-

membered, that the blood exposed to this air in the chest must be variously changed according to its composition and nature, and thus that the secretions, as well as the function of nutrition, of which the materials are derived from this fluid, must be greatly influenced.

Although this considerable and constant operation of climate on the animal economy, and the habit and form of the body has been noticed by attentive observers in all ages, it is rather difficult to define precisely what ought to be attributed to this cause only, and what arises from the other sources of degeneration, or from their concurrence. We shall state one or two changes, which seem to depend unequivocally on this cause.

The whitening (blanching or etiolation) of vegetables, when the sun's rays are excluded, demonstrates the agency of those rays on vegetable colours. In the same way, men who are much exposed to the air acquire a deeper tint in their skin than those who are more covered; and the tanning of the skin by the summer sun in parts of the body exposed to it, as the face and hands, is a phenomenon completely analogous. The ruddy and tawny hues of those who live in the country, and the pale fallow countenances of the inhabitants of towns owe their origin to this cause. Men of the same race are lighter or darker coloured according to the climate which they inhabit; the Moors, in their native colour, are not darker than the Spaniards, French, nor most of the English; but their acquired tint is so much deeper, that we distinguish them instantly. How swarthy do the Europeans become, who seek their fortunes under the tropics and equator, and have their skins parched by the burning suns of "Afric and of either Ind."

The white colour, in the northern regions, of many animals which possess other colours in more temperate climates, as the fox, the hare, beasts of burden, the falcon, crow, jackdaw, chaffinch, &c. seems to arise entirely from climate. This opinion is strengthened by the analogy of those animals, which change their colour, in the same country at the winter season, to white or grey, as the ermine and weasel, hare, squirrel, rein deer, white game (*tetrao lagopus*), snow bunting (*emberiza nivalis*), &c. *Linnaeus Flora Lapponica*; edit. of Smith, p. 55. 352. The common bear is differently coloured in different countries.

That the coverings of animals, as well as their colour, are much influenced by climate, is evinced in many instances. The sheep in Africa has a coarse hair substituted in the place of its wool; and the dog loses its coat entirely, and has a smooth and soft skin. The wool of the sheep is thicker and longer in the winter, and in hilly northern situations, than in the summer, and on warm plains. Much benefit is derived, in the cultivation of this animal, by changing its pastures according to the seasons of the year, and protecting it from the severity of the climate. The influence of various causes, which may be comprehended under the general term of cultivation, is very striking in the sheep and goat; the great difference in the wool produced from the former, under various circumstances, is well known; and a person, who was acquainted with the covering of the goat in European climates, would hardly believe it possible that the material from which the precious shawls of Cashmere are manufactured, could be produced from the same animal.

Whether the long and silky coat of the goat, cat, sheep, and rabbits of Angora can be ascribed to the climate, we do not know; it is at least worthy of notice that this quality of the hair should exist in so many animals. It continues when they are removed into other countries, and is transmitted to the offspring; so that we may probably regard these animals as permanent breeds.

Must

Must we not refer to climate the constant and remarkable degeneracy of the horse in France. "In France," according to Buffon, "Spanish or Barbary horses, when the breed is not crossed, become French horses, sometimes in the second generation, and always in the third." V. iv. p. 106.

Food.—We naturally expect that food will produce considerable changes in the living body; its effect seems to be proved by the well known fact that several singing birds, chiefly of the lark and finch kinds, become gradually black, if they are fed on hempseed only. (Blumenbach, de Variet. p. 94.) The texture of the hair has been changed, in an African sheep brought into England, from the coarse nature of that of the camel, to considerable fineness and softness, by one year's feeding in the pastures of this country. The influence of the same cause on the stature and proportion of the body is shewn in the horse, which grows to a large size in the marshy grounds of Friesland, while on stony soils, or dry heaths, they remain dwarfish. Oxen become very large and fat in rich soils, but are distinguished by shortness of the legs; while in drier situations, their whole bulk is less, and the limbs are stronger and more fleshy. We say nothing of the well-known differences of flavour and weight produced by different kinds of food.

Changes caused by Climate are temporary.—Two very different opinions have been maintained concerning these changes, produced by the action of external causes on the bodies of animals. Some, as Buffon, Blumenbach, Zimmermann, (Geographische geschichte der Menschen, &c.) contend that they are transmitted to the offspring, and thus cause varieties: others argue that the effect terminates in the individual; that the young animal is not in the slightest degree modified by it, but is born with the original properties, and constitution of the parents, and a susceptibility only of the same changes when exposed to the same causes. The latter opinion has been most ably defended in the inaugural dissertation of Dr. Prichard, Edinburgh, 1808, and seems to us to rest upon the most incontrovertible grounds.

The change in the colour of the human skin, from exposure to sun and air, is obviously temporary; for it is diminished and even removed when the causes no longer act. The discoloration, which we term tanning or being sun-burnt, as well as the spots called freckles, are most incidental to fair skins, and disappear when the parts are covered, or no longer exposed to the sun. The children of the husbandman or of the sailor, whose countenance bears the marks of other climes, are just as fair as those of the most delicate and pale inhabitant of a city: nay, the Moors, who have lived for ages under a burning sun, still have white children; and the offspring of Europeans in the Indies have the original tint of their progenitors. Blumenbach has been led into a mistake on this point by an English author (Hawkesworth, in Collection of Voyages, v. iii. p. 374), who asserts that Creoles are born with a different complexion and cast of countenance, from the children of the same parents brought forth in their native country. In opposition to this statement, from one who was not an eye-witness, we shall place the authority of Long, who, in his history of Jamaica, affirms "that the children born in England have not, in general, lovelier or more transparent skins, than the offspring of white parents in Jamaica." The "austum spirans vultus & color," which this acute and learned naturalist ascribes to the Creole, is merely the acquired effect of the climate, and not a character existing at birth.

"Nothing," says Dr. Prichard, "seems to hold true more universally, than that all acquired conditions of body, whether produced by art or accident, end with the life of the individual in whom they are produced. Many nations

mould their bodies into unnatural forms: the Indians flatten their foreheads (See CRANIUM); the Chinese women reduce their feet to one-third of their natural dimensions; savages elongate their ears; many races cut away the prepuce. We constantly mutilate our domestic animals by removing the tail or ears, and our own species are often obliged by disease to submit to the loss of limbs. That no deformity or mutilation of this kind is hereditary, is so plainly proved by every thing around us, that we wonder how the contrary opinion should have gained any advocates. After the operation of circumcision has prevailed for more than three thousand years, the Jews are still born with prepuces, and still obliged to submit to the painful rite. Docked horses and cropped dogs bring forth young with entire ears and tails. But for this salutary law, what a frightful spectacle would every race of animals exhibit! The mischances of all preceding times would overwhelm us with their united weight, and the catalogue would be continually increasing, until the universe, instead of displaying a spectacle of beauty and pleasure, would be filled with maimed, imperfect, and monstrous shapes."

The changes produced in the coverings of animals by external causes, and those brought about by food, are equally confined to the present race. If a breed with different qualities be required, other individuals, possessing those qualities, must be employed.

Permanent Varieties of Animals are only produced by Generation.—That the foregoing causes are not adequate to account for those more signal diversities, which constitute differences of race in animals, will be readily admitted. These can be explained only by native or congenital variety, as we have shewn in enumerating those points, in which men and animals differ. In the present state of physiological knowledge, we cannot attempt to shew how it happens that an offspring is produced, differing from the parents in some characters, which are conveyed by hereditary succession; how a grey rabbit or cat shall bring forth at one birth, and from one father, yellow, black, white, and spotted young; how a white sheep shall have a black lamb; or the same parents, Leucæthiopic and ordinary children at different times. In short, in considering all the circumstances under which animal bodies are influenced by external agents, we must be contented with stating the facts that prove the influence of such causes, without attempting to explain how they produce their effects. As there is so little of a satisfactory nature ascertained on this head, we should be afraid of disgusting the sensible reader, by substituting speculation in the place of more solid information.

Influence of Mode of Life in producing Varieties.—The state of domestication, or the artificial mode of life, which they lead under the dominion of man, is the most powerful cause in favouring the production of varieties in the animal kingdom. Wild animals, using always the same kind of food, being exposed to the action of the climate without fire or artificial covering, chuse, each of them according to its nature, their zone, and country: instead of dispersing themselves, like man, they continue in those places, which are the most friendly to their constitutions. Hence their nature undergoes no change; their figure, colour, size, proportion, &c. are unaltered; and there is consequently no difficulty in determining their species. But, says Buffon, when forced by man, or by any revolution on the globe, to abandon their native soil, their nature undergoes changes so great, that, to recognize them, recourse must be had to accurate examination, and even to experiment and analogy. If to these natural causes of alteration in free animals, we add that of the empire of man over those which he has reduced to slavery, we shall

shall be astonished at the degree to which tyranny can degrade and disfigure nature; we shall perceive the marks of slavery, and the prints of her chains; we shall find that those wounds are deeper and more incurable in proportion to their antiquity: and that, in the present condition of domestic animals, it is, perhaps, impossible to restore their primitive form, and those attributes of nature, which we have taken from them." vol. iv. p. 6. To trace back our domestic animals to their wild originals, is in all cases difficult, in some impossible: long slavery has so degraded their nature, that the primitive animal may be said to be lost, and a degenerated being, running into endless varieties, is substituted in its place. The wild original of the sheep was for a long time unknown: Buffon conceived that he discovered it in the mouflon or argali (*ovis ammon*); and Pallas, who had an opportunity of studying this animal, adds the weight of his highly respectable authority to the opinion of the French naturalist. Yet, Blumenbach regards the argali as a distinct species. Should we allow the latter to be the parent of our sheep, and consequently admit that the differences are explicable by degeneration, no difficulty can any longer exist about the unity of the human species. An incomplete horn of the argali, in the academical museum at Göttingen, weighs nine pounds. Blumenbach, *handbuch der Naturgeschichte*. p. 111, note.

"Let us compare," says Buffon, "our pitiful sheep with the mouflon, from which they derived their origin. The mouflon is a large animal. He is fleet as a stag, armed with horns and thick hoofs, covered with coarse hair, and dreads neither the inclemency of the sky, nor the voracity of the wolf. He not only escapes from his enemies by the swiftness of his course, and scaling, with truly wonderful leaps, the most frightful precipices; but he resists them by the strength of his body, and the solidity of the arms with which his head and feet are fortified. How different from our sheep, which subsist with difficulty in flocks, who are unable to defend themselves by their numbers, who cannot endure the cold of our winters without shelter, and who would all perish, if man withdrew his protection. So completely are the frame and capabilities of this animal degraded by his association with us, that it is no longer able to subsist in a wild state, if turned loose, as the goat, pig, and cattle are. In the warmest climates of Asia and Africa, the mouflon, who is the common parent of all the races of this species, appears to be less degenerated than in any other region. Though reduced to a domestic state, he has preserved his stature and his hair, but the size of his horns is diminished. Of all domestic sheep, those of Senegal and India are the largest, and their nature has suffered least degradation. The sheep of Barbary, Egypt, Arabia, Persia, Tartary, &c. have undergone greater changes. In relation to man, they are improved in some articles, and vitiated in others; but, with regard to nature, improvement, and degeneration are the same thing; for they both imply an alteration of original constitution. Their coarse hair is changed into fine wool. Their tail, loaded with a mass of fat, (and sometimes reaching the weight of 40 pounds), has acquired a magnitude so inconvenient, that the animals trail it with pain. While swollen with superfluous matter, and adorned with a beautiful fleece, their strength, agility, magnitude, and arms are diminished: these long-tailed sheep are half the size only of the mouflon. They can neither fly from danger, nor resist the enemy. To preserve and multiply the species, they require the constant care and support of man. The degeneration of the original species is still greater in our climates. Of all the qualities of the mouflon, our ewes and rams have

5†

retained nothing but a small portion of vivacity, which yield to the crook of the shepherd. Timidity, weakness, resignation, and stupidity, are the only melancholy remains of their degraded nature." Vol. iv. p. 7.

It will naturally be expected that degeneration has operated most deeply and variously on those domestic animals which man has subjected for many ages, and so completely, that they propagate in their enslaved condition; not on those, of whom each individual is brought into captivity from his wild state, as the elephant; nor on such as have not been taken into foreign climates, as the rein-deer, which is confined to a very limited portion of the globe. The pig is a good example, because his descent is more clearly made out than that of many others. The dog indeed degenerates before our eyes, but it will hardly ever, perhaps, be ascertained whether there is one or more species. The extent of degeneration can be observed in the domestic pig, because, we believe, no naturalist has hitherto been sceptical enough to doubt whether he descended from the wild boar, and he was certainly first introduced by the Spaniards into the New World. The pigs conveyed, in 1509, from Spain to the West India island Cubagua, then celebrated for the pearl fishery, degenerated into a monstrous race with toes half a span long. Herrera, *hechos de los Castellanos en las Islas, &c.* (vol. i. p. 239.) Those of Cuba became more than twice as large as their European progenitors: *Clavigero, storia antica del Messico.* (vol. iv. p. 145.) How remarkably again have the domestic swine degenerated from the wild ones in the old world; in the loss of the soft downy hair from between the bristles, in the vast accumulation of fat under the skin, in the form of the cranium, in the figure and growth of the whole body. The varieties of the domestic animal too are very numerous: in Piedmont they are almost invariably black; in Bavaria reddish-brown, in Normandy white, &c. The breed in England with straight back and large pendulous belly is just the reverse of that in the North of France, with high convex spine, and hanging head; and both are different from the German breed; to say nothing of the solid-ungular race found in herds in Hungary and Sweden, and already known by Aristotle, and many other varieties.

The ass, in its wild state, is remarkably swift and lively, and still continues so in his native countries in the East; the bison, or wild ox, has a long flowing mane, hanging almost to the ground.

The original stock of our poultry cannot be determined, nor can the varieties into which they have run be enumerated. No wild bird in our climates resembles the domestic cock: the pheasant, grouse, and wood-hen, are the only analogous kinds; and it is uncertain whether these would intermix, and have prolific progeny. They have constituted distinct and separate species from the earliest times; and they want the combs, spurs, and pendulous membranes of the gallinaceous tribes. Buffon, vol. xii. p. 112.

There are twenty-nine varieties of canary birds known by name, all produced from the grey bird. Buffon, vol. xiv. p. 61.

Most of the mammalia, which have been tamed by man, betray their subjugated state by having the ears and tail pendulous; a condition of the former parts which, we believe, belongs to no wild animal. In many, the very functions of the body, as the secretions, generation, &c. are greatly changed. The domestic sow produces young twice a year; the wild animal only once; it frequently brings forth monstrous fetuses, and is invaded by a new species of hydatids, forming what is called the measles in pork.

A good hen, well supplied with food, lays 100 eggs between

tween spring and autumn; in the wild state the only produces eighteen or twenty. Buffon, vol. ii. p. 30.

The application of these facts to the question concerning the human species is very obvious. If domesticated animals vary, because they have been taken from their primitive condition, and exposed to the operation of many, to them unnatural, causes; if the pig is remarkable among these for its varieties, because it has been the most exposed to causes of degeneration; we shall be at no loss to account for the diversities in man, who is, in the true, though not ordinary sense of the word, more of a domesticated animal than any other. We know the wild state of most of them; but we are ignorant of the natural wild condition to which man was destined. Probably there is no such state; because nature, having limited him in no respect, having fitted him for every kind of life, every climate, and every variety of food, has given him the whole earth for his abode, and both the organized kingdoms for his nourishment.

The numerous varieties of domestic animals, which are incontestibly the offspring of domestication, may be regarded as a refutation of the general position, which we lately laid down, that no acquired condition is transmitted by generation. These diversities are undoubtedly the strongest argument in favour of the changes produced by the way of life being hereditary; and we are not hitherto warranted in positively denying this. They admit of explanation, however, on another principle; *viz.* that the domestic state causes a disposition to the production of native varieties, which, as we well know, are hereditary. We know no direct observations, by which it can be decided that modifications of colour, form, &c. produced by external causes, are in no instance transmitted to the offspring, and that they are all first produced as native varieties in the course of generation. Analogy, however, very much favours this notion.

Such, then, are the causes by which the varieties of man may be accounted for. Although we have acknowledged our entire ignorance of the manner in which these operate, we have proved that they exist, and have shewn, by copious analogies, that they are sufficient to explain the phenomena. The tendency, under certain circumstances, to alterations of the original colour, form, and other properties of the body, and the law of transmission to the offspring, are the sources of varieties in man and animals, and thereby modify the species: climate, food, way of life, in a word, all the physical and moral causes that surround us, act indeed powerfully on the individual, but do not change the offspring, except in the indirect manner alluded to in the preceding paragraph. We should, therefore, openly violate the rules of philosophizing, which direct us to assign the same causes for natural effects of the same kind, and not to admit more causes than are sufficient for explaining the phenomena, if we recurred, for the purpose of explaining the varieties of man, to the perfectly gratuitous assumption of originally different species, or called to our aid the operation of climate, &c.

Yet, if it be allowed that all men are of the same species, it does not follow that they all descend from the same family. Some contend that all parts of the globe were furnished at first with men and animals, and lay great stress on the difficulty which the race would experience in extending over wide tracts, and gaining access to remote regions and islands. A reference to facts will shew us that these difficulties have been overcome. The numerous islands of the Pacific, in many instances very distant from each other, and from the continent, are inhabited by men of the same race; and we meet in Madagascar and Easter island, separated by nearly

half the globe, with men of the same origin, employing the same language. This view is confirmed by the very interesting facts first noticed by Buffon, that no animals are found in both continents, but such as are able to bear the cold of these regions where they probably join; and that not a single animal of the torrid zone is common to the old world and the new.

Consideration of the Opinion, which explains the Varieties of Mankind by the Operation of Climate. Statement of the Argument.—By the most intelligent and learned writers on the varieties of mankind, they have been explained altogether by the operation of adventitious causes, as climate, particularly the light and heat of the sun, food, and way of life. It has been considered that these, acting on men originally alike, produce various bodily diversities, and affect the colour of the skin especially; and that such alterations, transmitted to the offspring, and gradually increased through a long course of ages, account very sufficiently for all the differences observed at present in the inhabitants of the different regions of the globe. If we were inclined to submit in this question to authority, the number and celebrity of the philosophers, who have contended for the influence of climate, and other physical and moral causes, would certainly compel our assent to their opinions. Buffon, Blumenbach, Smith (Essay on the Causes of the Variety of Complexion and Figure in the human Species, Philadelphia), Zimmerman (Geographische Geschichte des Menschen, &c.) Ludwig (Grundriß der Naturgeschichte des Menschen-species, &c.), are only a few of those who have adopted and defended this view of the subject.

Opinion of Buffon.—"The heat of the climate," says Buffon, "is the chief cause of blackness among the human species. When this heat is excessive, as in Senegal and Guinea, the men are perfectly black; when it is a little less violent, the blackness is not so deep; when it becomes somewhat temperate, as in Barbary, Mongolia, Arabia, &c. mankind are only brown; and lastly, when it is altogether temperate, as in Europe and Asia, men are white. Some varieties, indeed, are produced by the mode of living. All the Tartars (Monguls), for example, are tawny; while the Europeans, who live under the same latitude, are white. This difference may safely be ascribed to the Tartars being always exposed to the air, to their having no cities or fixed habitations, to their sleeping constantly on the ground, and to their rough and savage manner of living. These circumstances are sufficient to render the Tartars more swarthy than the Europeans, who want nothing to make life easy and comfortable. Why are the Chinese fairer than the Tartars, though they resemble them in every feature? Because they are more polished; because they live in towns, and practise every art to guard themselves against the injuries of the weather: while the Tartars are perpetually exposed to the action of the sun and air.

"Climate may be regarded as the chief cause of the different colours of men: but food, though it has less influence than colour, greatly affects the form of our bodies. Coarse, unwholesome, and ill-prepared food makes the human species degenerate. All those people, who live miserably, are ugly and ill made. Even in France, the country people are not so beautiful as those who live in towns: and I have often remarked, that in those villages, where the people are richer and better fed than in others, the men are likewise more handsome, and have better countenances. The air and the soil have great influence on the figures of men, beasts, and plants.

"Upon the whole, every circumstance concurs in proving that mankind are not composed of species essentially different

ferent from each other; that, on the contrary, there was originally but one species, which, after multiplying and spreading over the whole surface of the earth, have undergone various changes by the influence of climate, food, mode of living, epidemic diseases, and mixture of dissimilar individuals; that, at first, these changes were not so conspicuous, and produced only individual varieties; that these varieties became afterwards more specific, because they were rendered more general, more strongly marked, and more permanent, by the continual action of the same causes; that they are transmitted from generation to generation, as deformities or diseases pass from parents to children; and that, lastly, as they were originally produced by a train of external and accidental causes, and have only been perpetuated by time, and the constant operation of these causes, it is probable that they will gradually disappear, or, at least, that they will differ from what they are at present, if the causes which produced them should cease, or if their operation should be varied by other circumstances and combinations." *Natural History*, by Wood, vol. iii. p. 443—446.

Opinion of Smith.—"In tracing the globe," says Smith, "from the pole to the equator, we observe a gradation in the complexion, nearly in proportion to the latitude of the country. Immediately below the arctic circle, a high and sanguine colour prevails: from this you descend to the mixture of red and white: afterwards succeed the brown, the olive, the tawny, and, at length, the black, as you proceed to the line. The same distance from the sun, however, does not, in every region, indicate the same temperature of climate. Some secondary causes must be taken into consideration, as correcting and limiting its influence. The elevation of the land, its vicinity to the sea, the nature of the soil, the state of cultivation, the course of winds, and many other circumstances, enter into this view. Elevated and mountainous countries are cool, in proportion to their altitude above the level of the sea, &c. &c." *Essay*, p. 8—10.

Opinion of Blumenbach.—Blumenbach informs us how climate operates in modifying the colour of the skin, but does not attempt to explain its effects on the stature, proportions, &c. He states that the proximate cause of the dark colour of the integuments is an abundance of carbone, fermented by the skin with hydrogen, precipitated and fixed in the rete mucosum by the contact of the atmospheric oxygen. (*De Variet.* p. 124.) He observes further, that this abundance of carbone is most distinctly noticeable in persons of an atrabilarious temperament; which fact, together with many others, proves the intimate connection between the biliary and the cutaneous organs; that hot climates exert a very signal influence on the liver; and thus, that an unnatural state of the biliary secretion, produced by heat, and increased through many generations, causes the vessels of the skin to secrete that abundance of carbone, which produces the black colour of the Negro. *Ibid.* p. 126—137.

Certain superficial Views favourable to this Opinion.—It cannot be supposed that men of undoubted talents and learning would take up these opinions without any foundation at all; and accordingly we find that there is a slender mixture of truth in these statements: but it is so enveloped in a thick cloud of error, and so concealed by misrepresentation and exaggeration, that we do not recognize it without difficulty. The colour of Europeans nearly follows the geographical positions of countries: this part of the world is occupied almost entirely by a white race, of which the individuals are fairer in cold latitudes, and more swarthy or sun-burnt in warm ones: thus, the French may be darker than the English, the Spaniards than the French, and the

Moors than the Spaniards. In the same way, where different parts of a country differ much in latitude and in temperature, the inhabitants may be browner in the south than in the north: thus, the women of Granada are said to be more swarthy than those of Biscay, and the southern than the northern Chinese, &c. These diversities are produced by the climate, as we have already explained. The effect goes off if the cause be removed: it terminates in the individual, and is never transmitted to the offspring, as we shall prove most incontrovertibly presently.

On a superficial view again, we observe that temperate Europe is occupied by a white race, and that the blacks, of whom we see and hear most, dwell chiefly under the burning suns and on the parched sands of Africa and Asia: the numerous whites who live in hot, and the greater number of dark coloured people who are found in cold countries, are not taken into the account in these imperfect and partial comparisons.

We are particularly surprised that the acuteness and good sense of Blumenbach should have allowed him to resort to an explanation grounded on such remote analogies, and so obviously weak and inadequate, as that by which he attempts to account for the black colour of the Negro. To require us to believe that all the dark coloured races labour under hepatic disease, when our senses inform us that they are in perfect health, is really too much: the statement is too absurd to require serious refutation.

Arguments against it.—We proceed to shew that climate does not cause the diversities of mankind; and in this consideration, our remarks are chiefly directed to the colour of the skin, as that is the part in which its operation has been regarded, by all the defenders of its influence, as the most unequivocal: the reasoning, however, will apply in general to the other points of difference, as well as to this.

The uniform colour of all parts of the body is a strong argument against those who ascribe the blackness of the Negro to the effect of the sun's rays. The glans penis, the cavity of the axilla, the inside of the thigh are just as black as any other parts; indeed, the organs of generation, which are always covered, are among the blackest parts of the body. Neither is the peculiar colour of the Negro confined to the skin; a small circle of the conjunctiva, round the cornea, is blackish, and the rest of the membrane has a yellowish-brown tinge. The fat has a deep yellow colour, at least in many of them, which could be distinguished by a very superficial inspection, from that of an European. On these points the testimony of Soemmering coincides with our own observation. (*Ueber die körperl. Versch.* § 7 and 46.) The species of domestic fowls in the East Indies, with black periosteum, affords a further proof that the operation of the sun's rays is not the cause of colour in animal bodies.

On the other hand, a black state of the skin is sometimes partially produced in individuals of the white races. In the fairest women, towards the end of pregnancy, spots of a more or less deep black colour have been often observed; they gradually disappear after parturition. "The dark colour of the skin," says White, "in some particular parts of the body, is not confined to either the torrid or frigid zones: for in England the nipple, the areola round the nipple, the pudenda, and the verge of the anus, are of a dark brown, and sometimes as black as in the Samoiede women. It is to be remarked that the colour of these parts grows darker in women at the full period of gestation. One morning I examined the breasts of twenty women in the lying-in hospital in Manchester, and found that nineteen of them had dark-coloured nipples; some of them might be said to be black, and the areola round the nipple, from one inch to

two inches and a half in diameter, was of the same colour. (On the regular Gradation, p. 114. Camper, *Kleinere Schriften*, vol. i. part i. p. 47.) Le Cat mentions a woman near Paris, in whom the abdomen became black at each pregnancy, and afterwards recovered its colour; in another the same change occurred in the leg. See Blumenbach de Variet. page 156, note z.

If we take the trouble of examining the races in any particular division of the world, we shall quickly find that the opinion, which ascribes their distinguishing characters to climate, must be given up; that the same race inhabits the most different regions, preserving in all an uniformity of character; that different races are found in the same countries, and that those, who have changed their native abodes for situations, in which, according to the hypothesis, they ought to have undergone a complete metamorphosis, still retain their original distinctions.

Arguments from the Races that occupy Europe.—In the north of Europe, as also in the north of Asia and America, that is, in countries nearest to the pole, in which, according to the opinion above stated, the whitest races ought to be found, we have very brown and black people: they are much darker coloured than any other Europeans. The Moors in Africa, and the Arabs of the desert are born with a white skin, and continue fair unless adventitious causes are applied. But the Laplanders and Greenlanders, who hardly ever feel a moderate heat from the rays of the sun, are all very dark. “The Laplanders,” says Buffon, “the inhabitants of Nova Zembla, the Borandians, the Samoieds, the northern Tartars, the Ostiaks of the old continent, and the Greenlanders and the savages to the north of the Eskimaux Indians in the new continent, appear to be all the same race, who have extended and multiplied along the coasts of the North sea, in deserts, and under climates which could not be inhabited by other nations. All these people have broad large faces, and flat noses. Their eyes are of a yellowish-brown colour, inclining to black; their eye-lids extend towards the temples: their cheek-bones are very prominent; their mouths are large, and their lips thick and reflected; the under part of their face is narrow; they have a squeaking voice; the head is large, the hair black and smooth, and the skin is of a tawny or swarthy hue. Their size is diminutive, but, though meagre, their form is squat. Most of them are only four feet high, and their tallest men exceed not four feet and a half” Vol. iii. p. 302.

It is curious to observe how easily the asserters of the power of climate in changing the human body get over an instance so fatal to their opinions: they tell us roundly that great cold has the same effect as great heat: “When the cold becomes extreme, it produces effects similar to those of violent heat. The Samoieds, Laplanders and natives of Greenland are very tawny; we are even assured that some of the Greenlanders are as black as the Africans; thus the two extremes approach each other: great cold and great heat produce the same effect upon the skin, because each of these causes acts by a quality common to both; and this quality is the dryness of the air, which, perhaps is equally great in extreme cold and extreme heat. Both cold and heat dry the skin, and give it that tawny hue which we find among the Laplanders. Cold contracts all the productions of nature. The Laplanders, accordingly, who are perpetually exposed to all the rigours of frost, are the smallest of the human species.” Buffon, vol. iii. p. 443. See also Smith's Essay.

If this reasoning should not convince us, there are other arguments in reserve. The state of society is said to have

great effect on the conformation and colour of the body. The nakedness of the savage, the filthy grease and paint with which he smears his body, his smoky hut, scanty diet, want of cleanliness, and the undrained and uncleaned country which he inhabits, not only, according to Smith, darken his skin, but render it impossible that it ever should be fair. (p. 48—52.) On the other hand, the conveniences of clothing and lodging—the plenty and healthful quality of food—a country drained, cultivated, and freed from noxious effluvia—improved ideas of beauty—the constant study of elegance, and the infinite arts for attaining it, even in personal figure and appearance, give cultivated an immense advantage over savage society in its attempts to counteract the influence of climate, and to beautify the human form. (p. 53.) What false notions must mankind have hitherto entertained on this subject! We can no longer believe travellers, who tell us that the finest forms, and the greatest strength are to be seen in savage tribes, and that no ill-formed individuals can be met with amongst them: and as little can we trust the testimony of our own senses, concerning the frequency of deformity and disease in civilized society; since there are so many reasons why the former should be deformed, black, and ugly, and the latter well proportioned, fair, and handsome. Unluckily, however, this fine-spun theory does not correspond with a few plain facts. Most of the modern European nations existed in a more or less complete state of barbarism within times of which we have the most authentic records: some of these were seen and described by philosophers; yet the permanence of their characters is so remarkable after a greater progressive civilization than has happened in any other instance, that those descriptions are applicable with the greatest exactness to the same races of the present day. Instead therefore of accounting for the dark colour, peculiar features, and stature of the Greenlander, Laplander, and Samoiede, from their smoke, their dirt, their food, or the coldness of the climate, we can have no hesitation in ascribing them to the same cause that makes the Briton and the German of this day resemble the portraits of their ancestors, drawn by Cæsar and Tacitus, viz. their descent from a race marked by the same characters as distinguish themselves. These tribes owe their origin to the Monguls, and retain in the north those marks of their descent, which we find as strongly expressed in the Chinese, under the widely different latitudes of the south. At the same time, the parent tribes live in the middle of Asia, equally removed from the former and the latter.

With slight exceptions, says Dr. Prichard, the different countries of Europe are now occupied by the same nations that have occupied them since the date of our earliest authentic accounts. Conquests have been made by small numbers, so that the races have been little changed by this cause. Thus when Clovis and his 30,000 Franks reduced the large and populous province of Gaul under their dominion, the bodily characters, and the language of the conquerors were lost in those of the conquered. The nations which have inhabited Europe for the last 2,500 years, consist of three great races, distinguished from each other by their bodily formation, character, and language.

1. The Celtic race, with black hair and eyes, and a white skin verging to brown, occupies the west of Europe: to this belong the ancient and modern inhabitants of France, Spain, Portugal, and the greatest part of Italy: the ancient Britons, Welsh, Bretons, Irish, Scotch, and Manks. The resemblance of the Silures to the Iberi was noticed by Tacitus; it is obvious to every observer in the present time; nor is the observation peculiar to the Welsh; it holds good

of all other Celtic nations. "Silurum colorati vultus, et torti plerumque crines, et posita contra Hispania, Iberos veteres trajecisse, easque sedes occupasse, fidem faciunt." That black hair and a browner complexion belonged to all the Celts, is not only proved by many direct observations, but also because the marks of the sanguine constitution were universally considered as the distinction of the German race.

2. The great German race, characterized by its blue eyes, yellow or reddish hair, fair and red skin, occupies the middle of Europe, and includes the Swedes, Norwegians, Icelanders, Danes, ancient and modern Germans, Saxons and English, Caledonians or Pictæ, and the Lowland Scotch, who have sprung from them, the inhabitants of the Low Countries, the Vandals and Goths, &c. Historical records, and the similarity of language and character both of body and mind, prove that all these people belong to the same race.

3. The east of Europe contains the Sarmatian and Slavonic tribes, characterized by dark hair and eyes, and a darker skin than the German, with perhaps larger limbs than the Celts. To this division belong the Russians, Poles, Croats, Slavons, Bohemians, Bulgarians, Cossacks, and others who speak the Slavonic language. (Diff. Inaug. de Variet. p. 102—109.) He proceeds to shew from Diodorus Siculus, that the Sarmatians descended from the Medes, and were found on the banks of the Tanais, 700 years before the Christian era: by the authority of Herodotus, that they occupied the country between the Tanais and the Borythenes, when Darius Hytaspes invaded Syria; and from Cluverius, that the coasts of the Baltic, the banks of the Vistula, Prussia, and the country as far as the situation of the Finni and Venedi, were the ancient seats of the Sarmatians. Since then a people of very different race have existed in the neighbourhood of the Germans from the most remote times, how can we explain the differences of the European nations, by the operation of climate, by heat and cold? How does the same sky cause the whiteness of the German and Swede, and the comparatively dark complexion of the Pole and Russian?

But these European races are found also in Asia and Africa. All that part of the former region, which lies to the west of the river Ob, the Caspian sea, and the Ganges; all the north of Africa, Abyssinia, and perhaps other parts still farther south, on the east, are occupied by a race agreeing nearly in character with the Sarmatians and Celts.

Thus it appears, that, excepting the Germans, and the Laplanders and Samoiedes, whom we deem of Mongolian origin, the same native or congenital constitution prevails over the whole of Europe, the western parts of Asia, and the north of Africa. Black hair, dark eyes, and a white skin, tending rather to a brownish tint, than to the peculiar whiteness of the German tribes, belong to the French, Spaniards, Portuguese, Italians, and all the Celts; to the Russians, Poles, and others of Slavonic origin; to the Tatars, commonly confounded with the Mongols, the Circassians and Georgians, the Turks, Greeks, Arabians, Abyssinians, Syrians, Jews, and the inhabitants of Tripoli, Tunis, Algiers and Morocco. That climate cannot be the cause of the identity of character in nations spread over fifty degrees of latitude, and that food, dress, state of civilization, peculiar customs, &c. are equally inefficacious in accounting for this sameness, when we consider how numerous and diversified the nations are in whom it occurs, will be allowed by every unprejudiced observer.

Asiatic Races.—Two races are to be found in Asia, on the

east of the Ob and the Caspian. "The vast tracts of mountains that stretch from the Caspian to the remotest borders of the east, have been occupied from time immemorial by the Mongolian tribes, distinct in their conformation from all other races, and more different from the Europeans than any negroes. Their skin varies from yellow-white to olive colour. Their hair is perfectly black from the time of birth. In stature they are short; they have round heads, large ears, oblique eyes, flat noses. To this nation the name of Tartars (Tatars) has been very improperly applied, as they have nothing in common with the true Tatars, who altogether resemble the Europeans. All the east of Asia, except a few spots occupied by Tatars and Ostiaks, the Tschutski, probably derived from the aborigines of America, and the Indians, contains several nations very closely resembling the Monguls, and arising in all probability from the same root. Among these we enumerate the Calmucks and Buriates, a part of the Mongolian nation itself, the Samoiedes, the Tungooses, the Mantchoos, who border on the Chinese, the Chinese themselves, the Jakuts, the Japanese, and the Kamtschatkans. "Calmucæ proprii," says Pallas, "Mongoli, Buriates, Kirgufes, Solones Orientales, Tungusi Dauriæ, et Sineses septentrionales sibi invicem simillimi sunt." (Voy. en Sibérie.) "Les Samoyèdes de l'Ob ressemblent beaucoup aux Tungooses. Ils ont le visage plat, rond et large. Ils ont peu de barbe, et les cheveux noirs et rudes." "On trouve les restes de cette nation dans la partie orientale de la Sibérie près de l'Enifféi. Les Koibals, les Kamaches, les Abotors, les Soiets, les Karagasses ont la même figure que les Samoiedes, et parlent tous leur langue." (Ibid.) "The Kamtschadales and Mungals (Mongols) are swarthy, have black hair, little beard, broad faces, nose short and flat, eyes small and sunk, the belly protuberant, and the legs small. The language of the Kamtschadales resembles the Mungal Chinese." Steller's Voyage to Kamtschatka.

"The Japanese in general, particularly the common people of Nipon, are ugly, short, strong, thick-legged, tawny, with flattish noses and thick eye-lids, though the eye stands not so deep in the forehead as in the Chinese. The noble families are more majestic in shape and countenance, and more like Europeans." Kæmpfer.

"The Mantchoo Tatars are scarcely distinguishable from the Chinese by external appearances: the Chinese are somewhat taller, but their features almost exactly resemble. The natural colour, both of Chinese and Tatars, seems to be that tint between a fair and a dark complexion, which we distinguish by the word brunet or brunette; and the shades of this complexion are deeper or lighter, according as they have been more or less exposed to the influence of climate. The women of the lower class, who labour in the fields, or who dwell in vessels, are almost invariably coarse, ill-featured, and of a deep brown complexion, like that of the Hottentots. We saw women in China, though very few, who might pass for beauties even in Europe. A small black or dark brown eye, a short rounded nose, generally a little flattened, lips considerably thicker than in Europeans, and black hair, are universal." (Barrow's China.) "Besides the general similarity of the tribes occupying such vast and distant regions, it is curious to observe that the Samoiedes, Kamtschatkans, and others towards the north, have a much darker skin than the Calmucks, Mantchoos, and Chinese in warmer countries." Prichard's Disputatio, p. 93—99.

"India is inhabited by a mixed race, made up of the aborigines, and of others whom the pursuits of war and conquest have at various times brought there. The religion of Brahma seems to have been conveyed there from the north;

north; and at later periods vast numbers of the Mongols have entered and conquered the country. These mixtures have effaced the peculiar characters of the original inhabitants, which we must, therefore, seek for in the islands, protected by their situation from such visits. The islands of the Indian sea, as well as those of the Pacific, contain two races of men, differing in many respects. One of these approaches, and in some instances equals, the blackness of the Negro: the hair is curled and woolly, the body slender, the stature short, the disposition barbarous and cruel. The other is more like the Indians of the continent, has a fairer skin, larger limbs and stature, better proportions, and exhibits some marks of humanity and civilization. According to Forster, the former, who are aborigines, have occupied the middle and mountainous parts of many islands, leaving the coasts and plains to the more recent colonists. They occupy the highest parts of the Moluccas, the Philippines, Formosa, and Borneo; all New Guinea, New Britain, Hibernia and Caledonia, Tanna, Mallicollo, New Holland, and Van Diemen's land. The more recent nation occupies Sumatra, and the other islands of the Indian sea, Otaheite, and the Society islands, the Friendly islands, Marquesas, Ladrones, Marian and Caroline islands, New Zealand, Sandwich and Easter islands. The language of all the latter resembles the Malay, and there can be no doubt that they arise from that race, and have spread by their ships over these distant spots. The black people are every where barbarous, and, according to Forster, have languages not agreeing with each other. In neither can we perceive any traces of the influence of climate. The latter race, scattered in various parts of the vast island of New Holland, which has such variety of temperature, every where retains its black colour, although the climate at the English settlement is not much like that of England; and in Van Diemen's land, extending to 45° S. lat. (it is well understood that the cold is much more severe in the southern hemisphere, at an equal distance from the equator, than in the northern) they are of a deep black, and have curled hair like the negroes.

"We may make the same remarks concerning the Malay race. The Sumatrans under a vertical sun are the fairest people of the Indian islands: and Marsden relates, that they sometimes approach the whiteness of Europeans. The inhabitants of Otaheite are very fair: yellow hair is not unfrequently seen amongst them; while those of New Zealand, twice as distant from the equator, are much darker." (Ibid. 85—89.) It is sufficiently obvious that in Asia, where we have countries with every variety of situation and temperature, at every distance from the equator, with every diversity of elevation, hills, vallies, plains, islands and continents, we can trace no effect of climate on the colour, or on any other character of the human race.

African Races.—On the hypothesis, which assigns the varieties of mankind to the operation of climate as their cause, we should expect to find in Africa all tribes under the equator of the most intensely black colour; the tinge should become lighter and lighter as we proceed thence towards the south, and the complexion ought to be white when we arrive at regions which enjoy an European climate. This, however, is by no means the case. The Abyssinians, on the east, with dark olive colour and long hair, are placed near the equator, and surrounded by negroes. In the same part also, the Gallas, a great and barbarous nation, having, according to Bruce, long black hair, and white skin verging to brown, occupy extensive regions under the equator itself. On the other hand, as we proceed from the equator towards the south, through tribes of negroes, we find the black co-

lour continued with undiminished intensity. It is known in the West Indies, that the Congo negroes in the blackness of their skin and woolly hair equal any race of Africans. Paterfon assures us that the Caffres, within a few degrees of the Cape of Good Hope, where the climate is so far from being intolerably hot, that the corn is often hurt by the winter frost, are of the deepest colour; and the same fact is familiarly known of the surrounding tribes.

The island of Madagascar, which is cooled by the mild breezes of the Indian ocean, and ought, therefore, to contain a white race, has two kinds of natives: one of olive colour with dark hair; the other true negroes.

The Hottentots, at one or two degrees from the deep black Caffres, are of a brownish-yellow colour: this distance can hardly account for the difference. The observations of Barrow on the countenance and form of this race, render it probable that they owe their origin in part to the Chinese, which circumstance will enable us to explain their colour very easily. He says that the eye-lids are joined towards the nose, by a rounded sweep without any angle: that the limbs and joints are small both in the Hottentots and the Chinese: that the voice and mode of speaking are nearly the same in both: that a broad nose, slanting eyes depressed towards the nose, and other features, are common to both. The hair has a middle character between that of the Negro and Chinese; it is such, in short, as the intermixture of the two races may be expected to produce.

When we consider how large an extent of Africa is occupied by the black woolly-haired negroes, and that these regions vary in their latitude, their elevation, and every other point; that they include sandy deserts, coasts, rivers, hills, vallies, and very great varieties of climate, the conclusion that these adventitious circumstances do not influence the colour or other properties of the race is irresistible.

American Races.—It only remains for us to examine the continent of America, which, as it stretches uninterruptedly from the neighbourhood of the north pole to 55° S. lat. and includes regions diversified in every possible way, affords the most ample opportunity for the development of all the changes that such causes can produce; and to examine whether the facts ascertained concerning its inhabitants are more favourable to the hypothesis of climate than what we have observed in the other three divisions of the world.

The reports of travellers are unanimous concerning the identity of character in the whole American race: copper-coloured skin, long and straight black hair, and a certain cast of features, are said to belong to all the inhabitants of this extensive continent. How remarkable this agreement is may be collected from the statement sometimes made, that a person who has seen one may consider that he has seen all; which, however, in its full extent, must be conceived as an exaggerated or partial view. The Esquimaux are not included in this account: their colour is more of the olive cast; in which, as well as in other points, they betray their Asiatic origin.

Herrera, Ulloa, and others who have visited the American continent, affirm, that all the native tribes, both of the northern and southern divisions, are of the same colour. We may cite the testimonies of Stedman, Hearn and Mackenzie, Wallis and Cook, who ascribe the copper colour respectively to the natives near Surinam, those in the regions farthest north, and to the Patagonians and inhabitants of Terra del Fuego. Humboldt, whose extensive opportunities of observation and philosophic spirit give great weight to his statements, confirms this representation in the most ample manner.

"The Indians of New Spain bear a general resemblance

to those who inhabit Canada, Florida, Peru, and Brazil. They have the same swarthy and copper colour, flat and smooth hair, small beard, squat body, long eye, with the corner directed upwards towards the temples, prominent cheek-bones, thick lips, and an expression of gentleness in the mouth, strongly contrasted with a gloomy and severe look. The American race, after the Hyperborean race, is the least numerous; but it occupies the greatest space in the globe. Over a million and a half of square leagues, from the Terra del Fuego islands to the river St. Lawrence and Beering's straits, we are struck at the first glance with the general resemblance in the features of the inhabitants. We think we perceive that they all descend from the same stock, notwithstanding the enormous diversity of language that separates them from each other. However, when we reflect more seriously on this family likeness, after living longer among the indigenous Americans, we discover that celebrated travellers, who could only observe a few individuals on the coasts, have singularly exaggerated the analogy of form among the Americans."—"The uniformity of the red coppery complexion, and dark, coarse, and glossy hair, conceals for a long time the diversity of individual features." "The Indians of New Spain have a more swarthy complexion than the inhabitants of the warmest climates of South America. This fact is so much the more remarkable, as in the race of Caucasus, which may also be called the European Arab race, the people of the south have not so fair a skin as those of the north. Though many of the Asiatic nations, who inundated Europe in the sixth century, had a very dark complexion, it appears that the shades of colour observable among the white race, are less owing to their origin or mixture than to the local influence of the climate. This influence appears to have almost no effect on the Americans and Negroes. These races, in which there is abundant deposition of carburetted hydrogen in the corpus mucosum or reticulatum of Malpighi, resist in a singular manner the impressions of the ambient air. The Negroes of the mountains of Upper Guinea are not less black than those who live upon the coast. There are, no doubt, tribes of a colour by no means deep among the Indians of the new continent, whose complexion approaches to that of the Arabs or Moors. We found the people of the Rio Negro swarther than those of the lower Orinoco, and yet the banks of the first of these rivers enjoy a much cooler climate than the more northern regions. In the forests of Guinea, especially near the sources of the Orinoco, are several tribes of a whitish complexion, the Guaiacas, Gunjaribs, and Arigues, of whom several robust individuals, exhibiting no symptom of the asthenical malady which characterizes Albinos, have the appearance of true Mestizos. Yet these tribes have never mingled with Europeans, and are surrounded by other tribes of a dark brown hue. The Indians in the torrid zone, who inhabit the most elevated plains of the Cordillera of the Andes, and those who, under the 45th of S. lat. live by fishing among the islands of the Archipelago of Chonos, have as coppery a complexion as those who under a burning climate cultivate bananas in the narrowest and deepest vallies of the equinoctial region. We must add, that the Indians of the mountains are clothed, and were so long before the conquest, while the aborigines, who wander over the plains, go quite naked, and are consequently always exposed to the perpendicular rays of the sun. I could never observe that in the same individual those parts of the body which were covered were less dark than those in contact with a warm and humid air. We every where perceive that the colour of the American depends very little on the local position in which we see

him." Political Essay on the Kingdom of New Spain, vol. i. p. 140—145.

How does it happen, that the same sun, which makes the African black, tinges the American of a copper colour? and that the dark hue, which might possibly be produced by heat in the equatorial regions, should be found also in the cold and inhospitable tracts of Terra del Fuego, and the most northern part of the continent? The absence of white races can surely not be ascribed to the want of sufficiently cold climates. Bougainville found the thermometer, in the middle of summer, $54\frac{1}{2}^{\circ}$ in lat. 52° ; and Messrs. Banks and Solander, and their attendants, had nearly perished all together from the cold, in an excursion in Terra del Fuego, in the middle of the summer. Two of the servants were actually lost.

Differences in the same Regions.—A very cursory survey of the globe will shew us that the same regions have been occupied by men of different races, without any interchange of characters, in many instances, for several centuries. The Moors and Negroes are found together in Africa; Europeans, Negroes, and Americans in North and South America; Celts, Germans, and Slavons in Europe, and even in the same kingdoms of Europe, &c. &c. The distinctions of these different races, except where they have been confuted by intermarriages, is just as easy now as it has been in any time, of which we have authentic records.

Permanence of the original Character, when the Climate is changed.—The permanency of the characters of any race when it has changed its original situation for a very different one, when it has passed into other climes, adopted new manners, and been exposed to the action of these causes for several generations, affords the most indisputable proof that these characteristics are not the offspring of such adventitious circumstances. From the numerous examples, in every race, which a slight knowledge of history will furnish, we shall select a few of the most striking.

The establishments of the Europeans in Asia and America have now subsisted about three centuries. Vasquez de Gama landed at Calicut in 1498; and the Portuguese empire in India was founded in the beginning of the following century. Brazil was discovered and taken possession of by the same nation, under Alvarès Cabral in 1500. Towards the end of the fifteenth, and the beginning of the sixteenth century, Columbus, Cortez, and Pizarro subjugated for the Spaniards the West Indian islands, with the empires of Mexico and Peru. Sir Walter Raleigh planted an English colony in Virginia in 1584; and the French settlement of Canada has a rather later date. The colonists have, in no instance, approached to the natives of these countries; and their descendants, where the blood has been kept pure, have, at this time, the same characters as native Europeans. In the hotter situations indeed, as in the warmer countries of Europe, the skin is swarthy; but the children, at the time of birth, and women who are never exposed much to the sun's rays, have all their native whiteness. This observation admits of no exception: in the tint of the skin, the colour and other qualities of the hair, the features, the form of the cranium, the proportions and figure of the body, the European colonists retain all their original characters. The sanguine constitution, with its blue eyes, yellow hair, and fair skin, which is so remarkably different from that of the natives, is nevertheless transmitted without the least alteration from generation to generation.

Negroes have been introduced into the new world for nearly an equal length of time: in the West Indian islands, in the United States, in the various parts of Spanish America, they live under new climates, and have adopted

new habits. Yet they have still woolly hair, black skins, flat nose, thick lips, and all the other characters of their race.

The Vandals passed from Spain into Africa about the middle of the fifth century: their descendants may be still traced, according to Shaw, in the mountains of Atlas, by their white and ruddy complexion, and yellow hair. The change, produced by climate, must be infinitely small, since it is not yet perceptible after a lapse of thirteen centuries.

The inhabitants of Persia, of Turkey, of Arabia, of Egypt, and of all Barbary, may be regarded as the same race of people, who, in the time of Mahomet and his successors, extended their dominions by invading immense territories. In all these situations the skin retains its native fairness, unless the tint be changed by exposure to the sun: and the children are invariably fair. "Il n'y a femme de laboureur ou de paysan en Asie (Asia Minor) qui n'a le teint frais comme une rose, la peau delicate et blanche, si polie et si bien tendue, qu'il semble toucher du velours." (Obl. de Pierre Belon, p. 199.) The Arabians are scorched by the heat of the sun, for most of them are either covered with a tattered shirt, or go entirely naked: La Boullaye informs us, that the Arabian women of the desert are born fair, but that their complexions are spoiled by being continually exposed to the sun. (Voyages de la Boullaye le Gouz, p. 318.) Another traveller remarks that the Arabian princesses and ladies, whom he was permitted to see, were extremely handsome, beautiful, and fair, because they are always covered from the rays of the sun; but that the common women are very much blackened by the sun. Voyage fait par Ordre du Roi dans la Palestine, p. 260.

The Moors, who have lived in Africa since the seventh century, have not degenerated in their physical constitution from their Arabian progenitors: the sun exerts its full influence on their skin, but their children are just as white as those born in Europe. They are by no means confined to the northern coast, but have penetrated, as the prevalence of the Mahometan religion attests, deeply into the interior: here they dwell in countries, of which the woolly Negro is the native, but have not acquired, in six centuries of exposure to the same causes, any of his characters. The intelligent and accurate Shaw informs us that most of the Moorish women would be reckoned handsome even in Europe; that the skin of their children is exceedingly fair and delicate, and though the boys, by being exposed to the sun, soon grow swarthy, yet the girls, who keep more within doors, preserve their beauty till the age of thirty, when they commonly give over childbearing. "Les Maures," says Poiret, "ne sont pas naturellement noirs, malgré le proverbe, et comme le pensent plusieurs écrivains; mais ils naissent blancs, et restent blancs toute leur vie, quand leurs travaux ne les exposent pas aux ardeurs du soleil. Dans les villes les femmes ont une blancheur si éclatante, qu'elles eclipseroient la plupart de nos Européennes; mais les Mauresques montagnardes, sans cesse brûlées par le soleil et presque toujours à moitié nues, deviennent, même dès l'enfance, d'une couleur brune qui approche beaucoup de celle de la suite." (Voy. en Barbarie, tom. i. p. 31.) The testimony of Bruce is to the same effect.

That the swarthiness of the Southern Europeans is merely the effect of the sun's action on the individual, whose children are born perfectly white, and continue so unless exposed to the operation of the climate, might be easily proved of the Spaniards and Portuguese, the Greeks, Turks, &c. but the fact is too well known to render this necessary.

The Jews exhibit one of the most striking instances of

peculiar national formation, unaltered by the most various changes. They have been scattered, for ages, over the face of the whole earth; but their peculiar religious opinions and practices have kept the race uncommonly pure; accordingly their colour and their characteristic features are still the same under every diversity of climate and situation.

We consider it as sufficiently proved that native differences in general, and particularly that of colour, do not depend on extraneous causes: we have an observation or two to make on some other points. That the curled hair of the African is not produced by heat appears from its being found, in many situations, not remarkable for high temperature, as the Moluccas, New Guinea, Mallicollo, Borneo, New Holland, and even in the cold region of Van Diemen's land; as well as from the hot regions of Asia and America being inhabited by a long-haired race. The differences in stature, again, have been very confidently ascribed to adventitious causes. Temperate climate, pure air, copious food, &c. have been thought favourable to the full development of the human frame; while extreme cold, bad and unwholesome food, noxious air, and similar causes, have been thought capable of reducing the dimensions of the body below the ordinary standard. That these causes may have some effect on individuals we do not deny, although we believe that it is very slight: but the numerous examples of large people in cold countries, and diminutive men in warm climates, induce us to deny altogether its operation on the race. The tall and large-limbed Patagonians, the Tschutski, and the North Americans inhabit cold situations; the Monguls, who are small in stature, live in warm countries.

The foregoing facts and arguments warrant us, as we conceive, in drawing (with Dr. Prichard, Diff. p. 119.), the following conclusions.

1. That climate, manners, and other physical and moral causes, have some power in modifying the natural constitution of man, as well as of animals.
2. That the influence of such causes is confined to one generation; and that no alteration produced in this way, or brought about by art or chance, is transmitted to the offspring.
3. That all the diversities of mankind are examples of a propensity to the formation of natural varieties, common to all animals under certain circumstances, follow the same laws, and are to be ascribed to the same cause.
4. Therefore, that the hypothesis of different species having been originally formed, is unnecessary for the explanation of the phenomenon.

Divisions of Mankind. Arrangement of Man as an Object of Natural History.—Order, Bimanus. Genus, Homo. Erectus, bimanus, inermis, rationalis, loquens: mento prominulo: dentes incisores supra & infra quatuor: dentes omnés æqualiter approximati; lanarii reliquis longitudine æquales; incisores inferiores erecti. See Blumenbach, Handbuch der Naturgeschichte. Species, H. sapiens.

Varieties.—As we have shewn, on the one hand, that there is no circumstance of difference between the varieties of the human race, which does not appear in a still greater degree among animals chiefly of the domesticated kinds, arising from the ordinary sources of degeneration: so there is no point, whether of colour, countenance, or stature, which does not pass by imperceptible gradations into the opposite character, rendering all these distinctions merely relative, and reducing them to differences in degree. Hence it is obvious, that any division of the varieties of the human race must be in a great measure arbitrary.

The single species then, which the genus Homo contains, is divided by Blumenbach into the five following varieties;

rieties; 1. Caucasian; 2. Mongolian; 3. Æthiopian; 4. American; 5. Malay. The Caucasian, for reasons which will afterwards be mentioned, is regarded as the primitive stock. This deviates into two extremes most remote and different from each other; viz. the Mongolian on one side, and the Æthiopian on the other. The two remaining varieties hold the middle places between the Caucasian and the two extremes: that is, the American comes in between the Caucasian and Mongolian; and the Malay between the Caucasian and Æthiopian.

These five varieties may, on the whole, be defined by the following marks and descriptions. But it is necessary to observe, in the first place, that on account of the multifarious diversity and gradations of characters, one or two are not sufficient for determining the race, consequently that an union of several is required; and, secondly, that even this combination of characters is subject to numerous exceptions in each variety. The union of the different races by inter-marriages, and the changes of situation for the purposes of war and conquest, that lead to these, account for a great deal of this uncertainty. On the whole, however, the following will be found a tolerably clear and correct view of the matter.

1. *Caucasian Variety*.—White skin, inclining to brown, red cheeks, hair black and of the various lighter colours, head of a somewhat globular form; oval and straight face, with features moderately separate from each other, expanded forehead, narrow and rather aquiline nose, and small mouth: front teeth of both jaws perpendicular; lips, particularly the lower, gently turned out; chin full and rounded. In short, that kind of countenance which accords with our notions of beauty.

It includes all the Europeans, except the Laplanders and the rest of the Finnish race; the Western Asiatics, as far as the river Ob, the Caspian sea, and the Ganges; that is, the proper Tatars, the Georgians, Circassians, Mingrelians, &c. the Persians, Arabians, Syrians, the Turks; the Northern Africans, as the people of the Barbary states; the Egyptians and Abyssinians.

The name of this variety is derived from mount Caucasus, because in its neighbourhood, and particularly towards the south, we meet with the most beautiful race of men in the world, viz. the Georgians. From the accounts of numerous travellers, who all agree on this subject, we select the remark of Chardin: "The blood of Georgia is the finest in the east, and I may say in the world. I have not observed a single ugly countenance in that country in either sex; but have seen numerous angelic ones. Nature has bestowed on the women graces and charms, which we see in no other place. It is impossible to look at them without loving them. More beautiful countenances, and finer figures, than those of the Georgian women, cannot even be imagined." *Voyage en Perse*, t. i. p. 171.

Many reasons induce us to believe, that the primitive form of the human race, was that which we have described as belonging to the Caucasian variety; and of which the Georgians, Turks, Greeks, and some Europeans, exhibit now the finest specimens. This race has the most beautifully formed cranium, (see CRANIUM, and *Anatomy of the Cranium*, Pl. 1. fig. 1.) from which, as from a middle and primitive configuration, the other forms descend by a most easy and simple gradation, on the one hand to the Mongolian, and on the other to the Æthiopian variety. The proportions of the body in general are the most beautiful in this race, and their minds are the most acute, so that nearly all the arts and sciences have been discovered by them. They occupy the middle regions of the globe, while the extre-

mities are filled by others. The most ancient, and most early civilized nations have belonged to this variety. To this form also, according to the observation of Blumenbach, there is a disposition to return in the other races; as may be observed in the South sea islands, and some parts of Africa; while this does not easily deviate into the dark coloured varieties.

If we admit the Caucasian to have been the primitive form of man; are we to suppose, that the eyes were blue, and the hair yellow or red, or that both were black? we can have little hesitation in adopting the latter opinion, since that formation belongs to all of this race except the Germans, which have occupied only the more distant regions. It forms, too, the middle colour of the human race, and appears often in scattered instances among the other varieties. Moreover, yellow or tawny breeds occur among animals, as in the rabbit and cat, by degeneration from the native colour.

In this Caucasian variety, Blumenbach and most others include the German race; but Dr. Prichard assigns it a separate place under the name of "constitutio Germanica aut sanguinea." The form and proportions of the cranium, face, and body in general, are the same as in the preceding; the features perhaps are rather less acute, and more rounded, and the eyes smaller. The whole stature and the limbs are rather larger. But the most prominent distinctions are in the very white skin, approaching to redness; in the yellow or red hair, and the blue eyes.

2. *Mongolian Variety*.—Olive colour; black, straight, strong, and thin hair, scarcely ever curled; head of a square form; broad and flattened face, with the features running together; the glabella (interval between the eye-brows) flat and very broad; nose small and flat; rounded cheeks projecting externally; narrow and linear aperture of the eyelids; eyes placed very obliquely; slight projection of the chin; large ears, thick lips. The stature, particularly in the countries near the North pole, is below that of the Europeans.

This includes the rest of the Asiatics (excepting the Malays); the Finnish races of the colder parts of Europe, as the Laplanders, &c.; and the tribes of Esquimaux, extending over the northern parts of America, from Beering's strait to the extremity of Greenland.

The Mongolians, widely scattered over the continent of Asia, have generally, but erroneously, been included with some of very different origin and formation, under the name of Tartars; whereas the last-mentioned tribes, properly so called, belong to the first division of the human race. The Calmucks, and other Mongolian nations, which overran the Saracen empire, under Zenghis Khan, about the middle of the thirteenth century, and had entered Europe, are described in the "Historia Major" of Matthew Paris under the name of Tartars, whereas that name (or, as it should be spelled, Tatars) properly belongs to the western Asiatics, who had been vanquished by the Monguls. The error, however, arising from this source, has been propagated down to the present day, so that in the works of the most approved naturalists, as Buffon and Erxleben, we find the characters of the Mongolian race ascribed to what they call the Tartars.

The Tatars indeed are connected by the Kirguses, and neighbouring tribes, to the Monguls, in the same way as the latter are joined by the inhabitants of Thibet to the Indians; by the Esquimaux, to the Americans; and by the Philippine islanders, with the Malays.

3. *Æthiopian Variety*.—Black skin and eyes; black and woolly hair; head narrow, and compressed laterally; arched forehead; cheek-bones standing forwards; prominent eyes; thick

thick nose, confused with the extended jaw; alveolar arch narrow, and elongated anteriorly; the upper front teeth projecting obliquely; the lips, and particularly the upper one, thick; the chin receding; knees turned in in many instances. The remaining Africans, besides those classed in the first variety, belong to this.

The striking peculiarities of this variety, and particularly the very great difference between its colour and our own, have led many persons to adopt the opinion of Voltaire, who had not a sufficient knowledge of physiology and natural history to determine the question, that the Africans belong to a distinct species. We have shewn, in the preceding divisions of this article, that there is no one character so peculiar and common to the Africans, but that it is found frequently in the other varieties, and that negroes often want it; also, that the characters of this variety run by insensible gradations into those of the neighbouring races, as will be immediately perceived by comparing together different tribes of this race, as the Foulahs, Wulufs, and Mandingoes, and carefully noting how in these gradational differences they approach to the Moors, New Hollanders, &c.

Again, great stress has been laid on the fact, that the negroes resemble more nearly than the Europeans, the monkey tribe; the fear of being drawn into the family, even as distant relations, has we believe induced many to place our black brethren in a distinct species; while others have brought forwards this approximation to the simiæ, with the view of degrading the African below the standard of the human species, and thereby palliating the cruel hardships under which he groans in the islands and continent of the new world.

It is undoubtedly true, that in many of the points, wherein the Æthiopian differs from the Caucasian variety, it comes nearer to the monkeys; viz. in the greater size of the bones of the face, compared to those of the cranium; in the protuberance of the alveoli and teeth, recession of the chin, form of the ossa nasi, position of the foramen magnum occipitale, outline of the union of the head and trunk, relative length of the humerus and ulna, &c. This resemblance is most unequivocally admitted by Soemmerring; über die körperl. verschied. p. 19, and § 69. It appears to us, that this fact is not very important; if there are varieties of bodily formation among mankind, some one of these must approach nearer to the organization of the monkey than the others; but does this prove, that the variety in which the conformity occurs, is less man than the others? The solidungular variety of the common pig is more like the horse than other swine; do we hence infer, that the nature of this animal in general is less porcine, or more like that of the horse, than that of other pigs? The points in which the Negro differs from the European, are trivial and few, and do not touch upon those important characters which separate man in general from the animal world; the erect attitude, the two hands, the slow development of the body, the use of reason, and consequently perfectibility, are attributes common to both.

That very little importance can be attached to the general observation of the resemblance of the negro and monkey founded on external appearance, may be clearly inferred from this fact, that the same remark has been made, even by intelligent travellers, of particular people in the other varieties. Regnard concludes his description of the Laplanders with these words: "voilà la description de ce petit animal qu'on appelle Lapon, et l'on peut dire qu'il n'y'en a point, après le singe, qui approche plus de l'homme. (Œuvres, t. i. p. 71.) An Esquimaux, who was brought to

London by Cartwright, when he first saw a monkey, asked "Is that an Esquimaux?" His companion adds, "I must confess, that both the colour and contour of the countenance had considerable resemblance to the people of their nation." Nic. del Techo calls the Caaiguas of South America, "tam simiis similes, quam hominibus," Relat. de Caaig. gente, p. 34; and J. R. Forster, in the observations on his journey round the world, asserts "that the inhabitants of the island Mallicollo, of all the people whom I have seen, have the nearest relationship to the monkeys."

4 *American Variety*.—Red colour; black, straight, strong, and thin hair; short forehead; deep eyes; nose somewhat flattened, but prominent; a broad, but not flattened face, with the cheeks standing out, and the different features projecting distinctly and separately; the forehead and vertex often deformed by art. This variety includes all the Americans, with the exception of the Esquimaux.

Several idle tales have been propagated, concerning the distinguishing characters of this race. Some have denied the existence of a beard in the male, and that of the menstrual discharge in the female; and others have ascribed an uniform colour and countenance to all the inhabitants of this vast continent. The concurring testimonies of all accurate modern travellers, prove clearly that the Americans have naturally beards; and that the report of their deficiency has arisen from their practice of eradicating it. See the general observations in this article on the beard.

The fabulous report of the American women not being subject to the menstrual discharge, seems to have arisen from the European travellers, who saw numerous females almost naked, having observed nothing of it. Two circumstances will account for this, according to Blumenbach: "partim nempe quod apud istas Americæ gentes feminae quamdiu menstruatæ sint, felici præjudicio pro venenatis quasi habeantur, inque remotioribus tuguriolis e hominum conspectu remotæ tamdiu benefico ipsis otio fruuntur; partim vero etiam laudatam ipsarum corporis munditiam et modestam crurum commissuram eo conferre ut nulla catameniorum vestigia in oculos incurrant, annotatum est." De Variet. p. 313.

The redness of the skin is not so constant, but that it varies in many instances towards a brown, and approaches likewise in some temperate situations to the white colour. Cook states, that the natives about Nootka Sound are little inferior in fairness to Europeans; and Bouguer makes the same observation of the Peruvians on the Andes. It is also fully ascertained at present, that the Americans possess the same varieties of feature which are observed in the other races.

5 *Malay Variety*.—Brown colour; hair black, soft, curled, and abundant; head moderately narrow, and forehead slightly arched; nose full and broad towards the apex; large mouth; upper jaw rather prominent; the features, when viewed in profile, projecting and distinct. The inhabitants of the peninsula of Malacca, of the South sea, Ladrones, Philippine, Molucca, and Sunda islands, are arranged under this division.

As the Americans in their national characters, hold the middle place between that middle variety of the human race, which we have called the Caucasian, and one of the extremes, viz. the Mongolian; so the Malay forms the connecting link between the Caucasian and the Ethiopian. The name of Malay is given to it, because most of the tribes which it includes, as those which inhabit the Indian islands near Malacca, the Sandwich, Society, and Friendly islands, also those of Madagascar, and thence to Easter island, use the Malay language. See Hawkesworth's collection, v. iii.

p. 373; Cook's Voyage to the northern Hemisphere, v. iii. p. 520; Marfden, in *Archæologia*, v. vi. p. 154.

Arrangements of other Naturalists.—The great number and diversity of the objects, the contradictory, imperfect, and confused accounts which we possess of many of them, render all classifications very arbitrary; hence very different divisions have been adopted by different systematic writers.

Of Linnæus.—This naturalist places the genus HOMO in his order Primates, and gives him the company of the monkies, lemurs, and bats; the characters of the order are, "dentes primores incisores, superiores quatuor, paralleli: mamma pectorales binæ." He admits three species:

I. HOMO SAPIENS; Diurnus, varians cultura, loco. Corpus erectum nudum, pilis raris remotissimis asperum, subsexpedale.

Varieties. *Ferus*; Tetrapus, mutus, hirsutus.

Americanus; Rufus, cholericus, rectus.

Pilis nigris, rectis, crassis; naribus patulis; facie ephelítica; mento subimberbi.

Pertinax, contentus, liber.

Pingit se lineis dædaleis rubris.

Regitur consuetudine.

Europæus; Albus, sanguineus, torosus.

Pilis flavescens prolisus. Oculis cæruleis.

Levis, argutus, inventor.

Tegitur vestimentis arctis.

Regitur ritibus.

Asiaticus; Luridus, melancholicus, rigidus.

Pilis nigricantibus. Oculis fuscis.

Severus, fastuosus, avarus.

Tegitur indumentis laxis.

Regitur opinionibus.

Afer; Niger, phlegmaticus, laxus.

Pilis atris, contortuplicatis. Cute holosericea,

nafo simo. Labiis tumidis. Feminis sinus

pudoris; mamma lactantes prolisæ.

Vafer, segnis, negligens.

Ungit se pingui.

Regitur arbitrio.

Monstrosus; Solo et arte variat:

Alpini parvi, agiles, timidi.

Patagonici, magni, segnes.

Monorchides, ut minus fertiles; Hottentotti.

Junceæ puellæ abdomine attenuata; Europeæ.

Macrocephali capite conico: Chineses.

Plagiocephali capite antice compresso: Canadenses.

II. H. TROGLODYTES; Nocturnus: habitat in Æthiopiæ conterminis, in Javæ, Amboinæ, Ternatæ speluncis, in monte Ophir Malaccæ.

This seems to be a medley, composed of the characters of the leucæthiopes, and ourang-outangs.

III. HOMO LAR; brachiis longitudine corporis.

This is the gibbon, or long-armed monkey.

Of Buffon.—1. Lapponic or polar: 2. Tataric (Mongolian): 3. Southern Asiatic: 4. European: 5. Æthiopian: 6. American.

Of Erxleben (Syst. Regn. Anim. Mammalia).

HOMO; Dentes primores incisores, supra et infra quatuor: Ianarii conici, longitudine æquales approximati. Manus in palmis, non in plantis. Mammæ pectorales binæ. Cauda nulla.

Var. 1. *Lappo*; Parvus, torosus, albus, macrocephalus, facie plana lata, maxilla inferiore prominula acuminata vix barbata, oculis parvis profundis nigro fuscis, nafo parvo ob-

tuso, buccis inflatis, ore magno, labiis crassis, auriculis magnis, pilis rectis nigris crassis, brachiis longioribus, manibus plantisque minoribus.

Habitat in borealibus Europa, Asia, America.

2. *Tatarus* (Mongolian): Mediocris olivaceus, facie plana lataque, fronte rugosa, oculis parvis profundis nigris, superciliis largis, nafo brevi crasso, labiis tumidis, mento prominente acuminato, barba rariore, dentibus longioribus interstitiis majoribus, pilis nigris crassioribus, femoribus crassis, cruribus brevioribus.

Ab Imao versus circum arcticum in Asia.

3. *Asiaticus*; Mediocris, luridus, rigidus, pilis nigricantibus, oculis parvis nigris, nafo depresso, labiis crassis, dentibus antrorsum versis.

Trans Gangem.

4. *Europæus*; Mediocris albus torosus, pilis flavescens prolisus, oculis cæruleis vel fuscis, labiis tenuioribus.

5. *Afer*; Magnus niger, cute holosericea ex reticulo mucofo Malpighiano crassiore nigroque, pilis atris, contortuplicatis, oculis nigris viridibusve, nafo simo, labiis tumidis, ventre inflato, manibus lactantibus prolisus.

Præcipue in Africa occidentali.

6. *Americanus*: Mediocris rufus, pilis nigris rectis crassis, facie ephelítica, fronte parvo, oculis nigris, nafo aquilino, naribus patulis, mento subimberbi.

Meiners adopts two chief divisions (haupt-stämme), the handsome and the ugly (schöne and hässliche); of which the former is white, the latter dark-coloured (dunkel farbige). The handsome division includes the Celtic, Slavonic, and Oriental people: the latter are the Armenians, Syrians, Arabians, Ægyptians, and others in the north-west of Africa, the Georgians, Circassians, Persians, the inhabitants of Hindoostan, Bucharia, and the neighbouring parts, and a large part of Siberia; under the ugly division come all the rest of mankind. Grundriss, chap. ii.

Of J. R. Forster.—1. Europeans, Asiatics on the west of the Ob, the Caspian, and the Ganges, Africans of Egypt, Nubia, Ethiopia, Cyrene, Tripoli, Tunis, Algiers, Fez, Morocco, and all the country as far as the river Sahara (Senegal?), in short the Caucasian of Blumenbach.

White, yellowish-brown, or even blackish colour; long face with well-formed nose and lips; yellowish-white, reddish-brown, or black hair, which is long and particularly curled in locks.

2. All the Asiatics beyond the Ob, the Caspian and the Ganges; all the Americans from Unalaska and Cook's river northwards to the northern icy ocean, and particularly Labrador and Greenland; all the inhabitants of the coasts in the Molucca, Philippine, western South sea islands, and New Zealand.

Yellowish-brown colour nearly universal; broad flattened faces with high cheek bones. Narrow opening of the eyelids, and internal angle of the eyes depressed towards the nose (that is situated lower down than the external). Hair universally black, long, and generally smooth and stiff.

3. Africans or Negroes, and the inhabitants of the internal parts of various Indian and South sea islands; and all New Holland.

Black with the under part of the face projecting: thick lips, broad flat noses, and woolly curled hair.

4. Americans, except those in the second variety. Copper red colour; nose thin, long and pointed; hair black, smooth, and stiff.

Of Dumeril.—The first family of his class of mammalia are the Bimanes, which have these characters: Mammiferes a membres

à membres séparés onguiculés; aux trois fortes de dents, et à pouces opposables aux mains seulement. He adopts the five varieties of Blumenbach, calling the first Caucasian or European-Arab; and adds a sixth, under the name of Hyperboréenne, which includes the men dwelling near the north pole in Europe, Asia, and America. *Zoologie Analytique*, p. 7.

The arrangements of some other authors may be found in Blumenbach de Varietate, sect. iv. § 83.; and in Ludwig's *Grundriss*, chap. vii.

It would be desirable to investigate the original abode of mankind, to ascertain the situations of the different races from the earliest authentic accounts, and to follow their migrations until we could trace them to the situations which they now occupy. To accomplish any thing satisfactory on this head, a very exact knowledge of the bodily characters of the races should be combined with exact historical information, and an acquaintance with languages, those living and unexceptionable testimonies of the affinities of people. On the former of these points, although it might at first appear that the facts are easily accessible, our data are still extremely imperfect; and history furnishes too feeble a light to guide us through the thick darkness that involves the origins of nations. We feel ourselves unable to bring forward any thing sufficiently clear and well-grounded to bear with much force on the principal points, which we have endeavoured to illustrate in this article. A short sketch of the subject is given in Dr. Prichard's *Dissertation*.

Principal Works on the Natural History of Man.—Buffon's natural history of man; his observations on mules, on the degeneration of animals, on wild and domestic animals, and indeed his natural history in general, contain a fund of most valuable information.

Blumenbach, de generis humani varietate nativa, ed. 3. Götting. 1795; his *Decades craniorum diversarum gentium illustratae*, 1—4; 4to. Gött. 1790—1800; his *Beiträge zur naturgeschichte*, Gött. 1790. 12mo.; his *Handbuch der naturgeschichte*, ed. 6. MAN of the Wood. See OURANG-OUTANG.

MAN, in *Geography*, an island situated in the Irish sea, at the distance of 30 nautical miles from St. Bees-head in Cumberland, and 27 from Strangford in Ireland. The latitude of the middle of this isle is $54^{\circ} 7'$ north, and its whole extent is about thirty miles in length, and ten in breadth. The whole is divided into two districts, which are subdivided into seventeen parishes. Concerning the etymology and derivation of its name, different opinions have been offered. Bishop Wilson supposes it to be derived from the Saxon word *mang*, signifying *among*, in allusion to its position, as surrounded by other territories, and this is justly regarded as a very probable conjecture, its present Manks appellation, Manning, still retaining the same meaning. Some other authors assert, that it plainly comes from Mona, a word which they imagine, but without sufficient authority, to have been used by Cæsar to denote this island. Ptolemy styles it *Monaeda*, or the more remote *Mona*, to distinguish it from *Anglesea*, the *Mona* of Tacitus. Pliny calls it *Menania*, Nennius *Eubonia*, and Orosius *Mevania*.

History.—According to tradition, the original inhabitants of Man were a colony from Britain. The primitive form of government established by them was, no doubt, that of the Druids, whose authority, in these distant times, was acknowledged by almost all the kingdoms of northern Europe. The institutions flowing from the Druidical system, seem to have been preserved here, even so late as the close of the fourth century, when the light of Christianity, under the direction of St. Patrick, penetrated the gloom of their umbrageous oaks, and by inducing new opinions, gave birth to new regulations in civil as well as in religious polity. At this period Boetius and other writers assert that the Isle of Man was celebrated as the "fountain of all pure learning, and the acknowledged residence of the muses." Nennius says that it was held by Buile, a Scot, in the reign of Arcadius and Honorius; but Sacheverel refers his government to a later era. St. Patrick appointed Germanus bishop and ruler of it, and after his death two other bishops succeeded him. St. Maughold, who had been captain of a band of robbers in Ireland, succeeded them, and from his period the bishops retained the government, till the coming of a king, called Orry, who continued for some years lord of Man. In the year 580 Brennus, descended from the blood-royal of Scotland, obtained the supreme authority. This prince having led an army to the assistance of his uncle, lost his life in an action with the enemy, on which event this island appears to have been annexed to the Scottish dominions. About 614 it was conquered by Edwin, king of Northumberland, from whose reign a blank occurs, even in tradition, till the arrival of a second Orry, in the tenth century. This monarch was

MAN, ISLE OF.

son of a king of Denmark and Norway, who, after reducing the Orcades and Hebrides, fixed his seat of government in the Isle of Man, where he reigned long and prosperously, as an independent king. In his reign, the house of Keys, which will be more particularly noticed hereafter, was established, as the constitutional parliament of the island. Gut-tred, the son of Oery, was distinguished as the Numa of his small kingdom, having devoted his whole attention to the civilization and welfare of his subjects. Reginald, who succeeded, was not less noted for his vices, which ultimately occasioned his assassination by the brothers of a lady whom he had dishonoured. Olave, the next prince of Man, unjustly suffered as a traitor, at the court of the king of Denmark, for having assumed the crown without his approbation. Olain, his brother, became his successor, and after an equitable reign, left his diadem to his son Allen, a tyrannical prince, who was poisoned. Macon next took possession of the sovereignty, but having refused to pay homage to the English crown, he was deposed by Edgar, but was afterwards reinstated in his former dignity with additional power. The English monarch is likewise said to have appointed him admiral of an immense fleet, (amounting, according to Matthew of Westminster, to 4800 sail, but this number is certainly incredible.) with which he sailed, twice a year, round the whole British islands, in order to protect their coasts from the piracies of the Danes and Normans. How long this great man continued to reign is uncertain, but towards the middle of the eleventh century we find Goddard, the son of Syrach, upon the throne, whose barbarous conduct rendered him extremely abhorrent to his subjects. Fingal, his son, succeeded, who, on the other hand, was greatly beloved for his mildness and generosity. In his reign, Godred Crovan, a Norwegian chief, arrived with a numerous fleet, and though twice defeated, at last obtained a decisive victory, the king and his principal officers being slain in the battle. This event occurred in the same year in which the conquest of England was effected by William of Normandy, and in consequence the whole island submitted to the superior fortune of Godred. During his government the monks greatly distinguished themselves in war. He first made a successful predatory incursion into Ireland, and afterwards subdued the Hebrides, and so effectually kept the Scots in awe by the power of his navy, that, to use the metaphorical language of the Russian monks, "they durst not, when building a ship or boat, drive more than three nails into it." Godred had three sons, the eldest of whom, named Lagman, succeeded to the throne. Harold, the second son, was long in rebellion against his brother, but being at last taken prisoner, had his eyes put out, and was otherwise mutilated.

Lagman afterwards repenting of this cruel conduct, was overwhelmed with sorrow, renounced his kingdom, and as an expiation of his guilt, made a pilgrimage to Jerusalem, where he died in 1089. Olave, his youngest brother, being yet a minor, the inhabitants of Man sent a deputation to Murchand O'Brien, king of Ireland, requesting him to send over some person of royal extraction to govern them till he should come of age. Accordingly this monarch nominated Donald Tade, who governed with such barbarity and extortion, that the indignant natives expelled him from the island within three years. The chiefs then elected Macmarus, but that event, notwithstanding the clemency of his rule, gave birth to a conspiracy against him, and in the battle which it occasioned, both he, and earl Oughter, the leader of the conspirators, fell. According to the Manks tradition, the northern men had nearly accomplished the victory, when the women of the south side flew with such resolution to the assistance of their husbands, as to turn the tide

of fortune in their favour. The Chronicon-Manniac, however, ascribes the victory to the inhabitants of the northern district. About this time, Magnus, king of Norway, having resigned his own throne on account of an absurd superstition, fitted out an army, with which he made himself master of the Orcades and Hebrides, as well as of the Isle of Man, where he landed the day succeeding the battle, and received the submission of the Manks without a contest. Here he established his seat of government, and after reigning six years, made a descent upon Ireland, where, having unwarily left his ship, he was surounded and slain, in the year 1102. During these transactions, Olave, the son of Godred, resided in great favour at the court of Henry I. of England. Upon the death of Magnus, however, the chiefs of Man immediately dispatched messengers to offer him the crown, which he readily accepted. Ascending the throne, to the great satisfaction of the people, he concluded treaties with all the neighbouring monarchs, and enjoyed profound peace for forty years of his reign. In 1142, however, during the absence of his son Godred, whom he had sent to Norway to do homage for the crown of Man, the three sons of his brother Harold landed on the island, and demanded one half of his kingdom. Olave, willing to pacify them, promised to submit the matter to his council, and appointed a place of meeting for that purpose, near Ramsey haven. The king, with his retinue, placed himself on one side, while his nephews, with their followers, seated themselves on the other. At this moment, Reginald, one of the princes, pretending to salute the king, suddenly raised his shining battle axe, and cut off the head of his aged and venerable uncle at one blow. A general slaughter of the nobility ensued, and the subjugation of the whole island, which the three brothers divided among themselves. In the same year they collected a fleet, and landed in Gal'oway, but were defeated with great slaughter. Just at this time Godred returned from Norway, and the inhabitants crowding to his standard, the usurpers deemed it advisable to submit to his authority, without hazarding a battle, whereupon Reginald was condemned to death, and the other two had their eyes put out. Godred, when he ascended the throne, was in the bloom of youth and manly intelligence, majestic in stature, magnanimous in his sentiments, and heroic in his actions. These qualities uniting with the recollection of his father's virtues, obtained him, not only the love of his own subjects, but the esteem of all the neighbouring nations. In the third year of his reign the fame of his merit induced the chief nobility of the province of Leinster to elect him their sovereign. Murchand, king of Ireland, opposed his accession, but being defeated, Godred seated himself on the throne to which the suffrages of the people had called him. His absence, however, excited considerable discontent in Man, which probably induced him, upon his return, to act somewhat in a despotical manner towards several of his nobility. One of them, named Thorfinus, a powerful and ferocious chief, fled to Summerled, thane of Argyle, in Scotland, who had married one of the daughters of Olave, and prevailed upon him to invade the western isles, then part of the dominions of Godred. These being reduced, he sailed with a large fleet to attempt the conquest of Man, but being met at sea by his brother in law, also at the head of a powerful armament, a dreadful battle ensued, which terminated in a peace, by which Godred retained Man, but ceded the other islands to Summerled. This event happened in 1156, but two years subsequent, the latter broke the treaty, and invaded Man with a fleet of 53 sail, defeated Godred, who sought refuge in Norway, and compelled the whole isle to submit to his sovereignty. This success so puffed up the ambition of Summerled, that he projected

MAN, ISLE OF.

jected the conquest of Scotland, and accordingly made a descent upon Renfrew with that intention, but was defeated in the first engagement, himself and his son being among the number of the slain. About the same time, Reginald, one of the illegitimate sons of Olave, having raised a party, invaded Man, and though opposed with great bravery by the Manks people, succeeded in defeating them by the treachery of one of their generals. His power, however, was but of short duration, for only four days after the commencement of his reign, Godred arrived from Norway with a large army, attacked and took prisoner the usurper, and was hailed by his subjects with the most cordial expressions of attachment. In the residue of this monarch's reign, mention is first made of the pope's influence in Man, his apostolic majesty having sent over from Ireland his legate, Vivian, who compelled the king to re-marry his queen, Phingola, according to the forms of the Romish church. Godred died in 1187, the latter years of his life being spent in perfect tranquillity, and left Olave, his only legitimate son, heir to his kingdom. Reginald, one of his natural sons, however, was appointed king during Olave's minority. This monarch, in 1192, fought a severe battle in the isles with Engus, the son of Sommerled, in which he was defeated with considerable loss. In 1203, he invaded Ireland, but was here unsuccessful also. In 1210, the Isle of Man was plundered by an English earl, named Fulco, during his absence on a visit to his more northern dominions. But notwithstanding these unfavourable circumstances, Reginald was enabled to retain the government, even after Olave, the rightful owner, had attained the years of maturity. But battles ensued, and the latter ultimately ascended the throne, and reigned till his death, which happened in 1237, when his son Harold was fourteen years of age. Having refused to appear at the court of the king of Norway, his territories were invaded by a Norwegian army, under Gofpatrick and Gillchrist, who converted the tributes of the country to the service of their own sovereign; but Harold, being at length induced to submit, failed over to Norway, and, performing the usual homage, was confirmed in the possession of all the islands which his predecessors had enjoyed. On his return home, he entered into treaties with the kings of England and Scotland. To the former he paid a visit, and received from him the honour of knighthood, and other distinguished marks of his royal favour. Soon after he failed from Norway to espouse the daughter of that monarch, offered to him in marriage by her father, but both he and his princess perished by shipwreck, when on their way back. His brother, Reginald, succeeded, who was slain only a few days after his accession to the throne by Yvar, a knight. Harold, the son of Godred Don, now assumed the title of king, but was soon obliged to surrender his usurped authority to Magnus, the son of Olave, who, as rightful heir, had obtained the sanction of the Norwegian monarch. This prince was the last sovereign of the Norwegian race in Mona. His death happened in 1268. At this period, the king of Norway finding himself unable to afford protection to his distant dominions, agreed to surrender the western islands to Alexander III., king of Scotland, from the dominions of whose ancestors they had been originally wrested by the Norwegian arms. This enterprising monarch soon after extended his authority over the island of Man also, and vested the government in thanes, or lieutenants. These behaving with great oppression towards the inhabitants, so exasperated the Manks, that they formed the resolution of exterminating the Scots, or perishing in the attempt. From this bloody purpose, however, they were restrained by the influence of their bishop, who proposed, in imitation of the warriors of

Rome and Alba, that the future fate of their country should be decided by a contest between select combatants. This proposal being eagerly embraced by both parties, thirty heroes were chosen on each side, and a vale was appointed as the scene of the conflict. The two nations covered the opposite mountains in anxious expectation, the one of confirming their conquests, and the other of regaining their former independence. The battle was long and heroically fought, but at length the Scots prevailed, though their thane, and five and twenty of their combatants, paid the forfeit of their lives for the glory of their country. After this period, no attempt seems to have been made by the Manks to regain their liberty, but their island now became the theatre of contests between Scotland and England. William de Montacute, a descendant of one of the Manks monarchs, having landed here with a body of English troops, forced the Scots to retire to their own country. In the reign of king Edward II. this island was bestowed on Gaveston, who was created earl of Cornwall. In 1340, it was recovered to the Scots by their heroic king, Robert Bruce, and continued in their possession till the earl of Salisbury, under the sanction of Edward III., wrested it again from their authority, and sold it to William Scroop, who was chamberlain to the king. On Henry's gaining possession of the throne, he granted the Isle of Man to the earl of Percy, who afterwards rebelling against his sovereign, had his estates forfeited by an act of attainder, but they were all afterwards restored, with exception of this island, which was bestowed on sir John Stanley and his successors for ever. In his reign, the laws of Man, which had hitherto been concealed in the bosoms of the deemsters, or judges, were first publicly promulgated, and committed to writing. For this purpose, the sovereign convened the entire body of the people at the Fynwald, where he himself attended, invested in all the insignia of royalty. All things being in readiness, the venerable deemsters rose, and, with an audible voice, alternately published to the assembly several laws, which, though more favourable to the monarch than to his subjects, were received with reiterated applause. From this period, the royalties and revenues of Man descended regularly, and without molestation, from ancestor to heir, till the time of William VI., earl of Derby, against whose title some objections were started and legally removed. To put the question beyond doubt, however, a new grant was obtained from James I., which afterwards received the sanction of parliament. It should be observed, that the fifth descendant of this line resigned the title of king, and assumed that of lord of the island, conceiving it to be more honourable to be esteemed a great baron than a petty and dependent monarch. In the time of the civil wars, Man held out for the king till near the close of that unhappy contest, when it was surrendered to the parliamentary forces. It was now granted to lord Fairfax, but upon the accession of Charles II. it was restored to the earl of Derby, son of him who had been beheaded at Bolton. In the same family it continued till the year 1735, when it became the inheritance of James, the second duke of Athol, as grandson of Sophia, youngest sister of that earl.

Before this period, the vast extent of the contraband trade carried on between this island and Great Britain, attracted the serious attention of the government, and an act was passed in 1726, authorising the lord of Man to resign his royalties for a pecuniary compensation; but no sale was effected till the 7th of March, 1765, when John, duke of Athol, resigned all his regal privileges and immunities for the sum of 70,000*l.* An annuity has since been granted by parliament, for the joint lives of himself and his duchess, as an additional

MAN, ISLE OF.

compensation for the loss he was supposed to have sustained by this transaction, which has, in no small degree, secured the revenues of the British islands.

The constitution and government may be partly inferred from the preceding narrative. About the fifth century the government became a despotic and feudal monarchy. In the tenth, the foundation was laid for a new dynasty called the House of Keys, whereby the inhabitants were allowed to choose sixteen representatives, who, with eight from the Isles, were to form the legislature. These representatives were called Taxiaxes, but neither the period of their election, nor the precise power with which they were invested, can now be ascertained. It is probable, however, that their privileges were very limited, and that, in reality, they were mere nominal advisers, all substantial power being vested in the person of the monarch. Indeed, no mention is made of any interference on the part of this assembly in public affairs till the thirteenth century, when the island was taken by Alexander, king of Scotland. At this period, however, they appear to have exercised the right of enquiring into the existing laws and petitioning for new ones, but they possessed no power of enactment. After the accession of the Stanley family the liberties of the people began to extend, and, in 1439, they obtained the exclusive privilege of electing the members of this assembly, who were increased to twenty-four in number for the Isle of Man alone. This dawn of liberty, however, was only of short duration, being destroyed by the House of Keys itself, which, upon the death of any of its members, proceeded to elect another in his stead, in direct opposition to the democratic principle upon which the institution was founded. Constituted notwithstanding as it was, this assembly proved no inconsiderable check upon the encroachments of the regal authority. In conjunction with the king, his council, and the deemsters, it possessed the entire legislative authority of the isle. These four estates were denominated the *Tynwald Court*. Since the purchase of the regalities by the British government, the power of this court has been considerably restricted, but it still retains the right of making certain ordinances, provided they agree with the general tenor of the ancient customs, which form what may be termed the Manks common law. The power of the Keys is judicial as well as legislative. Appeals may be made to them from the inferior courts, and in all such cases, as well as in actions, their decision is final, unless the cause be carried before the king in council. They always determine by a majority, and in their legislative capacity they conduct their deliberations in private. Foreigners, as well as natives, are eligible to seats in this house, the only requisite qualification being the possession of land. A grand court, consisting of the whole four estates of the island, continues to be held every year at the Twynald-Mount, where all new acts are publicly read, and thenceforth become binding on the people, who are supposed to give them their concurrence. The governor is nominated by the king. He is chancellor *ex officio*, and by himself or deputy is empowered to hear appeals from the decision of minor tribunals in all civil questions, except such as relate to the possession of land, which can only be entertained in the Keys. All arrests, both civil and criminal, are granted in his name, and he can, at pleasure, convene the different branches of the legislature; but there are some doubts respecting his powers of prorogation. He likewise possesses the prerogative of coining, as the representative of the ancient monarchs: but no money is legal till declared to be so by an act of Tynwald.

The council of the governor consists of five persons, who hold their seats *ex officio*. These are the lord bishop,

the water-bailiff, the attorney-general, the clerk of the rolls, and the archdeacon. Several other officers, both of the church and state, have likewise claimed this privilege, but their claims have not yet been recognized. The deemsters, of whom there is one for the northern, and another for the southern district of the island, are judges both in common and criminal causes. They have each a distinct court, answering to those divisions where they preside, and give judgment without the intervention of a jury. The situation of deemsters is of great dignity, and their influence over the people formerly resembled, in some degree, the civil authority of the ancient Druids, whose institutions were, in all probability, the original foundations of their authority. In the criminal courts, the usage observed by the Saxons before the conquest is still retained. The bishop, or his deputy, sits with the governor till sentence is to be pronounced, when, instead of the usual enquiry of guilty, or not guilty, the deemsters ask, "Vod fir charree fire?" signifying, "May the man of the chancel, or he that ministers at the altar, continue to sit." If the question is answered in the affirmative, the bishop, or his substitute, continues sitting, but if sentence of death is to be pronounced he rises and leaves the court.

The other chief civil officers of the island, besides those already noticed, are the lieutenant-governor, who has little power, except in the absence of the governor; the high-bailiffs, one in each of the four towns, the coroners or sheriffs, the lock-men or bailiffs, coroner's officers, and the constables. The coroner is chief keeper of the peace, and is authorized to arrest any one who breaks it. He likewise sees that the governor's arrests are put in execution, has the impannelling of the juries, and the charge of enforcing the sentences of the courts of law.

Laws.—To give a detailed view of the laws of this island, would occupy a greater space than can with propriety be permitted in an article like the present. The more prominent features and characteristic peculiarities by which they are so distinguished seem, however, to have a more than ordinary claim to a distinct and ample exposition. At an early period, the Manks constitution and government being wholly arbitrary, the will of the sovereign, or of his judges, was probably the only principle which regulated the decisions of their courts of justice. This much at least is certain, that no laws of any description were ever promulgated till towards the middle of the fifteenth century, when the independence of the House of Keys was fully established. Since that time, justice has been administered, generally, with strict impartiality, either according to the statutory enactments of the Tynwald, or the common law of the country. The laws affecting the lower orders were, so late as the year 1777, oppressive and tyrannical. They even regulated the amount of the wages of workmen, and ordained that all children not brought up, or put apprentice to any trade, should be ordered into service, except in the event of the parents being old or decrepid. Servants refusing to work on the legal terms were imprisoned till they gave their compliance, and no person who had done a day's work for any compensation, could leave the island before he or she had arrived at the age of twenty-five years. On the subject of marriage, the laws were nearly silent till the year 1757, so that persons of any age or condition might marry without either licence or the publication of banns. Since that time, however, the marriage regulations have been, in some respects, similar to those of England, but, in others, they are yet essentially different. The ceremony is according to the forms prescribed by the Protestant church, but no person without a special licence from the ordinary can enter the

MAN, ISLE OF.

the state of wedlock till he has received the sacrament. By the Manks law, the husband and wife are not so completely united into one person as they are by the English. Marriage is, indeed, regarded as a species of partnership, but it does not give an exclusive title to estates, either real or personal. In fact, the landed property of each always remains distinct, but the parties possess every thing else in common, with this difference, that the husband may bequeath his possessions to whom he pleases; but since the act passed in 1777, the wife can only leave her's to the children of the existing union. In case of either being found guilty of treason or felony, only the criminal's share is liable to forfeiture. Fathers are obliged to maintain their children till they reach the age of fourteen, when all legal obligation between them ceases. A child may then claim any legacy, and depart, if he is so inclined; but if he remains, his father is entitled to the interest or use of his money as a compensation for his maintenance. Upon the death of the husband without a will, the widow enters upon her share of the property only, but in the event of the woman's demise intestate, the husband enters upon the whole. Where there is only one child, and the father neglects to appoint a guardian, his kindred are entitled to the custody of it; but if there are two children, the mother takes care of the eldest, and the second is taken care of, as an only one would be. A child, though a bastard at the time of its birth, becomes legitimate by the marriage of the parents within three years after that period. At the decease of his father the eldest son succeeds to his heritable property, and if there are no sons, the eldest daughter, even though the estates are entailed. The origin of this custom, so different from the practice in other feudal countries, is attributed to the bravery of the southern women in assisting their husbands in a great battle, and enabling them to gain the victory.

All the lands of this island at an early period belonged to the lord or sovereign: even so lately as the sixteenth century, real property could not be alienated on any pretence without his special consent, or that of his three principal officers. The occupants were styled the lord's tenants, and were subject to the payment of a fine or rental. Attempts were made about the middle of the seventeenth century to render all the tenures leasehold, either for three lives, or for twenty-one years. This produced a warm dispute between the sovereign and the land-holders, which was not terminated till the year 1703, when it was agreed that the latter should retain their possession so long as they continued to pay the fines and rentals settled between them and the earls of Derby's commissioners after the year 1643. The period of a lease is restricted to twenty-five years, and a mortgage, not redeemed within five years, renders the parties liable to the fine of alienation.

The whole island was formerly divided into six hundred portions, called quarter-lands, but Feltham says, their number is now increased to seven hundred and fifty. All other estates are either allotments out of, or encroachments upon, these. The titles to property are, as may be supposed, various and similar in their nature, though sometimes different in their limitations, to those acknowledged by the laws of England. Unmolested possession for ten years, till very lately, constituted a sufficient right to any species of property; but the term is now extended to twenty-one years. Every proprietor possesses the privilege of feeding a certain number of cattle upon the commons, which abound in various parts of the isle, and every inhabitant has the privilege of quarrying stone and digging peat for his own use. All wrecks not claimed within a year and a day, and all mines, belong to the lord by his prerogative. Game, likewise,

was anciently his property. Goods taken in distress, or execution, must remain one month as a pawn, redeemable by the tenant, or defendant, on paying of the rent, or of money recovered in an action at law.

But the most marked peculiarity in the Manks law is, that no arrest can be granted against a landed proprietor or native, to imprison or hold him to bail in a civil action, unless there appears some just cause to conclude that he intends leaving the island without making satisfaction to his creditors. Such persons as are prosecuted for a foreign debt can only be obliged to find bail for his personal appearance, and for the forthcoming of all his property on the island, except his clothes and money, which remain his own. It is from the operation of this latter law that the unfortunate, and too often the fraudulent also, find an asylum here from the prosecution of their creditors. By converting the residue of the property into money, they are enabled to reside on this island in comfort, and without the danger of legal molestation. If, however, there is any thing clearly shewn to be so criminal in the conduct of any individual as to infer the pains of law, the governor generally grants a warrant for delivering him over to the justice of the country to which he belongs.

By the laws relative to public wrongs, here no offender can be convicted of any capital crime, except by a jury at the court of general gaol delivery. Formerly, indeed, a person who made an attack upon the lord, or his lieutenant, could be condemned immediately, without any form of trial, but the practice has been long obsolete. This offence was deemed treason; so likewise was the striking of any of the lord's servants in his presence, robbing him in court, constraining him to hold a Tynwald court, relieving or concealing a rebel, counterfeiting the current coin of the island, and bringing in any false money and making payment with it. Thus, even copper coinage is treason, contrary to the law of England, which confines it to the counterfeiting of gold and silver money.

For bigamy, or polygamy, there is no punishment by the Manks law, even at the present day; but the second marriage, being illegal, is null and void, and the children are, consequently, regarded as bastards, and deprived of their rights to inherit the property of their parents. Suicide is punished by forfeiture. In the event of a rape on a married woman, there is no alternative but death; but if the woman is unmarried, she has her choice to hang, behead, or marry the offender. What is remarkable, there is no instance of a conviction for this crime upon record, and only one traditionary, and in that case the lady is said to have adopted the last condition, just at the moment when her ravisher was about to be launched into eternity. Assault and battery are punished by fine and imprisonment, according to the decision of the governor or deemster, without the intervention of a jury. It is felonious to enter a house with burglarious intention, even though it should be without a door, provided two ticks are placed across the entrance. Forging is not accounted criminal, at least the offence is only regarded by the law as a civil debt. Theft, above the value of sixpence-halfpenny, is capital. Below that value the crime is termed petty larceny, and subjects the offender to corporal punishment and imprisonment at the discretion of the court. To convict for felony one respectable witness is now sufficient, if his evidence is supported by probable circumstances.

Religion.—The established religion of Man is the same with that of England. Toleration, however, having extended its beneficial influence here, as in other parts of the British empire, Dissenters of almost every denomination are prevalent. Among these the most numerous sect is undoubtedly the

MAN, ISLE OF.

the Methodists, who form at least one-tenth of the whole population. The establishment is placed under the direction of a bishop, assisted by an archdeacon, two vicars-general, and an episcopal registrar. The patronage of the see still continues in the Athol family, but the nomination of the superior clergy must be approved of by his majesty. The bishop is consecrated by the archbishop of York as metropolitan of the diocese, and enjoys all the privileges and spiritual rights of other bishops; but his see not being baronial, he is not entitled to vote in the house of lords. He has, however, a seat, as Mr. Wood supposes, by courtesy, above the bar. The first bishop of Man was St. Germain, to whom the cathedral church is dedicated. At that time the diocese was limited to the boundaries of the island, nor did it extend beyond them till the conquest of the western isles by the Norwegians, about the commencement of the twelfth century. When the *insula Sodorensis*, so called from the bishopric of Sodor, a small village in Iona, and once "the metropolis of learning and piety," were united to it; the whole formed one bishopric, styled Sodor and Man. The metropolitan at that period was the archbishop of Drontheim. After the annexation of the island to the crown of England, the conjoined bishoprics were separated.

Surface and Rivers.—The general aspect of this island presents considerable diversity of hill and dale. A chain of mountains, moderately high, divides it nearly into two equal portions, in a direction from N.E. to S.W. This range is broken only at one place, between mount Kreevey and South Barrule. The most conspicuous summit of the whole is Snawfel, the height of which, as taken by the barometer, appeared to be 580 yards above the level of the sea. The two Barrules, which form its northern and southern extremities, are nearly of the same elevation. Between North Barrule and mount Kreevey arise several rivers, which empty themselves into the sea at Ramsey, at Laxey, and at Douglas. Of these rivers, that of Ramsey is by far the largest, being so much influenced by the tide, from the level nature of the district through which it flows, that it is navigable for vessels of considerable burthen at the distance of more than two miles from its mouth. The other rivers in the island are very shallow and inconsiderable streams. Here is a great deficiency of wood.

Soil and Climate.—The soil of this island is various. Towards the south parts the greater proportion is loam, but stiff clays likewise abound, and in some spots the surface exhibits a fine light sand. The northern district consists principally of a sandy loam, with a bottom of clay or marle. Here is an immense tract of land called the *Curraugh*, extending nearly across the whole island, from Ballaugh to Ramsey, which was formerly a bog, but is now drained and produces excellent grass crops. In a few places of this tract is a remarkable layer of peat, which stretches itself several miles under a stratum of gravel, or earth. The thickness of the layer varies from two to three feet, and that of the gravel, &c. from two to four feet. In other parts of the same tract the peat has been removed to the depth of ten feet. The climate is generally reckoned milder in winter than that either of England or Ireland in the same latitude, as, from the proximity of every part of the isle to the sea, frost and snow are seldom of long continuance. The summers, however, are less warm, and gales of wind and falls of rain, during this period, are extremely frequent, often occasioning very considerable damage, not only to the fruit, but also to the grain-crops.

The mineralogy of the Isle of Man offers very few objects of interest or importance. More than two-thirds of the

whole surface rests on strata of wacke-slate, or clay-slate. The hills, called North and South Barrule, are composed of mica-slate, covered with clay-slate; Mount Kreevey consists of the same materials, traversed by many large veins of quartz, two or three feet in thickness. On the north side of South Barrule appear some blocks of granite, containing a quantity of silvery mica, reddish feldspar, and grey quartz. In the neighbourhood of Castletown is found a blueish-grey lime-stone, intermixed with impressions of shells and other marine exuvia, and intersected by small veins of calcareous spar. This lime-stone lies above a stratum of wacke slate, from which it is separated at some points by a thin layer of white clay, which does not in the slightest degree effervesce with acids. Near Pool-vash-bay this mineral becomes so highly indurated, that it is quarried below high-water mark, as a tolerable good marble for tomb-stones. Not far from Langels a small quantity of compact brown iron-stone is found, lying under a breccia composed of pieces of quartz in a siliceous base, and bearing some resemblance to horn porphyry. The Calf of Man, which is separated about 100 yards from the main, consists entirely of a glossy blueish-grey clay-slate, lying more inclined to the east, and more unequally stratified than the slate-rock on the opposite shore. At Kirk Arbovy are shafts of lead-mines now entirely deserted. Breda-head copper-mine is chiefly the sulphuret of that metal. The mines of Foxdale, celebrated for their fine lead-glance, are now entirely drowned by the tide; so that the only mines at present wrought on the island are those of Laxey, which produce a very considerable quantity of lead and copper, both of excellent quality. Crystals of iron pyrites are occasionally found in different places.

From these few facts the geologist will perceive that this island consists partly of primitive clay-slate and mica-slate, resting probably upon granite; of grey wacke-slate, and of lime-stone which seems to belong to the rocks of transition of the Wernerian geognosy; of sand-stone of the earliest formation, and of sand resting upon clay.

The agriculture of this island, though much improved of late years, still continues at a very low ebb. More than a third of the whole surface lies in an uncultivated state, and entirely appropriated to the feeding either of sheep or cattle. The value of land in this condition varies from five to ten shillings *per acre*; but arable land often rises above two pounds. The enclosures are formed in general of embankments of earth, unaccountably crooked and irregular, and containing from four to ten acres. Barley constitutes the chief grain raised by the farmers, as the soil and climate are thought to agree better with its growth than with that of any other corn. Potatoes and turnips are likewise cultivated in great abundance. Crops of flax are very common in every part of the island; almost every cottager growing a small quantity, both for home use and exportation. Hemp is sown in gardens, and on rich enclosures, but very rarely in the open fields. The plough in common use is of a light construction, and generally procured either from England or Scotland. Owing to the small size of the horses, four are requisite to turn a furrow four inches deep. The Manks harrow and roller are generally of a good make, though light; but with respect to wheel-carriages, a total ignorance of their proper construction prevails. Cart-wheels are invariably very narrow and small. Drilling and hoeing machines are little used.

The native sheep of the island are small and hardy, bearing a resemblance to the South Down; when properly fed, their meat is of the most delicious kind. This is still called the mountain breed, being reared entirely on the hills and uplands; but in the lowlands a larger species has been introduced.

MAN, ISLE OF.

roduced. Besides these there is a third breed, called the Laughton, which affords very fine wool of a dark buff colour, much used by the inhabitants in making stockings. Many hundred head of cattle are fattened annually for exportation; and pigs and poultry are reared in great abundance, as are also geese and ducks; but turkies are rather scarce. The manure chiefly used by the farmers is farm-yard dung, or, if near the shore, sea-weed. A regular rotation of crops is little understood or practised, and summer fallowing scarcely ever occurs. The indolent disposition of the men, (for the women are lively and active,) joined to the attractions of the herring fisheries, and the operation of the tithe system, are radical obstacles here to agricultural improvement, which even the Cumberland Society, lately extended to this island, will find it difficult to remove. Intimately connected with this subject is the state of the

Roads and buildings, both of which have of late been greatly improved. Forty years ago, the former were dangerous for carriages even in summer, but at present they are very good during that period; though, owing to the clayey nature of their composition, they sometimes become impassable for several days in winter. Houses of the best sort, both in town and country, are constructed of hewn stone; and those of an inferior description of rough stone. Farm-houses and offices are usually small, irregular, and ill built: a few modern ones, however, are on a better plan. The meaner cottages consist principally of fods of earth, with a thatch of straw. The bridges are mostly in tolerable condition, being built and supported at the expence of the public, and requiring an act of Tynwald to authorize their erection.

Towns and Villages.—This island possesses a number of small towns and villages, situated principally on the coasts. The chief of these are Castleton, Douglas, Peel, and Ramsay. Castleton is considered as the capital, being the residence of the governor, and the seat of the superior courts; but Douglas is of more importance in a commercial point of view. In the centre of Castleton is Castle-Rushen, an irregular fortified building of stone, said to have been erected in the year 960, by the Danish prince Guthred, who was buried within its walls. The stone glacier, which furrows it, is supposed to have been the work of cardinal Wolsey. This fabric was the ancient mansion of the kings of Man, where they lived in all the warlike pomp of feudal magnificence. Douglas, only a century ago, was merely a group of huts; but it is now the most opulent and best built town on the island. The duke of Athol's principal residence is situated in this vicinity. Ramsay is a neat town, where the dean of the northern district resides, and holds his courts. Peel is likewise a pleasant village, and more distinguished, than any other spot in Man, for its remains of antiquity. Peel castle, placed on a small island, divided from the main by a narrow channel, deep during the flow of the tide, but easily fordable at its ebb, is a very noble remnant of ancient architecture. Near it are the ruins of two churches: one dedicated to St. Patrick, of uncertain origin; and the other called St. Germain's, or the cathedral, which was constructed about the year 1245.

Commerce and Manufactures.—None of the mechanical arts having yet reached any degree of perfection in Man, its manufactures are few, and of little value. Indeed, the only ones worthy of observation are those of Douglas, where sheeting, towelling, sail-cloth, and sack-cloth are made. In commercial concerns, however, it is of more importance, great quantities of lead, cattle, sheep, fowls, butter, and eggs, being shipped from hence to England. Some strong linens and sail-cloth likewise form articles of export, but

the chief source of opulence here, as in Shetland, is the herring-fisheries; for the smuggling traffic, which proved so advantageous in former times, is now almost entirely cut up. About five hundred boats are regularly employed in the fisheries every season, beginning with July, and ending with September. A few years ago it was customary for the fishermen to offer up a prayer for success on leaving the harbour, but that practice has fallen into disuse. As yet, however, they make it a rule never to sail either on a Saturday or Sunday evening, lest the sabbath should be violated. The ordinary size of the boats is about eight tons, and their value, including the nets, &c. somewhat more than 80*l*. Every night's produce is divided into nine shares, of which two belong to the proprietors of the vessels, one to the owners of the nets, and the residue to the fishermen. Of the white herrings, the greater proportion are sold in England, but most of those termed red herrings are exported to the different ports of the Mediterranean. Previous to the commencement of the late war, a salmon-fishery was established here upon an extensive scale, but since that period it has much declined. The imports to the island consist of manufactured goods of almost every description, together with coal, wine, brandy, and other spirituous liquors: the balance of trade is greatly against the island. The deficiency, however, may probably be made up by remittances to the numerous strangers, who, in order to avoid the visits of a bailiff, or the extravagance of English living, resort hither either as a temporary or permanent retreat.

Antiquities.—The Isle of Man contains considerable vestiges of ancient times. The little Isle of St. Michael is joined to the Main, at Longnefs-point, by a high breast-work, about one hundred yards in length, and on the Isle itself are the ruins of a circular fort, built by one of the earls of Derby. On the road from Castle-town to Douglas, at the distance of two miles from the former, stand the venerable remains of Rushen-abbey, founded in the year 1098 by prince Macmarus. This establishment consisted of an abbot and twelve monks of the Cistercian order, who were so celebrated for their hospitality, as to acquire the title of almoners of the poor. The abbot, in later times, became a baron of the island, and was invested with the power of holding courts in his own name. Many of the kings of Man were interred in this monastery. Not far from Douglas appear the remains of another monastery for female votaries, said to owe its original foundation to St. Bridget, in the sixth century. The prioress of this institution was likewise a baroness of Man, and held courts in her own name. Immediately adjoining to Laxey, on an elevated site by the road-side, is a small circular range of stones, some of them standing erect, and others leaning towards the centre, which has apparently formed a *kist-vaen*, but is now mutilated. This monument bears the name of the *Clowen-stones*. The parish of Kirk-Andreas, north of Ramsay, is particularly distinguished by a variety of ancient remains. The entrenchment at Ballachury, situated on a small natural eminence, is in more complete preservation than, perhaps, any other erection of the same kind in the British dominions. It is of a square form, and has a very noble bastion at each angle; the whole surrounded by a wet foss of ample dimensions. Many barrows are to be met with in this neighbourhood, some of which have been opened, and earthen urns discovered in them. In the parish church stands a square stone pillar, with a Runic inscription, thus translated by Mr. Beufort. "The son of Ulf of the Swedri (or Swedes) erected this cross to the warrior Astarin, the son of Cunnu." Many other Runic inscriptions and tumuli appear in various parts of the island; indeed, they are probably more numerous

rous here than in any other district of a similar extent in Europe. The Tynwald is the only object that now remains to be mentioned. It is situated about three miles from Peel, near the side of the high-road leading to Douglas. The name of this artificial mount is compounded of the British words Tyng and Val, signifying the juridical hill. This monument of ancient days is in the form of an obtruncated cone, divided into three stages or circles, regularly advanced three feet above each other, but proportionally diminished, both in circuit and width, the nearer they approach the summit. The whole was formerly surrounded by a ditch and rampart of earth, inclosing a space, on which stood a small chapel dedicated to St. John, lately re-built. Concerning the first erection of this mount nothing is known, either from history or tradition; but judging from its name and appropriation, it would seem to have been constructed by the aboriginal inhabitants of the island.

Population, and Means of Defence.—The number of inhabitants in this island has varied much at different periods. In the time of Bede, it is said by that author to have contained only 300 families. Hollinshed, who wrote about the year 1584, observes, "there were formerly in this island 1300 families, but now scarcely half that number." In 1726, the population was 14,511; in 1757, it had increased to 19,144; and, in 1792, to 27,913. At present it is thought to exceed 30,000 persons, an increase partly owing to the improved state of agriculture, and partly to the greater number of strangers who now take up their abode in this land of freedom from taxes and arrests. The military establishment of the island consists solely of a regiment of fencibles, who are enlisted voluntarily, and receive a bounty of three guineas. Their pay is the same as that of English regiments, and the service being easy, most of the individuals which compose them are engaged in some trade or business, for here military duty is not reckoned incompatible with the pursuits of civil life.

Language, Manners, and Customs.—From the number of strangers continually flocking to this island from Great Britain and Ireland, and the commercial intercourse that subsists between them, it may reasonably be supposed that the English language is usually spoken in the towns on the sea-coast. In the interior, however, the original Manks language still prevails. This last is merely a dialect of the Gaelic, or that used in the Highlands of Scotland, with a commixture of Welsh, Saxon, and Danish words. The radices, indeed, are chiefly Welsh. The New Testament, and several scriptural publications, have been translated into the Manks tongue; and in the country parishes it is customary to preach in this language and in English every alternate Sunday.

With respect to the character of the people in this island, it is generally observed that the men are habitually of a lazy and indolent disposition. This is not improbably the consequence of the herring-fisheries, in which the greater part of them are engaged; for such pursuits, in certain conditions of society, are, beyond doubt, prejudicial to the more active concerns of agriculture and the arts. In fine, wherever fisheries are established upon a scale sufficiently extensive to afford employment to the men, the affairs of the field are left to the women in a great measure; and this is precisely the case in Man, the females being both the reapers and threshers of all the corn in the island. Hence it happens, that the women are as remarkable for their activity and sprightliness, as the men are for their indolence. Unfortunately, however, an extreme laxity of opinion prevails among them in respect to chastity. A servant girl, by becoming a mother, does not suffer any degradation of character. The event is, there-

fore, of no unfrequent occurrence, and is probably the reason why women of the town are scarcely ever to be met with, even in Douglas. Like the Highlanders and Swifs, the Manks are much attached to their native vales and mountains, as well as to their ancient customs and laws. They conceive themselves to be independent of Great Britain, and were much affected by the sale of the island, because they feared it would blend the countries. A great fondness for litigation, and an uncommon love of hospitality, are striking, though somewhat contradictory, features, in the Manks character. So much, indeed, are they naturally disposed to charity, that poor's rates are wholly unknown, and there is no such institution as an hospital, or workhouse, in the whole island. Every parish, however, has a charity-school, and generally a small library, both of them supported by voluntary contributions, or funds arising from legacies or donations. Neither shoes nor stockings are worn by the lower orders, excepting on particular occasions. A blue cloak is the common body-dress of the women, and strangers are usually habited in a sailor's jacket, and trowsers of the same colour. This dress is termed the Manks livery. The belief of fairies, and such imaginary spirits, still firmly maintains its influence over the inhabitants of this island; a circumstance ascribed by many to the natural gloom and solitude which pervades every portion of the country. These airy spirits are divided, by such as pretend to skill in visionary lore, into two classes, the one comprehending the playful and benignant sprites, and the other the fullen and vindictive ones. The former, gay and beautiful, seek the margin of the brooks to sport among the bushes, or dance on the tops of the adjacent mountains, while the latter find a habitation in the hideous precipices of the sea-shore, and to their malignant influence the Mankfman imputes every calamity which may assail him. A belief in the second sight, and in warnings and foreknowledge of their own deaths, is no less common than this fairy superstition. Many, in their lonely wanderings, have met with a visionary funeral, following them wherever they might turn, awfully portentous of the approaching dissolution of the devoted victim. These opinions are not confined to the lower orders alone, but are credited by individuals even of high respectability. In other respects, however, the superior classes differ completely from their fellow islanders, and assimilate themselves as much as possible, both in dress, habits, and sentiments, to the same orders in England. An Account of the past and present State of the Isle of Man, by George Woods, 8vo. 1811. A Tour through the Island of Man in 1797 and 1798, by John Feltham, 8vo. 1798. A Journal kept in the Island of Man by Richard Townley, esq. 2 vols. 8vo. 1791.

MAN is also an island in the Pacific ocean, in St. George's channel, between New Britain and New Ireland, about 50 miles in circumference; discovered by captain Carteret in the year 1767. S. lat. 4°. E. long. 151° 25'.—Also, a town of Hindoostan, in the Carnatic; 11 miles W. of Tricolore.

MAN at Arms, in *Ancient Military Language*, derived the appellation from being completely armed de cap-à-pied, or from head to foot. The men at arms formed a part of the cavalry of our ancient English armies soon after the conquest, which consisted of knights, or men at arms and hobblers; as the infantry was composed of spear and bill men, cross-bow men, and archers. However, in garrisons the men at arms occasionally served on foot. These men at arms were chiefly composed of the tenants in capite, holding by military service, or their substitutes, sometimes called ser-vientes. The defensive armour of a man at arms was a hauberk of double mail, composed of ringlets of iron linked together

together like a net, which covered the body, and to it were joined a hood, breeches, stockings, and sabatons or shoes of the same construction: the hands and arms were also defended by gauntlets and sleeves of mail; the hauberk was the proper armour of a knight; an esquire might wear a shirt of mail over his gambeson, but might not use the hood, breeches, hose, nor sleeves of mail. Sometimes, but not commonly, men at arms wore habergeons made of plate mail, formed of small round plates of iron, laid one over the other like scales of fish. Sometimes over the hauberk, but commonly under it, was worn a loose garment called the *gambeson* (which see), descending to the knees, stuffed with wool or cotton, and designed for deadening the strokes of the sword or lance, which, though they might not divide the mail, would severely bruise the body without the interposition of the gambeson. Under or between the hauberk and gambeson, a breast-plate of forged iron, called a *plastron*, was occasionally put on; over which all men of family wore surcoats of satin, velvet, or cloth of gold or silver, richly embroidered with their armorial bearings. By a strap hung over the neck, the men at arms carried a shield made of wood, covered with leather, bound or strengthened with iron or brass, having handles on the inside for *bracing* it, which was the term then in use for putting it over the left arm, *Fr. bras*. These shields were for at least a century after the conquest of a triangular form, pointed at the bottom, and a little convex in the direction of their breadth. The helmets worn by the men at arms were of different forms; some conical or pyramidal, with a small projection, called a "nasal," to defend the face from a transverse stroke; some cylindrical, covering the whole head down below the chin, with apertures for sight and breath; and others in which the face was totally uncovered. Helmets with beavers and vizors do not seem to have been in use till the middle of the fourteenth century, about which time the hauberk was exchanged by many of our men at arms for plate-armour, so called from being formed of plates of iron. On the crests of their helmets kings frequently wore their crowns, earls and dukes their coronets, generals or other officers of rank either their armorial cognifances, or any other device at pleasure. This was done to give them a more terrific aspect to their enemies, and to render them conspicuous to their own officers and soldiers. To the above list of defensive armour we may add the war-saddle, whose arcon of bows of steel covered the rider as high as the navel. The knights of the three or four reigns next succeeding the conquest, commonly wore the pryck spur, which had only a single point, after which the rouelle, or wheel spur, came in fashion, some of which rouelles were six inches in diameter. Thus enveloped and loaded with incumbrances, we need not wonder, that in the heat of summer, and dust, and pressure of an engagement, men at arms should be suffocated in their armour.

The offensive arms of a horseman, or man at arms, were a sword or swords, a lance, and a small dagger, called a "Mifericorde" (which see), and also iron maces suspended at their saddle-bow. The horses of the men at arms were no less encumbered than their riders; their faces, heads, and ears, were covered over with a sort of mask, so contrived that they could not see right before them and be terrified. This mask was called a "chafron," or shaftfront. Besides other appendages, which it is needless to enumerate in detail, they were occasionally covered all over with mail, or linen stuffed and quilted like the gambeson, and adorned with rich embroidery. Horses, thus covered, were called "barded," and corruptly barbed horses. These war-horses, for preventing their being fatigued, were not mounted till

VOL. XXII.

the men at arms were certain of coming to action, and they had commonly hackneys for riding on a march. Barded horses were in use in our armies at the time of king Edward VI. When plate-armour came into general use, about the middle of the fourteenth century, the accoutrements of the men at arms were a close helmet, with a visor, or visor and beaver revolving on the same pivot, and capable of being lifted up or let down. The neck and throat were defended by a gorget, or hallercet, the body by a cuirass, the arms by brassarts, the hands by gauntlets, the shoulders by poultrons, the thighs by cuissarts, and the legs by iron boots, called greaves, and sometimes by boots of jacked leather. Under all these was worn a jacket of thick luntian, or buff leather. About the time of queen Mary the appellation of men at arms, signifying the heavy-armed cavalry, seems to have been changed to that of spears and lances, and afterwards to cuirassiers. The armour of a lancier was much the same as that we have described: their offensive weapons were a *lance* (which see), of sixteen or eighteen feet in length, a sword, and petrenels, which last were somewhat longer than the pistols then in use.

The hobilers (see *HOBILER*) were a species of light horsemen, chiefly calculated for the purposes of reconnoitring, carrying intelligence, harassing troops on a march, intercepting convoys, and pursuing a routed army: their horses were small and unable to resist the shock of a charge. Some derive the appellation from a Danish word, signifying a mare; but this is not likely, as the men at arms were chiefly mounted on stone-horses, and in the days of chivalry it was considered a degradation for any knight or man at arms to be seen mounted on a mare. This name was more probably derived from the hobbies or small horses which they rode. The establishment of hobilers has been commonly, but erroneously, referred to the reign of Edward III.; but they are mentioned as part of the British army that attended king Edward II. into Scotland, in the year 1322. The name seems to have been totally lost about the latter end of the reign of Henry VIII. or queen Mary; these troops being then distinguished by the appellation of demy-lanaces and light horse. The arms and appointments of a hobiler, as directed by king Edward III., were a horse, a hagueton or armour of plate, a bacinet, iron gauntlets, a sword, knife and a lance. Sometimes archers were mounted on light horses, whence they were styled hobiler-archers. *Grofe's Mil. Antiq. vol. i.*

MAN, in the *Materia Medica of the Ancients*, a name by which manna has been called by the oldest writers. There has been, however, some confusion in the history of manna, owing to the too general use of this word, the same authors using it as the name of several other substances of very different kinds, which came to their hand in forms of small granules, or flakes like the manna. The fragments of frankincense, in particular, were called by this name, with the addition of the word *thuris*, and sometimes without man or men standing singly for that drug.

MAN, in *Mythology*, the name of a deity among the ancient Germans; whom they supposed to be the son of Tuif-ton, and celebrated with songs, as the founder of their nation: and to him they consecrated their groves and forests.

MAN the Capstan, on board a *Ship*. See *CAPSTAN*.

MAN the Side, or Ladder, is when an officer or any person of distinction is at the ship's side ready to come aboard, the men are commanded to wait, and help him up the side.

MAN the Top, or Yard, a word of command for the men to go up to the top, or yard, for some particular service.

MAN of War, the same with a ship of war. See *SHIP* and *RATE*.

MAN of War Key, in *Geography*, a small island among the Bahamas. N. lat. 26° 20'. W. long. 77° 15'.

MAN of War Keys, small islands and rocks in the Spanish main, near the Mosquito shore. N. lat. 12° 55'. W. long. 88° 35'.—Also, small islands at the entrance of West harbour, on the S. coast of the island of Jamaica.

MANA, a town of Peru, in the diocese of La Plata; 15 miles S. of Potofi.

MANA, in the *Jewish Customs*, a kind of offerings made in the temple, otherwise called Mincha. The word manna is used in the Septuagint.

MANAAR, or MANARA, in *Geography*, a small island, the name of which is derived from the Malabar words *man*, sand, and *aar*, river, lying off the coast of Ceylon, about 60 miles S.W. of Jafnapatam. Manaar was formerly more flourishing than it is at present. The fort was small, but strong, square, and regular. The city now consists of only a few tiled houses, government offices, and some low huts, inhabited by boatmen and fishermen. At low water the island of Manaar is separated from Ceylon by a small winding river; but when the tide flows, this river appears as an arm of the sea, and is about three miles over. It is called the "gulf of Manaar." Manaar lies in N. lat. 9°, and is about 2½ German leagues in length, and one in breadth, including a salt river. The fort is situated near the channel or strait which divides Manaar from Ceylon. There are besides seven villages in the island. At the extreme end, where boat is taken for the coast of Coromandel, there are four or five churches for the natives and Malabar Christians, besides that of Carcal used by the Dutch. The island is barren and sandy, with a few palmiras and cocoa-trees scattered here and there. The surrounding sea supplies abundance of fish. The passage from this island to Ramiferam, on the Coromandel coast, is not above 12 or 14 leagues, but the passage is interrupted by innumerable shallows and sand-banks, many of which are high and completely dry, except during the monsoons. Adam's bridge, or Ramas bridge, is formed by a line of sand-banks, which runs quite across from Manaar to Ramiferam. (See ADAM'S BRIDGE.) It is an universal opinion among the natives, that Ceylon was either the Paradise, in which the ancestor of the human race resided, or the spot on which he first touched on being expelled from the celestial paradise. Adam's bridge was, as they conceive, the way by which he passed over to the continent; and some of them imagine, that the gulf of Manaar, like the Red sea in scripture history, closed after him to prevent his return. It is, however, universally believed, that Ceylon, at a distant period, formed a part of the continent, and was separated from it by some great convulsion of nature. In addition to other circumstances that favour this presumption, we may observe, that the appearance of the soil and the surface of the country are very similar on the W. coast of Ceylon and the opposite continent. The situation and appearance of the Maldive islands, on the other side of the peninsula of India, agree with those on the W. coast of Ceylon, to support the opinion that this continent must have been once much more extensive, till the ocean, from some unknown cause or other, exceeded its former boundaries.

The gulf of Manaar, though too shallow to admit vessels of large size, is not altogether useless for the purposes of commerce. Sloops, donies, and various small vessels, convey goods by this passage from Madras and other places on the Coromandel coast directly to Columbo, instead of rounding the islands by Trincomalee and Point de Galle. Notwithstanding the obstructions that occur in this passage, the Dutch have found means to carry on a constant traffic in this

way between the western coast of Ceylon and their factories of Tutucoran, Vipar, Manapar, Ponical, and Kikkerre. Coarse cloths and calicoes were the chief articles thus imported by the Dutch, and in return they carried back areca and cocoa-nuts, betel leaf, fruits, arrack, and coya, or cordage made from the cocoa-tree. All these places are now in possession of the English, who may avail themselves by the traffic which they afford.

The short passage from Ramiferam to Manaar forms a speedy communication of intelligence to people of business; and government has boats stationed here for the purpose of conveying the "tapal," or letter-bags, between Ceylon and the continent. The "Peons," a cast of people employed for this purpose, travel at the rate of five miles an hour, and they are relieved at certain stages by fresh runners. They usually go from Columbo to Manaar, a distance of 160 miles, in three days. Here they take boat, and cross over by Adam's bridge to Ramiferam, and then proceed along the Coromandel coast to Madras. An express will generally run from Columbo to Madras in eight days. See RAMISERAM.

The Dutch built a fort on the island of Manaar, with a view to command the passage and the communication with the continent by Adam's bridge. It was principally intended to prevent the subjects of the king of Candy from smuggling over any of the produce of the island, particularly spiceries; and also to cut off all intercourse between that prince and those of the continent, by which he might have formed alliances dangerous to their interests. The protection of the pearl-banks and pearl-fishery, which lie at no great distance from this island, was also another object for constructing a fort here. It also contributed considerably to the revenues of government, as a station where certain duties are levied on the vast quantities of calicoes, coarse muslins, cottons, and other articles, brought through this passage to Columbo by the Moors, Malabars, and other inhabitants of the continent. These circumstances are sufficiently important in order to keep in this place a constant garrison, the expence of which is greatly overbalanced by its advantages. The garrison stationed here consists only of a company of Malays or Sepoys, under the command of an European officer; but during the pearl-fishery, an additional force is sent from Columbo.

In proceeding along the coast of Ceylon from Manaar, the country is found to be sandy, wild, and barren, equally destitute of accommodation and provisions. The woods are so infested with wild animals, that it is very dangerous to travel along the roads here without a proper guard. The sea is skirted by a tract of low flat sand: but farther inland there are rice and paddy fields, with some scattered houses. This appearance continues about 30 miles to the southward of Manaar, when the wood and jungle again begin to approach to the shore, and to cover the whole surface of the country, till at Chilou the cinnamon woods shew the commencement of the district of Nigumbo. At Mantotte, near Manaar, there are some remains of antiquity. A Gentoo city is said to have stood there, and so have been built by that harmless people, who took refuge here: the vestiges of the embankment of a tank, and a number of brick ruins still remain. About 12 miles from Manaar lies the village of Aripoo, where the civil and military officers, who attend the pearl-fishery, reside during the season. This is the only place in their vicinity where good water can be procured. Here is a chapel for those of the Roman Catholic persuasion, who consist chiefly of the Parawas and Malabars, resorting hither during the season of the pearl-fishery. In the neighbourhood the woods are very full of deer and wild hogs.

hogs. At no great distance lies the bay of *Condatchy*; which see. Percival's Ceylon.

MANABACCA, a small island in the East Indian sea. S. lat. $3^{\circ} 59'$. E. long. $131^{\circ} 45'$.

MANABEA, in *Botany*, (from the Caribean name of one of the species, *Manabo*.) Aubl. Guian. 61. t. 23—25, Juss. 107, Lamarck Illustr. t. 70, is referred by Schreber to *Ægiphila*; see that article. Willdenow in his Sp. Pl. v. 1. 615, defines eight species of *Ægiphila*, three of which are the above plants of Aublet; one is *Æ. martinicensis* of Jacquin and Linnæus; another the *Nuxia* of Commerçon, Lamarck Illustr. t. 71; the three remaining ones being adopted from Swartz.

MANACA, a Brazilian bacciferous shrub, with an umbilicated fruit, like that of the juniper, containing three elliptical seeds, of the size of lentils; the part used in medicine is the root, which is great, solid, and whitish; its medullary substance, reduced to powder, has very considerable effects; but because it works too violently, both upwards and downwards, in the same manner as scammony, or the efula, it is usually given only to very robust persons, and then with correctives, in a just dose; it has somewhat of a bitterness and acor. The root, macerated in water, makes a fomentation, or bath, for those who are afflicted with wandering pains in the joints, especially such as are contracted by cold: the plant is used as a vulnerary by the Brazilians.

MANACHA, in *Geography*, a considerable town of Arabia, in the province of Yemen, the seat of the dola of Harras, and famous for its fairs.

MANACHOKE, a town of Hindoostan, in Bahar; 26 miles N.W. of Durbungah.

MANACIZO, a town of Naples, in the province of Otranto; 12 miles S.E. of Tarento.

MANACOR, a town of the island of Majorca, situated in a fertile plain, where persons of rank and of the most considerable property spend the summer season. Its population consists of about 7000 inhabitants. It contains a parish church, a monastery of Dominican friars, and an hospital for invalids. The productions of the soil in its vicinity are corn of all sorts, wines, fruits, vegetables, and pastures for flocks and herds. Proceeding along the coast from Manacor towards the east, you pass San Servera, and on the north of the village discover "Arta," containing near 8000 persons. This town, built in a mountainous situation, is one of the richest in the island: it contains a parish church, a convent, a public oratory, and two chapels of ease for the villagers. The land in the neighbourhood affords pasture for cattle of all kinds, and produces wine, olives, corn, and vegetables. The inhabitants cultivate the cotton tree very successfully, and make a large quantity of oil.

MANACUS, **MANAKIN**, in *Ornithology*. See PIPRA.

MANADO, in *Geography*, a small island and town, near the north coast of the island of Celebes. N. lat. $1^{\circ} 8'$. E. long. $124^{\circ} 32'$.

MANAGE, or **MANEGE**, an academy, or place for learning to ride the great horse; as well as for breaking horses to the proper motions and actions.

The word is borrowed from the French *manège*, and that from the Italian *maneggio*, or some will have it, *à manu agendo*, from acting with the hand.

In every manege is a centre, or place destined for vaulting round a pillar; a course or career for running the ring; and, on the side, are pillars, between which are placed the horses intended for high airs.

MANAGE, or *Manege*, is also used for the exercise itself, either of the horse or the rider. See HORSEMANSHIP.

MANAGUERA, in *Geography*, a town situated on the west coast of Madagascar.

MANAKIN, in *Ornithology*. See PIPRA.

MANAM, in *Geography*, a town of Africa, in Sugulmeffa; 16 miles E. of Sugulmeffa.

MANAMAG, a small island in the sea of Mindoro. N. lat. $11^{\circ} 27'$. E. long. $120^{\circ} 45'$.

MANAMANGALUM, a town of Hindoostan, in Travancore, near the coast of Malabar; 40 miles S.S.E. of Cochin.

MANAMBE, a town on the east coast of Madagascar. S. lat. $15^{\circ} 20'$. E. long. $50^{\circ} 5'$.

MANAMBOTCHE, a town on the east coast of Madagascar. S. lat. $15^{\circ} 50'$. E. long. $50^{\circ} 5'$.

MANAMBOUVE, a river of Madagascar, which runs into the sea on the south coast, S. lat. $25^{\circ} 20'$.

MANAN, an island of the Atlantic ocean, near the coast of Main, in North America; 30 miles in circumference. N. lat. $44^{\circ} 48'$. W. long. $66^{\circ} 45'$.

MANANBATO, a town on the east coast of Madagascar. S. lat. $24^{\circ} 5'$. E. long. $47^{\circ} 30'$.

MANANCIALES, a town of South America, in the government of Buenos Ayres; 190 miles N.N.W. of Buenos Ayres.

MANANGHERA, a river of Madagascar, which runs into the sea on the east side of the island, S. lat. $22^{\circ} 45'$. E. long. $52^{\circ} 4'$.

MANANGOUROU, a river of Madagascar, on the south coast, which runs into the sea, opposite to the island of St. Mary, S. lat. 17° .

MANANZARI, a town on the east coast of Madagascar. S. lat. $21^{\circ} 8'$. E. long. $48^{\circ} 20'$.

MANAPAR, a town of Hindoostan, in the country of Tinevally, lying on a point of land projecting into the gulf of Manera; 33 miles S.E. of Palamcotta. N. lat. $8^{\circ} 18'$. E. long. $78^{\circ} 12'$.

MANARA. See MANAAR.

MANARAN, a small island in the sea of Mindoro. N. lat. $11^{\circ} 20'$. E. long. $120^{\circ} 51'$.

MANARDI, JOHN, in *Biography*, a learned physician, was born at Ferrara in the year 1462. He pursued his studies in philosophy and medicine under that able teacher, Nicholas Leonicens, who was then professor of these sciences at Ferrara, and who took much interest in fostering his talents by private as well as public instruction. But Manardi has been accused of much ingratitude, in his subsequent conduct towards his master. In the year 1482 he was appointed medical professor in his native university, and occupied this post until 1495; when he quitted Ferrara, and resided for some years with Gian-Francesco Pico, of Mirandola, to whom he was both physician and preceptor, and whom he assisted in publishing the work of the celebrated John Pico against judicial astrology. In 1513 he was invited to become physician to Ladislaus, king of Hungary: he accepted the appointment, and remained in that country two years after the death of that prince, which occurred in 1516. On his return to Ferrara, he resumed his functions as a teacher in the beginning of 1519. At an advanced age he married a second wife, young and of great beauty, by which he was supposed to have shortened his days. He died at Ferrara, on the 8th of March 1536, at the age of seventy-four; and a very honourable inscription to his memory was placed on his tomb by his widow. After his return from Hungary, he published the following works, which are all that he produced: 1. "Medicinales Epitolarum Recentiorum Errata et Antiquorum Decreta peritissimè referentes," Ferrar. 1521. This work went through numerous editions, the latter of which were much augmented, to

the number of twenty books, with alterations in the title, viz. "Epitolarum Medicinalium Libri xx." Basil, 1540, folio; to which, and several subsequent editions, were added his "Annotationes et Censuræ in Joannis Mefuæ simplicia et composita;" and ultimately, "Curia Medica xx. Libris Epitolarum, et Consultationum adumbrata," Hanov. 1611, folio. These letters were written principally between the years 1500 and 1536. They contain a miscellaneous collection of remarks, of very various merit, upon the writings and practice of the ancients, with corrections and refutations. Haller terms Manardi a semi-Arabist and semi-Galenist; which implies a bold and observant mind, attached to the ancient doctrines only when they were not repugnant to cautious observation. His censures on the practice of the Arabians are often expressed with great vivacity; but they are mingled with many useless and trivial discussions. He treats of the lues venerea, as a new disease imported from America, and recommends the cure by guaiacum in preference to mercury. 2. He also published "In primum Artis parvæ Galeni Librum Commentarius," Romæ, 1525, 4to. Gen. Biog. Eloy Dict. Hist. De la Med.

MANAS, in *Geography*, a river of Asia, which runs into the Caspian sea, 15 miles N. of Derbend.

MANAS *Hotun*, a town of Thibet; 125 miles N.W. of Tourfan. N. lat. 44° 58'. E. long. 86° 44'.

MANASQUAN, a river of America, in New Jersey, which runs into the Atlantic, N. lat. 40°. W. long. 74° 8'.

MANASSEH, *Half Tribe of*, that lay beyond Jordan, in *Scripture Geography*, was bounded by the tribe of Gad on the south, the Jordan and Semachonite lake on the west, the hills of Bashan and Hermon on the east, and part of the Lebanon on the north. This territory extended from 32° 36' to 33° 36' of latitude, and was more properly called, afterwards, Upper Galilee, or Galilee of the Gentiles. (See GALILEE.) It had several large territories and considerable cities: those of the former fort were known by the names of Gilead, Batanea, Gaulonitis, Auranitis, Machonitis, Geshur, Auran or Amram, and Argob; all of them deriving their names from their capitals. The cities of this half tribe were Bosra or Bozrah, Seficha, Maachah or Maacati, Gershon, Ahtaroth, Adrach or Hadrach-Kedar, or the tents of Kedar, Sueta, Gamala, Esdrai, Gilead, Pella, Abel, Abel-Maachah or Abel-Beth-Maachah, Jabez-Gilead, Corazin or Corozaim, Julias, Bethsaida, near the desert of its name, Girafa or Girgesha, Hippo, Gader, and Ephron, besides a number of others of less note.

MANASSEH, *Half tribe of*, on this side of the Jordan, was situated south of the tribe of Zebulun. The territory of this Manasseh was hemmed in, N. and S., by Issachar and Ephraim, and, on the E. and W., by the Jordan and Mediterranean. It exhibited a variety of plains, mountains, vallies, springs, and a good number of stately cities; among which were Beth-Shean or Scythopolis, Salem, Aner, Bezzech, Abel-Meholah, Castrum Alexandrinum, Tirshah or Terfa, Acrabata, Thebez, Thanac or Tanac, Gath-Rimmon, Maccoth, Ennon, Megiddo, Gilgal, Dor or Dora, Casarea Palestina, and Antipatris.

MANASWARY, in *Geography*, a small island in the Pacific ocean, at the entrance into Dory harbour, near the N. coast of New Guinea. In 1775 captain Forest found the true nut-meg tree on this island.

MANATAWNY CREEK, a river of America, in Pennsylvania, which runs into the Schuylkill, N. lat. 40° 15'. W. long. 75° 40'.

MANATE, a river of Honduras, which runs into the bay, N. lat. 15° 45'. W. long. 88° 22'.

MANATE *Lagoon*, a bay on the coast of Yucatan. N. lat. 18° 22'. W. long. 89° 18'.

MANATEE BAY, a bay on the S. coast of Jamaica. N. lat. 17° 51'. W. long. 76° 45'.

MANATENGHA, a river of Madagascar, which runs into the sea on the E. coast, S. lat. 23° 30'.

MANATI, a town of the island of Cuba, in a bay on the N. coast. N. lat. 24° 32'. W. long. 76° 20'.

MANATI, or *Sea-cow*, in *Zoology*. See TRICHECUS *Manatus*.

MANATI *Lapis*, a name given to a bone, of which there are two found in the head of the manati, or sea-cow; they are roundish, and are usually of the size of a hand-bell. They are said to have great virtues against the stone and gravel, when burnt to ashes, and given in white wine. The world need not, however, regret the scarcity of this remedy, for probably any animal bone, when burnt to ashes, is possessed of all its virtues.

MANATIRSKA, in *Geography*, a town of Russia, in the government of Irkutsk, on the Itchora; 84 miles N.N.E. of Kirensk. N. lat. 58° 45'. E. long. 109° 44'.

MANATOULIN, a chain of islands in lake Huron, extending 90 miles in length, and about six in breadth. The term, according to Carver, signifies in the Indian language the place of spirits, and the island is esteemed sacred by the Indians. N. lat. 45° 20' to 45° 49'. W. long. 81° 50' to 84°.

MANAZERUDAM, a district or province of Turkestan, N. of Fergana.

MANBAGE, a town on the S. coast of the island of Sibiu. N. lat. 10° 10'. E. long. 123° 38'.

MANBALLA, in *Zoology*, the Ceylonese name of a species of serpent, called also the *canine*, or *dog-serpent*, from its manner of flying at every thing that comes in its way, as our dogs do: it is of a deep brown colour, beautifully variegated with white.

MANBED, in *Geography*, a town of Persia, in the province of Irak; 174 miles E.S.E. of Ispahan.

MANBONA, the capital of the kingdom of Sabia, in Africa, situated on the sea coast, at the entrance of the channel of Mozambique; 30 miles S. of Sofala. S. lat. 20° 45'.

MANBOOM, a town of Bengal; 54 miles N.W. of Midnapour. N. lat. 23° 6'. E. long. 87° 28'.

MANBOTE, in our *Old Writers*, a compensation or recompence for homicide, particularly due to the lord for killing his man or vassal.

MANC, in *Geography*, a town of Grand Bucharia; 50 miles W. of Badakshan.

MANCA, a town of America, in West Florida, on the E. bank of the Mississippi, at the mouth of Hona-chitto river.

MANCAENBLANCA, a town of the island of Borneo; 30 miles N. of Negara.

MANCANILLA, in *Botany*, a name given by Plumier to a genus of plants, since characterized by Linnæus in the name of *hippomane*; which see.

MANCENILLA, in *Geography*, a large bay on the N. side of the island of St. Domingo, about 4000 fathoms long from west to east, and 2800 broad from north to south. The S.E. part is very wide, and affords excellent anchorage even for vessels of the largest size. In other parts it is too shallow. The river Massacre, which separated the French and Spanish colonies on the N. side of the island, runs a N. course towards its mouth N.W. and enters the eastern part of the bay. The river swarms with fish, particularly with those large mullets, which are highly prized at Cape François. Fishing in the bay is difficult on account of the drifted wood,

but

but the negroes, being good divers, plunge to the bottom and difengage the feine, in doing which, the negroes, fish, and alligators are engaged in an amufing kind of conteft. The negroes kill the alligators, knock out their teeth, and fell them for making corals, which ferve to mark the luxury and pride of thofe who fufpend them to the necks of their children. The plenty of fifh often attracts fhips of war to this bay. The mouth of Maffacre river lies in N. lat. 19° 44'. W. long. from Paris 74° 9'.

MANCHA, LA, an extenfive province of Spain, north of New Caftile, by which it is bounded on one fide, on the W. by Eftremadura, on the S. by Cordova and Jaen, and on the E. by Murcia and Valencia. It is 43 leagues long and 33 broad; and divided into Upper and Lower. The capital of the former is Ciudad Real, and that of the latter Occana. The foil is in general dry and dufty; and the country abounds in plains of confiderable extent, but they are wafte and almoft wholly without trees. The rivers that water it are little more than rivulets. A great part of the province is furrounded by mountains, forming part of the chain beginning in Sierra d'Occa, called by the ancients "Montes Orofpadani." The moft confiderable of thefe mountains is the Sierra d'Alcarrez, extending from N. to S., towards the fouthern and eaftern parts of the kingdom of Jaen. In La Mancha alfo, near Alcarrez, and at the fide of the Sierra of that name, begins the famous Sierra Morena, or the "Montes Mariani" of the Romans. They continue to the kingdom of Cordova; a ridge fpreads into Jaen, and they extend as far as Eftremadura, and even to the banks of the Guadalquivir. The province of La Mancha contains 111 parifhes, 78 monafteries and convents, two cities, and 121 towns, of which ten belong to the crown, and 75 to the military orders, 46 villages, one intendency of a province, and one hofpital. The principal towns are Ciudad Real, Occana, Alcafar, and Almagro.

Ciudad Real, which is reckoned the capital of La Mancha, is fituated in a plain, which is rich, and productive of corn, wine, and fruits. This city has loft much of its ancient fplendour; its woollen manufactures and trade have much declined, and its population is of courfe reduced to the number of eight or nine thousand perfons. The town is regularly laid out; the ftreets are ftraight and well paved; and it has a fquare 150 paces long, and 75 broad, furrounded with two rows of boxes for the accommodation of the fpectators at bull-fights and public fhow. This place is the refidence of the intendent of La Mancha, and the grand vicar and ordinary of the archbifhop of Toledo, and the principal place within the controul of a corregidor. In the parifh church of St. Mary is a fpacious and lofty chancel; the chief altar of which is compofed of four different orders of architecture, each of which is ornamented with pillars, upon the whole well executed. A great quantity of leather for fhoes was formerly prepared in this city, and a confiderable manufactory of them was eftablifhed. The cardinal of Lorenzana, the archbifhop of Toledo, erected at his own expence a hofpital, which coft about 12,500*l.* fterling; and he alfo fet on foot a manufactory of flannels and coarfe woollen cloths; and he lately propofed to eftablifh another of filks. For an account of the other towns, fee the refpective articles. The population is rather more than 200,000 inhabitants, or, according to the furvey of 1787 and 1788, 206,160; and the clergy not numerous. The Mefa d'Occana is the richeft and moft fertile plain in the whole country.

La Mancha is a flat level country, and the foil is parched with heat. The productions of fuch a foil muft neceffarily be limited; it produces corn, and efpecially oats, in fuffi-

ent quantity to fupply the neighbouring provinces. But the principal part of the country is fo deftitute of trees, that for feveral leagues in fucceffion you fcarcely fee one. The moft common trees are chefnuts of a dwarf fpecies, which grow fpontaneoufly; olive trees, however, are found in many parts, and alfo a number of vines, the beft of which are thofe of *Menzanares*, which fee. The other productions of La Mancha are faffron, honey, and fpar. No fruit is to be met with except in fome particular diftricts, and in fmall quantities. Almagro is famous for melons and potatoes. The meadows are not numerous, except for about four leagues between Ciudad Real, and Santa Cruz de Mudela, where they are fine and extenfive; immense herds are fed in thefe plains, and efpecially mules, which are of an excellent breed. The manufactures of La Mancha are now declined. They formerly fabricated ribbons, garters, worfted flockings, tapeftry, and filks of different forts, and a great quantity of leather-gloves, both at Ciudad Real and Occana: at the former of thofe towns they made all forts of woollen ftuffs, but they have very much declined. A fabric of blond lace has been lately fet on foot at Almagro, which employs 2300 people. The other branches of labour are reduced to four; one of hard foap at Occana; another of flannels at the fame place and Campo de Criptance; a third at Alcazar de St. Juan, of gunpowder; and three refining-houfes of faltpetre at Pedronera, Zemblaque, and Alcazar de St. Juan, the laft of which furnifhes annually 200,000 quintals of faltpetre to the crown, on whose account it is wrought. The wool fpinning is a confiderable fource of induftry throughout this province, and employs from 12 to 16,000 people of, all ages and fexes. Commerce is in a very low ftate in this province: the only productions with which it furnifhes the neighbouring provinces are a little fpar, oats, and wine, together with a fmall quantity of blond lace and fhoel-leather. But thefe few articles do not counterbalance the imports from other provinces and countries, which fupply La Mancha with fhot, fpices, falt provifions, hardware, linen, muffins, broad cloth, fine woollen ftuffs, filks, and in a word all articles of luxury, and even many of neceffity with regard to clothing. The animal and vegetable kingdoms prefent nothing worthy of much attention in this province: but it has fome mines and mineral waters that may deferve notice: fuch are mines of iron, ochre, rock-cryftal, bole, calamine, antimony, cinnabar, &c. It has alfo mineral waters both for drinking and bathing. In the cultivation of the arts and fciences, La Mancha does not excel. The manners of this province differ little from thofe of Caftile. The people, fays La Borde, are more grave and folemn in their deportment, and more attached to ancient cuftoms and ceremonies, and their conftitutions more robuft and fit for labour: their temper in general is mild and peaceable, and they are truly good-humoured. Perfons in the higher ranks pafs their lives in eafe and apathy; on the other hand, the common people are laborious and frugal; and both orders, fays La Borde, take no part in any fort of diffipation, or even of diversion. Every thing is grave and formal. Other travellers, however, report, that this is the moft cheerful country in Spain; that the inhabitants are very fond of mufic and dancing. A player on the guitar, and a finger of fequidillas, are perfons in great requit in this part of the country. The girls, young men, and married women are faid to afemble at the firft found of the intrument; the beft voices fing fequidillas, and the blind accompany them on their intruments. A late traveller fays, "there is no labourer nor young female peafant who is not well acquainted with Don Quixote and Sancho." The traveller, fays another writer, can fcarcely en-

ter the province of La Mancha without having constantly in his thoughts the fabulous hero, whose name renders this country more celebrated than its spacious and parched-up plains could ever have made it. Cervantes, in his endeavours to ridicule the taste for romances, perhaps has left only a fonder recollection of the spirit of chivalry, which his hero, notwithstanding his madness, always renders venerable. The names of Quixote and Tobofo are impressed on the memory of every one, and one looks round for the village of the famed and peerless Dulcinea, and the wood where the first meeting took place between her and the doughty Don Quixote. The costume of all ranks of the people, in the principal towns of this district, is similar to that of New Castile. The peasant wears a close camifole of cloth, or leather, fastened with a leathern girdle, and on his head a square cap rising to a point. The sides, which are turned up, continually beat against each other: it is made of cloth, or leather, and is called a "montera." A stranger, who visited some of the assemblies of amusement in this province, would be astonished at seeing a labourer in the dress of Sancho, wearing a broad leathern girdle, become an agreeable dancer, and perform all his steps with grace, precision, and measure. The songs and seguidillas on these occasions are peculiar to this part of the kingdom, and it is to be remarked, that to singing and dancing the Manchegas add the merit of poetry. Most of the seguidillas are voluptuous, and turn on the subject of love or absence; though some are satirical.

MANCHAC, a town or parish on both sides of the Mississippi, in Louisiana, extending 12 miles on the river. See **LOUISIANA**.

MANCHE, LA, the *Channel*, one of the nine departments of the N.W. region of France, composed of Cotentin and Avranchin, and opposite to Jersey and Guernsey, in 49° N. lat. The five circles into which it is divided are Valognes, containing 143,777 inhabitants, St. Lo, including 90,329, Mortain 69,565, Avranches, 94,711, and Coutances, 130,530. The soil, partly sandy and partly marshy, is better adapted to pasture than cultivation: it produces, however, some grain, flax, hemp, fruits, and roots. It has mines of copper, iron, and cinnabar, with mineral springs. Salt, in considerable quantities, is manufactured and exported. For a further account of this department, see **CHANNEL**.

MANCHESTER, a market town in the hundred of Salford and county of Lancaster, England, is seated on the banks of the small rivers Irk, Medlock, and Irwell, at the distance of 185 miles from London and 32 from Liverpool. In point of commercial and political importance, though not a corporation, it is undoubtedly the second town in the kingdom. The whole population, according to the parliamentary census of 1800, amounted to 84,053 persons, of whom 44,500 were engaged in different branches of trade: 44,900 were females, and 39,110 were males. The amazing increase of population in this town is shewn by returns obtained in the years 1773 and 1811. In the former year there were 29,951 persons; and in the latter 98,573. The parish of Manchester comprehends several of the contiguous townships, the whole population of which is 136,370.

Manchester appears, from the testimony of Mr. Whitaker, to be a town of great antiquity. A station occupied by the ancient Britons is supposed to have been settled here 500 years before the Christian era. It did not, however, deserve the name of a town till after the invasion of this island by the Romans, when it became one of the fortified retreats of the brave but undisciplined natives. At this period it was

called Mancenion, that is, the "place of tents;" but Agricola, who conquered it A.D. 79, changed its name to Mancunium. It was afterwards called Manduefuedum, and Mancastre, from which latter term its present appellation is evidently derived. The Romans, upon achieving the conquest of this station, built an extensive castle upon the spot now denominated Cattle-field, situated near the conflux of the Medlock with the Irwell; but every vestige of this is removed to make room for modern buildings. After having retained it in continued possession for somewhat more than 400 years, the declining fortunes of Rome compelled the legionary soldiers to abandon it to the original possessors, who in their turn soon yielded it to their new conquerors and tyrants the Saxons. During the dynasties of that ferocious people, Manchester was several times a place of military conflict, being seated on the immediate confines of the Northumbrian kingdom. Edward the Elder, king of the Mercians, is said to have fortified and rebuilt a considerable part of it, which time and violence had united to destroy. At the period of the grand Domesday survey, two churches appear to have existed here, called St. Mary's and St. Michael's. Albert de Gresley obtained from the Conqueror the lordship of the manor. In 1201 his grandson, Thomas, granted a charter to his burghesses of Manchester, constituting their town a free borough. Lord de la Warr, the last male heir of this family, laid the foundation of the collegiate church, which tended, in no small degree, to promote its increase and improvement. This town in early times was a place of sanctuary, and one of the eight places to which that privilege was confirmed by Henry VIII. in 1540. The year following, however, it was removed to Chester, which the statute declares "had a strong gaol and a mayor, and had not the wealth, credit, great occupings and good order which Manchester had." In 1605, a pestilence raged here, and carried off upwards of 1000 persons. Upon the breaking out of the civil war between Charles I. and the parliament, Manchester decidedly espoused the republican cause, and successfully resisted several sieges by the royal army, under the earl of Derby. Notwithstanding these circumstances, however, the inhabitants seem to have honoured the restoration of Charles II. with particular marks of joy.

From this short sketch it will readily be perceived that, in an historical point of view, Manchester is only entitled to a very small share of general attention: though regarded as a manufacturing town, it is deservedly distinguished above every other in England. When it first began to be noted for its manufactures is uncertain; but in the time of Edward VI. Manchester cottons, Manchester rugs, and Manchester friezes are frequently mentioned in various acts of parliament. In 1650, its trade is described as "not inferior to that of many cities in the kingdom, chiefly consisting in woollen friezes, fustians, sack-cloths, mingled stuffs, caps, inkles, tapes, points, &c. whereby not only the better sort of men are employed, but also the very children by their own labour can maintain themselves. There are, besides, all kinds of foreign merchandize brought and returned by the merchants of the town, amounting to the sum of many thousand pounds." About this time great quantities of linen yarn seem to have been imported here from Ireland, which being wrought into cloth, was re shipped for the Irish market. It was not, however, till after the middle of the last century, that Manchester rose to a pre-eminent rank among our manufacturing towns; a rank for which it is chiefly indebted to the ingenuity and invention of Mr. Hargreave and sir Richard Arkwright. Previous to the year 1760, all the cotton yarn manufactured in the country was spun by hand, upon that well known domestic instrument called

MANCHESTER.

called a one-thread wheel. Shortly after this period, Mr. Hargreave constructed a machine denominated a *jenny*, by which one person was enabled to spin from twenty to forty threads at a time. These machines soon came into general use, but were much limited in their employment till the year 1775, when sir Richard brought the improvements of his predecessor to much greater perfection. This gentleman having established his extensive manufactories here, made Manchester the principal seat of the spinning trade, the rapid increase of which produced a corresponding increase in the buildings and population of the town. See the preceding articles of ARKWRIGHT, vol. ii. and COTTON, vol. x. for further particulars. In Brayley's "Beauties of England," vol. iii., Derbyshire, is an interesting and ample memoir of sir Richard Arkwright, with accounts of the present state and processes of the cotton manufactures.

As Manchester, notwithstanding its extent and political importance, is not a corporate town, the government is vested in a headborough, called the boroughreeve, and two constables. These are chosen annually from the most respectable of the inhabitants by a jury impanelled by the steward of the manor, at the courts leet, which are held by the lord of the manor twice every year at Easter and Michaelmas. The boroughreeve is usually one of the gentlemen who has served as constable for the preceding year, and is treated perhaps with more respect (the paraphernalia of a mace-bearer excepted), than any mayor in the kingdom. The chief duty of this officer is to preside at public meetings, and to distribute certain charities, denominated "boroughreeve charities," all the judicial functions connected with the police being executed by the constables and their deputies. A court of requests is held every month for the recovery of small debts; and every Wednesday and Saturday several respectable magistrates sit in the court-room of the New-Bayley for the administration of justice in pleas of almost every description, whether civil or criminal. Quarter sessions also are held four times a-year; and, from press of business, the court is sometimes obliged to continue its sittings for nearly a fortnight.

This town is divided into two portions by the river Irwell, which receives the Irk at a short distance from the collegiate church. The situation of Salford is very similar to that of Southwark, the communication between the two towns being kept up, as in London, by three bridges thrown across the river at different places. The most ancient of these is called the "Hanging bridge," Old, or Salford bridge, and is supposed to have been originally founded in the time of the Romans. The present, built in the reign of Edward III., was formerly very dangerous for foot passengers, but in 1778 it underwent a thorough repair and extension. Blackfriar's bridge, erected about fifty years ago, is constructed entirely of wood, and flagged for foot passengers only. But the finest bridge over the Irwell is the New bridge, commonly called the New Bayley bridge, which was founded in 1785, and is constructed wholly of stone. It consists of three large arches, and a fourth of smaller dimensions, left open in support of the duke of Bridgewater's right to a towing path to his quay, in Salford, agreeably to the tenor of the act, enabling His Grace to form his extensive canals. Six bridges are here thrown across the Irk, the chief of which are Huntsbank bridge, situated near the college, and Scotland bridge: nine are thrown over the Medlock, which runs in a serpentine course through the southern suburbs of the town. Oxford-street bridge forms a part of a street of that name. A variety of other bridges lie across the numerous canals which intersect the suburbs at different places, and at Knotmill, in the vicinity of Cattle-field, is a

very noble tunnel, through which the Rochdale canal passes, not far from its junction with that of the late duke of Bridgewater's.

With respect to the plan and buildings of this town, it may be remarked, that the portion of it called the Old Town consists of a very motley assemblage of old and new houses, closely huddled together, and exhibiting little elegance in their exterior appearance. Even the new streets, though much superior to the old, are usually narrow, except in a few instances where they have been improved by the acts of 1775 and 1791. In these latter, however, there are a number of very excellent modern buildings. Mosley-street and Portland place would do honour to the capital itself. Grosvenor-square, when finished, will probably rival the finest in the kingdom. The suburbs of Ardwick-green and Salford crescent are peculiarly pleasant, and contain some handsome houses, which are mostly occupied by the wealthy manufacturers.

The churches and other public edifices of this town are numerous, but few of them are distinguished for architectural beauty. The College, or parish church, founded, as already mentioned, by lord de la Warr, bishop of Durham and rector of Manchester, is a venerable building in the rich ornamented style of the 15th century. In the interior its appearance is confused and heterogeneous. The windows still retain many rich remains of the painted glass with which they were formerly ornamented. The roof is of elegant wood-work, interperfed with carved figures of angels playing upon different musical instruments. In front of the gallery, on each side of the clock, are suspended the colours of the 72d regiment, raised in this town by subscription during the American war, whose noble conduct at the siege of Gibraltar is still remembered with exultation by every lover of his country, and particularly by the inhabitants of Manchester. Adjoining to this church are a number of small chapels well worthy of the attention both of the architect and the antiquary. A view of this church, with a particular account of its history and architectural peculiarities, written by J. H. Markland, F. S. A. are given in the third volume of "The Architectural Antiquities of Great Britain."

St. Ann's church, situated at the end of the square to which it gives name, is distinguished for its handsome appearance. It was founded by lady Ann Bland in 1709, in compliment to whom it was dedicated to the saint whose name it bears. The church of St. Mary, situated between Dean'sgate and the river Irwell, is admired for the beauty and fine proportions of its spire, which measures 186 feet in height. The lantern which supports it is peculiarly striking, being composed of eight noble Ionic pillars, surmounted by a large globe, upon which is placed a massy cross. St. John's church is built in the style which is called modern Gothic. In the vestry are several pictures, and a beautiful window of stained glass. Two of the windows in the body of the church are also decorated with fine painted glass. The other churches in this town are St. Paul's in Turner-street, St. James's in George-street, St. Michael's in Angel-street, St. Clement's in Lever-street, St. Stephen's near Bolton-street, St. George's in the neighbourhood of Newton-lane, and St. Peter's, which terminates the prospect down Dawson-street and Mosley-street. The latter was designed and executed by James Wyatt, esq. In Salford is Trinity chapel, a neat stone edifice of the Doric order.

Besides these churches there are three others also belonging to the establishment, situated in the adjoining townships of Ardwick, Chorlton, and Pendleton, which, from their vicinity to Manchester, may not improperly be considered as belonging to it. Numerous chapels and meeting-houses, appropriated for the public worship of dissenters of almost every denomination

MANCHESTER.

denomination, are likewise dispersed through various parts of the town. Catholics are numerous here, and the Methodists are found to comprise a very considerable proportion of the whole population.

The vast number of excellent charitable institutions with which Manchester abounds are highly creditable to the benevolence, liberality, and public spirit of its inhabitants. Indeed, in this respect, this town is not surpassed by any in the British empire, whether the suitableness of the buildings for their respective purposes, or the liberal contributions by which they are supported, are taken into view. Among these establishments, Chetham's-Hospital, commonly called the College, is first deserving of notice, by priority of foundation. It owes its existence and entire support to the munificent bequest of Humphrey Chetham, esq. of Clayton, whose will is dated the 16th of December 1651. At first, the number of boys clothed and educated here amounted only to forty; but from an increase in the value of the estates belonging to the foundation, the number was augmented more than thirty years ago to eighty. The building appropriated to this charity is situated on a lofty rock, near the confluence of the rivers Irk and Irwell, immediately adjoining to the collegiate church already mentioned, to which indeed it formerly belonged. Upon this spot Mr. Whitaker supposes the Romans had their prætorium, or summer camp; and certainly the situation was admirably adapted for that object. In a large gallery, in this edifice, is a public library, likewise founded by Mr. Chetham, which now contains upwards of 15,000 volumes in various languages, and in almost every branch of science or literature, besides some very valuable manuscripts. The Infirmary, Dispensary, Lunatic Hospital, and Asylum, are all included in one spacious building, situated in the front of Lever's Row, which is considered as the highest ground in the town. The foundation of the first edifice was laid in 1753, for the reception of forty patients; but the number was soon afterwards doubled, and now there are 160 beds appropriated for the use of the sick. The Lunatic Hospital was opened in 1766, and the Dispensary in 1792. The annual subscriptions for the support of these institutions, amount to several thousand pounds. Here are two poor-houses, one of which was erected in 1792, on the side of the Irk, nearly opposite the College; and the other built the year following, at the upper end of Greengate in Salford. Both of them are handsome buildings, and admirably fitted up for the purpose to which they are appropriated. The Lying-in-Hospital was instituted in 1790, and not only provides professional aid for in-door patients, but likewise for the assistance of such poor married women as find it inconvenient to leave their own houses. The House of Recovery is intended chiefly for the reception of patients afflicted with contagious fevers. The other principal charities are the strangers-friend-society, instituted in 1791, and the boroughreeve's charity: the former designed for the relief of strangers, and the latter for the aid of the poor inhabitants in general. The Free-school is an excellent foundation, which owes its origin to Hugh Oldham, bishop of Exeter. In this school the greater part of the clergy of the town and neighbourhood have been educated, as well as many noblemen. There are, besides, several inferior charity and Sunday schools in various parts of Manchester.

Though in every respect a manufacturing town, Manchester has not wholly neglected the promotion of literature and science. Societies, having this object in view, are numerous. The chief of them are the Literary and Philosophical, instituted by Dr. Thomas Percival in 1781; and the Philological Society, which commenced its meetings in 1803. Here are also two very extensive public

circulating libraries; the former founded in 1757, and the latter in 1792. The Manchester Agricultural Society was established in 1767, and has for its object the encouragement of the useful arts in general, by the distribution of premiums for scientific discoveries. A laudable practice is also adopted, of granting premiums to cottagers, who support their families without parochial aid; and in some instances likewise, honest and good servants are rewarded by honorary presents. The repository, designed to encourage and reward industrious females, has proved highly serviceable to many individuals, and is therefore justly entitled to liberal and careful support.

Besides those already noticed, many other public buildings and institutions, intended either for useful purposes or for amusement, may properly claim attention in this place. The Theatre, a commodious and extensive building, was erected in 1807. It is open during seven months of the year, and can in general boast of a very respectable company of performers. The gentlemen's Concert-room is elegant and capacious, and will accommodate upwards of 1200 persons. This is supported by a voluntary subscription; and strangers are admitted with a subscriber's ticket. There are likewise very excellent new and commodious assembly-rooms for balls, card-assemblies, &c. The New-Bayley, or Penitentiary house, is well deserving attention, both on account of the extent of the edifice and arrangement of its parts, and also for the economy observed in the interior. Immediately above the entrance is a large room, where the sessions are held; and adjoining to it are several commodious rooms for the magistrates, jurors, &c. Beyond this, in the centre of a large area enclosed by lofty walls, stands the prison, an extensive building in the shape of 2 crosses, three stories high. It is remarkable for the cleanliness with which it is kept, as well as for its regulations. Prisoners, not confined for capital crimes, are allowed the free exercise of their respective trades. A workhouse, on a large scale, has also been lately built.

A new structure, called the Manchester Commercial Building, or Exchange, was commenced in the year 1806, from designs by Mr. Harrison, architect. It was completed in January 1809, and is appropriated to the use of the merchants and manufacturers of the town, who subscribed certain shares of 50*l.* each, to defray the expences of its erection. The building comprises an exchange-room, dining-room, drawing-room, ware-rooms, shops, and counting-houses, a suite of rooms for the post-office, with extensive cellars under the whole. It is built of stone, and presents a simple, but classical façade, with demi-columns of the Grecian Doric order. The exchange-room is very spacious, containing an area of 4000 superficial feet, in the centre of which is a glazed dome, 40 feet in height, supported by eight fluted columns of the Ionic order. Over a part of this room is a gallery, or semicircular suite of rooms, appropriated to an extensive library, belonging to Mr. Ford, a respectable bookseller of this town, whose large catalogue contains a valuable assortment of scarce, curious, and interesting works.

The Trade of Manchester consists chiefly, but not entirely, in the manufacture of cotton goods. Velvets, checks, a variety of small articles, such as filleting, tapes, laces, gartering, &c. are likewise made in great quantities. The silk manufacture has advanced rapidly here within the last ten years; and a manufactory for making and finishing hats is now carried on to a great extent. The profusion of goods made here is conveyed, by means of the Irwell and the numerous canals which intersect the town, to different ports both on the eastern and western coast. Liverpool, however, is the principal mart for the exportation of the cottons; and between

between that town and Manchester there is a constant and rapid communication both by land and water-carriage.

Manchester has two markets, called the old and the new, both of which are held twice a week on Tuesdays and Saturdays: the latter is the principal one for provisions; the former being mostly frequented for transacting the manufacturing business of the town with the country traders. Most of the streets are paved and lighted, and are guarded at night by about 200 watchmen. For the regulation of parochial affairs, Manchester is divided into fourteen districts. It gives title of duke to the noble family of Montague, some of whom have been distinguished characters. In the paths of literary fame, however, it can claim little distinction; but Byrom and Falkner may be properly ranked with what Fuller calls "the worthies of the place."

The environs of this town abound with old mansions, respectable villas, and a number of modern seats. Ancoats-hall, the manorial mansion-house, is a venerable building, the parts of which are disposed in a most curious and grotesque manner. Hulme-hall, or Holme, is an edifice of a similar kind, exhibiting a remarkable specimen of ancient domestic architecture. It stands on the edge of a shelving bank of the Irwell, and exteriorly offers to the view a most romantic and picturesque object. Heaton-house, the seat of the earl of Wilton, lies about four miles to the north-east of the town. The house, a handsome modern structure of stone, stands on a commanding situation, in the midst of a very noble park, finely decorated with venerable trees and numerous thriving plantations. The other principal seats are Trafford-house, Alkington, and Smedley-hall; near which last is Broughton-hall, formerly the property of the Stanleys, earls of Derby. Every part of the surrounding country displays the highest state of agricultural improvement, and in times of prosperity presents one vast scene of enterprize and industry. Beauties of England and Wales, vol. ix. Aikin's History of Manchester, and its Environs, 4to. by J. Aston. The Manchester Guide, 12mo. 1804. Whitaker's History of Manchester, 2 vols. 4to. 1771.

MANCHESTER, a port and fishing town of America, on the sea-coast between Cape Anne and Beverly, in the county of Essex and state of Massachusetts. This township was incorporated in 1645 and contains 1082 inhabitants.—Also, a port-town of Vermont, in Bennington county, on Battenkill; 22 miles N.E. of Bennington and 59 N.E. of Albany in New York; the township containing 1397 inhabitants.—Also, a township in York county, Pennsylvania, including 1175 inhabitants. West Manchester, in the same county, contains 794 inhabitants.—Also, a small port-town of Virginia, on the S. side of James river, opposite to Richmond, with which it is connected by a bridge.—Also, a town of Nova Scotia, 10 leagues N.W. of Cape Canso, which in 1783 contained 250 families.

MANCHESTER HOUSE, a factory belonging to the Hudson Bay Company, 100 miles W. of Hudson's house and 75 S.E. of Buckingham house; situated on the S.W. side of Saskatchewan river, in the N.W. part of North America. N. lat. 53° 14' 18". W. long. 109° 20'.—Also, a port-town in Adam's county, on the N. bank of the Ohio, about 10 miles above Massieburgh; incorporated in January 1802.

MANCHICOURT, PIERRE, in *Biography*, a native of Behune, in Artois, and director of the music in the cathedral of Dornick, who flourished in the middle of the sixteenth century, and whose name frequently appears among the composers of motets and songs, in four and five parts,

VOL. XXII.

does not reward lovers of music of this period for the trouble of scoring his productions so much as many of his contemporaries; and, indeed, in three or four of them that we have examined, he seems not only a dry but a clumsy contrapuntist.

MANCHINEAL HARBOUR, in *Geography*, a bay on the E. coast of Jamaica. N. lat. 18° 4'. W. long. 75° 58'.

MANCHINEAL, in *Botany*. See HIPPOMANE.

Dr. Peyssonnel, in his observations on the fruit of this tree, informs us that the savages use the juice of it to poison their arms, the wounds of which are thereby rendered mortal; that the rain which washes off the leaves, and falls on the human body, causes blisters to rise like boiling oil, and that even the shade of the tree is fatal to those who sit under it. However, timely application by purges and emetics have prevented their ill effects. Phil. Trans. vol. I. art. 105. p. 772.

MANCHULL, in *Geography*, a town of Hindoostan, in the circar of Joodpour; 19 miles S. of Joodpour.

MANCIAT, a town of France, in the department of the Gers; 16 miles S.W. of Condom. N. lat. 43° 39'. E. long. 0° 7'.

MANCINELLA, in *Botany*. See HIPPOMANE.

MANCINI, FRANCESCO, in *Biography*, composed an oratorio which acquired him great reputation, intitled "L'Amor divino trionfante nella morte di Cristo;" and hymns for the Florentine brotherhood of the Pietà, during Lent, which were published at Rome in 1700. Mancini was a Neapolitan, and, seemingly, the first opera composer of eminence in that country during the last century. Between the years 1700 and 1731, he produced several operas and intermezzi that were much esteemed by the first professors of his time, particularly Hasse and Geminiani, who always spoke of him as a very able master. The celebrated opera of *Idaspe fidele*, or *Hydaspe*, brought on our stage in 1711 by Nicolini, was set by Francesco Mancini. In this opera it was, that Nicolini's battle with the lion gave birth to Addison's humorous papers on the subject, in the first volume of the Spectator.

MANCINI, THOMAS, son of the chapel-master of Groningen, and one of the 53 examiners of the organ erected in that city in 1596, recorded by Werckmeister, in his "Org. Gruning. Rediv." See ORGAN, and WERCKMEISTER.

MANCINI, GIAMBATISTA, maestro di canto della corte Imperiale, or singing-master to the Imperial court, and Accademico filarmonico, published in 1774, at Vienna, a treatise on singing in 4to. intitled "Pensieri e Riflessioni pratiche," or practical thoughts and reflexions on figurative song; a work of merit, superior to any treatise on the same subject that has appeared since the time of Tosi. The author was a scholar of the famous Bernacchi, the celebrated disciple of Pistocchi, the founder of the Bologna school of singing, and master, not only of Mancini, but of Amadori, Guarducci and Raof, the celebrated tenor, all renowned opera singers of the first class during the last century.

In the II^d article, or section of this book, the author gives a list and character of all the most celebrated opera singers, male and female, from the time of Pistocchi down to Pacchieratti and the Gabricle.

In the III^d section he describes the vocal organ, its several parts, physical defects, and qualities necessary to its perfection.

IV. Of the *voce di petto*, voice from the chest; *voce di*
3 C *testa,*

test, or falset, and the art of uniting them, that is, the natural voice that comes from the chest, and the feigned voice that is merely formed in the throat, and the uniting them in such a manner, that the hearer cannot distinguish where nature ends and art begins.

V. Of intonation.

VI. Of the manner of opening the mouth, and emission of voice free from the teeth, nose, and throat.

VII. Of the portamento, and manner of forming, modulating, and conducting the voice.

VIII. Of the union of different registers of voice, of the *apoggiatura* and concealment of defects.

IX. Of the *mezza di voce*, or swell, and description of the voice of Farinelli.

X. Of the shake and beat. The author calls the trill or shake the support, ornament, and life of song; "Oh trillo! sostegno, decoro, e vita del canto." Describes the shake *alla capro*, *alla cavallo*, or that resembles the goat's cough, or the neighing of a horse.

XI. Of the cadence or close.

XII. Of agility of voice or rapid execution.

XIII. Of the knowledge and accomplishments necessary to appearing on the stage as a public singer.

XIV. Of recitative and action.

XV. Of the sobriety and regularity of conduct necessary to a student in singing.

The author in conversation mentioned to us at Vienna, what he has since inserted in his book, a curious operation performed at Naples by signior Francisco Piccillo, an eminent surgeon, on the organ of voice, by cutting the glands of the throat, when so inflated or prominent as to obstruct the free passage of the voice. It is certain, says signior Mancini, that the glands of the throat may be safely removed, but it is likewise equally certain that the defect still remains. The operation was performed at Naples on three several persons in a most dextrous manner, with two cane-knives, without however meliorating the voice.

The ingenious author of this useful tract, who had himself been a capital vocal performer on the opera stage, and drew his rules from long practice and experience, died at Vienna about 1779. A third edition of the "Penfieri e Relfione," and Mancini's "Treatise on Singing," appeared at Milan in 1778.

MANCIPIUM, or MANCEPS, in the language of ancient jurisprudence, was a name used to distinguish those spoils that were taken with the hand; and whenever they were sold or *emancipated*, the purchaser required some assurance that they had been the property of an enemy, and not of a fellow-citizen.

MANCIPILE, MANCEPS, in *Old Authors*, denotes a carter. There was anciently an officer in the Temple called by this name, who is now called the steward; and both name and office are still retained in the colleges in both universities.

MANCO CAPAC, in *Biography*, legislator and first Inca among the Peruvians, was the twelfth in ascent from the Inca who reigned at the time of the Spanish invasion of Peru in 1532, which interval was computed by the natives at about 400 years. According to their tradition this personage, with his wife and sister Mama Ocollo, otherwise called Caya Mama, both of majestic form and clothed in decent garments, appeared in an island of the lake Titicaca, and declared themselves to be children of the sun, sent to civilize and instruct the savage people who then inhabited that country. Manco accordingly instructed the men in agriculture and other useful arts, while his wife taught the

women to spin and weave. After this, Manco began to form them into a regular society, and to give them a system of laws and policy. Manco Capac, toward the close of a long and prosperous reign, assembled his numerous family and principal subjects in the city of Cuzco, and after a suitable exhortation he expired in their sight. His memory was held in the utmost veneration by his own people, and as far as we can rely upon the tradition annexed to his name, he seems justly entitled to rank among the benefactors of mankind. If what is supernatural be rejected from this tradition, it will appear that some stranger from a civilized land arrived in Peru, and, by calling in the aid of religion, obtained an ascendancy over the minds of the natives, which enabled him to form a regular government, and place himself at its head. Absolute power in the monarch was the necessary consequence of this sanctity of character, and the government took the form of a theocracy. Its civil institutions were directed to the preservation of order and tranquillity; its religious rites were for the most part innocent and humane; and gentleness and submission distinguished the Peruvians among the nations of South America. Robertson's Hist. of America.

MANCORA, in *Geography*, a town of Peru, in the diocese of Truxillo, on the road from Guayaquil to Truxillo, on the sea-coast; 70 miles N. of Payta.

MANCORON, a word used by the ancients to express what they call a sort of honey, which seems to have been evidently our modern *fugar*. They say that it was a sort of dry honey found concreted in canes or reeds, and was of the consistence of salt, and that it was found in India and Arabia Felix, and that when taken into the mouth, it broke under the teeth like salt.

MANCUNIUM, in *Ancient Geography*, a town of Britain mentioned in the 10th Iter or rout of Antonine's Itinerary, and supposed to be the same with *Manchester*; which see.

MANCUS, formed of *manu cufus*, in *Antiquity*, an Anglo-Saxon gold coin, equal in value to 2½ solidi, or thirty pence; and in weight to fifty-five troy grains. The first account of this coin that occurs in the history of our country, is about the close of the eighth century, in an embassy of Cenwulf, king of Mercia, to Leo III. requesting the restoration of the jurisdiction of the see of Canterbury; this embassy was enforced by a present of 120 mancuses. Ethelwolf also sent yearly to Rome 300 mancuses: and these coins are said to have continued, in some form or other, till towards the conclusion of the Saxon government. The heriots of the nobility are chiefly estimated by this standard in Canute's laws. It came originally from Italy, where it was called ducat: and is supposed to have been the same with the drachma or miliarenfis, current in the Byzantine empire. Clarke on Coins, p. 280, &c. See MARK.

MANDA, in *Geography*, an island in the straits of Malacca, near the coast of Sumatra, about 35 miles in circumference. N. lat. 0° 28'. E. long. 103° 2'.

MANDACH, a village in the district of Wildenstein, in the Swiss canton of Aargau, on the left banks of the river Aar. The neighbourhood of this place is famous for the variety of petrifications with which it abounds. The fields in its vicinity furnish numerous fragments of immense cornua ammonis, most of them several feet in diameter, likewise large quantities of petrified coralloids, such as millepora, porpyta, trochita, terebratulita. Not far from Mandach, at Holwyl, elephants' tusks have been found, together with various species of cochlita, buccinita, turbinita, ostracita, echinita, &c. Still more of these fossil remains occur at

Deutsch-

Deutsch-Beuren, among which is a vast stratum of gryphitæ, the prototypes of which do no longer exist; and, in a bed of sand, a thin stratum of the shell called *concha hypococephaloides* in its recent state, and hitherto not observed in any other place. Near Elfingen a stratum of small *cochlitæ* is seen, perfectly unmingled with other substances. In the neighbourhood of Veltheim we find *belemnites*, *ammonites*, *tellinitæ*, &c. in great profusion; and at Castelen and Schenkenberg, *oolites*, *ostracitæ*, *chamitæ*, &c.

All these petrifications in the district of Wildenstein are deposited in the sand-stone formation, which overlays strata of lime-stone.

MANDADO, a small island in the East Indian sea, near the N. coast of Celebes. N. lat. $1^{\circ} 18'$. E. long. $124^{\circ} 21'$.

MANDAL, a sea-port town of Norway, in the province of Christianland, at the mouth of a river of the same name; 19 miles W.S.W. of Christianland. N. lat. $58^{\circ} 2'$. E. long. $7^{\circ} 42'$.

MANDALIG ISLANDS, three or four small islands near the N. coast of Java. S. lat. $6^{\circ} 27'$. E. long. $110^{\circ} 56'$.

MANDAMUS, in *Law*, a writ issuing out of the court of king's bench, sent by the king, and directed to any person, corporation, or inferior court of judicature within the king's dominions; requiring them to do some particular thing therein specified, which pertains to their office and duty, and which the court of king's bench has previously determined, or, at least, supposes to be consonant to right and justice. This is a high prerogative writ, of a most extensive remedial nature; and may be issued in some cases, where the injured party has also a more tedious method of redress, as in the case of admission, or restitution to an office: but it issues in all cases where the party hath a right to have any thing done, and hath no other specific means of compelling its performance. A mandamus, therefore, lies to compel the admission or restoration of the party applying, to any office or franchise of a public nature, whether spiritual or temporal: to academical degrees; to the use of a meeting-house, &c. It lies for the production, inspection, or delivery of public books and papers; for the surrender of the regalia of a corporation; to oblige bodies corporate to affix their common seal; and to compel the holding of a court, &c. The writ of mandamus is made by statute (9 Ann. cap. 20.) a most full and effectual remedy for the refusal of admission, where a person is entitled to an office or place in any corporation, and also for wrongful removal, when a person is legally possessed. It may also be issued in pursuance of the statute, (11 Geo. I. cap. 4.) in case within the regular time no election shall be made of the mayor or other chief officer of any city, borough, or town corporate, or (being made) it shall afterwards become void; to require the electors to proceed to election, and proper courts to be held, for admitting and swearing in the magistrates so respectively chosen. This writ issues to the judges of any inferior court, commanding them to do justice according to the powers of their office, whenever the same is delayed. For it is the peculiar business of the court of king's bench to superintend all other inferior tribunals, and therein to enforce the due exercise of those judicial or ministerial powers, with which the crown or legislature has invested them; and this, not only by restraining their excesses, but by quickening their negligence, and obviating their denial of justice. A mandamus may, therefore, be had to the courts of the city of London, to enter up judgment (Raym. 214.); to the spiritual courts to grant an administration; to swear a church-

warden and the like. This writ is founded on a suggestion, by the oath of the party injured, of his own right, and the denial of justice below: whereupon, in order more fully to satisfy the court that there is a probable ground for such interposition, a rule is made (except in some general cases, where the probable ground is manifest), directing the party complained of to shew cause why a writ of mandamus should not issue; and if he shews no sufficient cause, the writ itself is issued, at first in the alternative, to do thus, or signify some reason to the contrary; to which a return or answer must be made, at a certain day. And if the inferior judge, or other person to whom the writ is directed, returns or signifies an insufficient reason, then there issues in the second place a peremptory mandamus, to do the thing absolutely; to which no other return will be admitted, but a certificate of perfect obedience and due execution of the writ. If the inferior judge or other person makes no return, or fails in his respect and obedience, he is punishable for his contempt by attachment. But if he, at the first, returns a sufficient cause, although it should be false in fact, the court of king's bench will not try the truth of the fact upon affidavits; but will for the present believe him, and proceed no farther on the mandamus. But then the party injured may have an action against him for his false return, and (if found false by the jury) shall recover damages equivalent to the injury sustained; together with a peremptory mandamus to the defendant to do his duty. Blackst. Combook iii.

MANDAMUS was also a charge to the sheriff, to take into the king's hands all the lands and tenements of the king's widow, who, against her oath formerly given, married without the king's consent.

MANDANS, the name of those Indians who inhabit the vicinity of the Missouri in Louisiana. These Indians are brave, humane, and hospitable; and are, upon the whole, the most friendly and well-disposed in this part of the country. About thirty years ago they lived in six villages, about forty miles below their present villages, on both sides of the Missouri. Repeated visitations of the small-pox, together with frequent attacks of the Sioux, have reduced them to their present number. They claim no particular tract of country. They live in fortified villages, hunt in their own neighbourhood, and cultivate corn, beans, squashes, and tobacco, which form articles of traffic with their neighbours, the Assiniboins: they also barter horses with them for arms, ammunition, axes, kettles, and other articles of European manufacture, which the Assiniboins obtain from the British establishments on the Assiniboin river. The articles which they thus obtain from the Assiniboins, and the British traders who visit them, they again exchange for horses and leather tents with the Crow Indians, Chyennes, Watapahatoes, Kiawes, Kanenavich, Staflan, and Kataka, who visit them occasionally for the purpose of traffic. Their trade may be much increased. Their country is similar to that of the Ricaras: and their population is increasing. Jefferson.

MANDAR, a town of the island of Celebes; 125 miles N. of Macassar.

MANDARA, a town of Egypt, on the E. branch of the Nile; 38 miles N. of Cairo.

MANDAREE, a town of Bengal; 30 miles N.N.W. of Midnapour.

MANDARIN, a name given by the Portuguese to the nobility and magistracy of the eastern countries, especially to those of China.

The word mandarin is unknown in this sense among the Chinese, who, in lieu thereof, call their *grandezes* and

magistrates *quan*, or *quan fu*, q. d. servant or minister of a prince.

In China they have two classes of mandarins, those of letters and those of arms, who compose what is called the nobility. These mandarins enjoy a very distinguishing privilege; in cases of necessity, they may remonstrate with the emperor, either individually, or as a body, upon any action or omission on his part which may be contrary to the interests of the empire. Their remonstrances are seldom ill-received by the sovereign; but he reserves to himself the right of paying to them that attention which he thinks they deserve. These mandarins are chosen from the *Literati* (which see), who are highly honoured in China. A mandarin of arms, however, is far from enjoying the same consideration as a mandarin of letters; and hence it happens, that there is little emulation among the higher military ranks.

In order to obtain the degree of *mandarin of letters*, it is necessary to pass through several other gradations: such as that of bachelor (*shie* or *tsai*), of licentiate (*kiu-jin*), and of doctor (*tsing-jsee*). Sometimes by favour it is sufficient to have attained to the two first degrees; but even those on whom the third is conferred obtain at first only the government of a city of the second or third class: and the manner of election is as follows: when several places happen to become vacant, the emperor invites to court a like number of literati, whose names are inscribed in a list. The names of the vacant governments are put into a box, which is raised so high, that the candidates can only reach it with their hands. They then draw in their turns, and each is appointed governor of that city of which he has drawn the name.

There are eight orders of mandarins in China. The first is that of "Calao." Their number depends upon the will of the prince. Ministers of state, the presidents of the supreme courts, and all the superior officers of the militia, are chosen from this order, the chief of which is called "Cheou-siang." He is president of the emperor's council, and in him the emperor always reposes great confidence. From the second order of mandarins are selected the viceroys and presidents of the supreme councils of the different provinces. Every mandarin of this rank is called "te-hiofe," i. e. a man of acknowledged ability. The title of "tchong-chueo," or school of mandarins, is given to those of the third order. One of their principal functions is that of secretary to the emperor. Certain employments are also assigned to each of the other classes. It is the business of mandarins of the fourth order, styled "y-tchuen-tao," when no particular government is entrusted to them, or when they belong to no fixed tribunal, to keep in repair the harbours, royal lodging-houses, and banks, of which the emperor is proprietor, in their district. The fifth order ("ping-pi-tao") have the inspection of the troops. The sixth ("tun-tien-pao") have the care of the highways. The seventh, or "ho-tao," have the superintendance of the rivers; and the eighth, called "hai-tao," that of the sea-coasts. In a word, the whole administration of the Chinese empire is entrusted to the mandarins of letters. From among them are chosen the governors of provinces, the governors of cities of the first, second, and third class, and the presidents and members of all the tribunals. Honours are lavished upon them, and every privilege and mark of distinction seem to be reserved for them alone. The homage which the people pay to every mandarin in office is almost equal to that which is paid to the emperor himself. Among the Chinese it is a received opinion, that their monarch is the father of the whole empire; that the governor of a province is the father of that province; and that the mandarin, who is governor of a city, is

also the father of that city. The homage which the mandarins of letters receive is not diminished by their great number. They amount to more than 14,000; and yet the veneration which the people entertain for them is always the same.

Public honours are more sparingly bestowed upon the *mandarins of arms*. They are never indulged with the smallest share in the government of the state; and yet, in order to be admitted to this rank, it is necessary, as well as for that of a mandarin of letters, to have passed through the three degrees of bachelor of arms, licentiate in arms, and doctor of arms. Strength of body, agility in performing the different military exercises, and a readiness in comprehending and executing orders, are all the previous qualifications required in mandarins of arms; and in these consist the various examinations which candidates are obliged to undergo before they can be admitted to that rank. Candidates for the two first degrees are always examined in the capital city of the province. The mandarins of arms have tribunals, the members of which are selected from among their chiefs. Among these they reckon princes, dukes, and counts, all which dignities, or other equivalent to them, are found in China. The principal of these tribunals is fixed at Peking, and it is composed of five different classes, viz. that of the mandarins of the rear-guard, named "Heou-fou," that of the mandarins of the left wing, called "Tfa-fou," that of the mandarins of the right wing, styled "Yeou-feou," that composed of the mandarins of the advanced main-guard, known by the name of "Tchong-fou," and that consisting of the mandarins of the advanced guard, called "Tlien-fou." These five tribunals are subordinate to a supreme tribunal of war, called "Long-tching-fou," which is also established at Peking. The president of this tribunal is one of the great lords of the empire, whose authority extends over all the officers and soldiers of the army. This president has for his assessor a mandarin of letters, who enjoys the title, and exercises the function of superintendent of arms. He is required to take the advice of two inspectors, who are named by the emperor; and when these four persons have agreed upon any measure, their resolution must still be submitted to the revision of a fourth supreme court, called "Ping-pou," which is entirely of a civil nature. The chief of the mandarins of arms is a general by birth; his power in the field is equivalent to that of our commander-in-chief. Under him there is a certain number of mandarins, who act as lieutenant-generals; other mandarins discharge the duty of colonels, captains, lieutenants, and ensigns. It is computed that there are in China between eighteen and twenty thousand mandarins of war; in this respect they are superior to the mandarins of letters; but the importance of the latter makes them to be considered the first and principal body in the empire. Thus, literature is encouraged, but military ardour is checked. The weakness of the mandarins of arms occasioned the conquest of China by the Tartars; and they have made no alteration since in these two branches of the Chinese constitution.

The viceroy of a province, distinguished by the title of "Tfong-tou," is always a mandarin of the first class, and his power in his district is almost unlimited. He never quits his palace without a guard of 100 men. He is the receiver-general of all the taxes collected in his province, and by him they are transmitted to the capital. All law-suits are brought to his tribunal, and he has the power of condemning criminals to death; subject, however, in the exercise of it, to the approbation or confirmation of the emperor. The viceroy, every three years, transmits to court an account of the conduct of subordinate mandarins; and such is his influence, that they

are accordingly continued in office or disgraced. The conduct of the viceroy himself is watched by inspectors, whose authority is formidable to him; and more especially to inferior mandarins, whom he has power to deprive of their employments for misbehaviour. In order to prevent partiality among the mandarins, relations in the fourth degree cannot have a seat at the same time in any of the provincial tribunals. Sick or superannuated mandarins are liberally provided for by government. All mandarins, whether Tartars or Chinese, of arms or of letters, are obliged, every three years, to give in-writing an exact account of the faults they have committed in discharging the duties of their office; and this kind of confession is examined at court, if the mandarin belong to any of the four first classes: but if it be made by any mandarins of the lower classes, it must be laid before the provincial tribunal of the governor. Informations, as the result of private inquiry, are addressed to the tribunal of mandarins, and there carefully examined: and distributive justice is exercised accordingly. Every mandarin who has discharged his duty with ability, zeal, and fidelity, is rewarded; but if he has been guilty of oppression and malpractices, he is not only dismissed, but impeached, and tried before the tribunal of crimes.

Since the time that the Tartars have rendered themselves masters of China, most of the tribunals, or courts of justice, &c. instead of one mandarin for a president, have two, the one a Tartar, and the other a Chinese.

The mandarinship is not hereditary. Duhalde. Grosier.

MANDARIN is also a name which the Chinese give to the learned language of the country.

Besides the proper and peculiar language of each nation and province, they have one common to all the learned men in the empire. This they call the mandarin tongue, or the language of the court. Their public officers, as notaries, lawyers, judges, and chief magistrates, write and speak the mandarin.

MANDATA, in *Geography*, a town on the S.W. coast of Sumatra; 45 miles S.E. of Indrapour.

MANDATARY, MANDATARIUS, he to whom a command or charge is given: and he that comes to a benefice by a mandamus is called by this name.

MANDATE, MANDATUM, in the *Canon Law*, denotes a rescript of the pope, by which he commands some ordinary, collator, or presenter, to put the person there nominated in possession of the first benefice vacant in his collation.

An apostolical mandate for the provision of benefices, is a monitory and comminatory letter from the pope to a bishop, by which he is enjoined to provide a subsistence for those who have been ordained by him, or his predecessors, from the tuncure to sacred orders inclusively; and to allow them their subsistence till they be provided with a benefice. This practice was occasioned by the bishops formerly laying hands on great numbers, and afterwards abandoning them to misery and want.

At first the popes only gave monitory mandates, which were no more than simple prayers and requests, that did not bind the ordinary; afterwards they gave preceptory mandates, which did not annul the provisions of the ordinary; at last they set up executory mandates, by which the provisions made by the ordinary, in prejudice of the mandate, were declared null; and the executor of the mandate, in default of the ordinary, conferred the benefice on the mandatory: but the pope's power in issuing these mandates is now very much restrained, and almost totally annulled.

MANDATES, *Royal*, to judges for interfering in private causes, constituted a branch of the royal prerogative, which

was given up by our English Justinian, Edward I.; and also by 2 Edw. III. c. 8, and 11 Ric. II. c. 10, it is enacted, that no commands or letters shall be sent under the great seal, or the little seal, the signet, or privy seal, in disturbance of the law; or to disturb or delay common right; and, though such commandments should come, the judges shall not cease to do right; which is also made a part of their oath by statute 18 Edw. III. ft. 4; and by 1 W. & M. ft. 2. c. 2, it is declared, that the pretended power of suspending, or dispensing with laws, or the execution of laws, by regal authority, without consent of parliament, is illegal.

MANDATTA, in *Geography*, a town of Hindoostan, in Candesh; 30 miles S.S.E. of Indore.

MANDAVEE, a town of Hindoostan, in Guzerat; 25 miles E. of Surat.—Also, a town of Hindoostan, in Baglana; 12 miles N.N.E. of Basseen.

MANDAWEE, a town on the S. coast of the island of Borneo. S. lat. 3° 20'. E. long. 113° 30'.

MANDAWEE *Islands*, a cluster of small islands in the East Indian sea, near the S. coast of Borneo. S. lat. 3° 20'. E. long. 113° 30'.

MANDAYA, a town on the W. coast of the island of Celebes. S. lat. 2° 33'. E. long. 119° 9'.

MANDE', *St.*, a small island in the English channel, near the coast of France. N. lat. 48° 51'. W. long. 2° 59'.

MANDEGELE, a town of the island of Ceylon, near the E. coast; 88 miles E.S.E. of Candy.

MANDELGUR, a town of Hindoostan, in the circar of Meywar; 14 miles N. of Cheetore.

MANDELLI, a town of Abyssinia; 150 miles E. of Gondar.

MANDELSLO, JOHN-ALBERT, in *Biography*, a native of Mecklenburg, was page to the duke of Holstein, and accompanied, as gentleman of the chamber, the ambassadors whom that duke sent to Muscovy and Persia in 1636. From the court of Persia, he went to Ormuz, and embarked for the Indies. On his return he drew up a "Journal of his Voyages," which is printed in the second volume of the *Travels of Olearius*, who was secretary to the embassy, and is held in much esteem. Moreri.

MANDELSTEIN, in *Mineralogy*. See TRAP.

MANDERA, in *Geography*, a town of Africa; 120 miles N.E. of Sennaar. N. lat. 14° 45'. E. long. 35° 10'.

MANDERSCHIED, a town of France, in the department of the Sarre, and chief place of a canton, in the district of Prum; 21 miles N.N.E. of Treves. The place contains 323, and the canton 2595 inhabitants, in 24 communes.

MANDERY, a town of Hindoostan, in Dowlatabad; 10 miles W.N.W. of Ranapour.

MANDEVILLE, Sir JOHN, in *Biography*, a celebrated early traveller, was born at St. Albans about the beginning of the fourteenth century. He was intended for the profession of physic, which he probably practised, but an ardent desire of visiting foreign countries induced him, in 1332, to set out upon a course of travels, in which he spent more than thirty years. During this period he extended his peregrinations through the greatest part of Asia, Egypt, and Lybia, making himself master of many languages, and collected a great mass of information, which he committed to writing in Latin, English, and French. He died at Liege in the year 1372. The only genuine edition of his travels is thus entitled, "The Voiage and Travaile of sir John Mandeville, knight;" it was printed from the original MS. in the Cottonian library, 1727. The character of sir John, for veracity, has been very differently regarded by different and competent judges; his narratives were highly esteemed in his own age, and they rendered him celebrated throughout Europe.

Europe. By some of his remarks it should seem that he had a general acquaintance with the science of the period in which he flourished.

MANDEWAR, in *Geography*, a town of Hindoostan, in Bahar; 32 miles S.S.W. of Arrah.

MANDIBLE, the *Jaw*, in *Anatomy*. See *MAXILLA* and *CRANIUM*.

MANDIBULARES, or *MANDUCATORII Musculi*. See *MASSETER* and *DEGLUTITION*.

MANDIL, or *MANDRIL*, the name of a kind of cap or turban worn by the Persians.

The mandil is formed by first wrapping round the head a piece of fine white linen five or six ells long; over this they wrap, in the same manner, a piece of silk of the same length, and often times of great value. To make the mandil genteel, care must be taken, that, in wrapping the silk, it be so managed, as that the several colours found in the several folds make a kind of waves, somewhat like what we see on marbled paper.

The dress is extremely majestic, but at the same time very heavy: it serves either as a shelter to the head from cold, or as a screen from the excessive heat of the sun; it is said, that a blow of a cutlass will not penetrate it. In rainy weather they cover it with a kind of case or hood, made of red cloth.

The mode of the mandril has been for some time altered: during the time of Schah-Abbas II. it was round at top; in the time of Schah-Soliman, they brought one end of the silk out of the middle of the mandril over the head; and, lastly, in the reign of Schah-Husseïn, the end of the silk, in lieu of its being gathered as before, was plaited in manner of a rose; and this the Persians account extremely graceful, and use it to this day.

MANDING, or *MANDINGA*, in *Geography*, a country of Africa, situated on both sides of the river Joliba or Niger, towards its sources, and supplying those streams or rivers, called Bafing and Kokoro, that form the Senegal. This country comprehends a considerable tract from between 11° and 13° N. lat. and between about 5° and 7° W. long. The inhabitants of this country, and those of other districts in the western part of Africa, who have probably migrated from hence, are called Mandingoes, and their language has a considerable extent. The government of this country is said to be republican, though that of the other African states is, in general, monarchical. In their complexions and persons, the Mandingoes are easily distinguished from those Africans who are born nearer to the equator; and yet they consist of very distinct tribes, some of which are remarkably tall and black; and there is one tribe among them (called also the Phulies) that seemed to Mr. Edwards to constitute the link between the Moors and Negroes, properly so called. They are of a less glossy black than the Gold Coast negroes; and their hair, though bushy and crisped, is not woolly, but soft and silky to the touch. Neither have the Mandingoes, in common, the thick lips and flat noses of the more southern natives; and they are, in a great degree, exempt from that strong and fetid odour which exhales from the skin of most of the latter; but in general they are not well adapted for hard labour. After all, they differ less in their persons, than in the qualities of the mind, from the natives of the Gold Coast; who may be said to constitute the genuine and original unmixed negro, both in person and character. See *KOROMANTYN Negroes*.

The Mandingoes, in general, are of a mild, sociable, and obliging disposition; the men are commonly above the middle size; and the women are sprightly, good-humoured, and agreeable. The dress of both sexes consists of cotton cloth, of their own manufacture; that of the men is a loose frock,

not unlike a surplice, with drawers which reach half-way down the leg, and they wear sandals on their feet, and white cotton caps on their heads. The women's dress consists of two pieces of cloth, each of which is about six feet long and three broad; one of which they wrap round the waist, which, hanging down to the ancles, serves for a petticoat, and the other is thrown negligently over the bosom and shoulders. In the construction of their houses, the Mandingoes, like the other Africans, in this part of the continent, content themselves with small hovels. A circular mud-wall, about four feet high, upon which is placed a conical roof composed of the bamboo cane, and thatched with grass, forms their common dwelling for people of all ranks. Their household furniture is no less simple; a hurdle of canes placed upon upright stakes, about two feet from the ground, upon which is spread a mat, or bullock's hide, answers the purpose of a bed; a water jar, some earthen pots for dressing their food, a few wooden bowls and calabashes, and one or two low stools, are their other domestic articles. As every man of free condition has a plurality of wives, it becomes necessary, for the prevention of disputes, to accommodate each lady with a hut to herself; and all the huts belonging to the same family are surrounded by a fence constructed of bamboo canes, split and formed into a sort of wicker work. The whole inclosure is denominated a "firik," or "furk." A number of these inclosures, separated by narrow passages, constitute what is called a town; in which the houses are placed without any order, except that the door is situated towards the south-west, in order to admit the sea-breeze. Their religion is, as we may conceive, blended with many superstitious opinions and practices. Although they admit the existence of a deity, as the maker and preserver of all things, they consider him as too remote and too exalted in his nature to regard the supplications of wretched mortals, or to alter for their sake any of his purposes and decrees. The prayers which are offered up at the appearance of the new moon are performed merely in conformity to a custom which has been transmitted to them from their ancestors. Subordinate spirits, as they imagine, are entrusted by the almighty with the superintendance and direction of all human concerns; and these spirits are much under the influence of certain magical ceremonies. The rite of circumcision prevails in this part of Africa even by those negroes, who have never received the religion of Mahomet. The Jaloffs confine it to the males; but the Mandingoes, both Soninkees and Bushreens, extend the ceremony to both sexes, as the ancient Egyptians did before them; and the operation is performed at the commencement of puberty. Mr. Park, in his "Travels," informs us, that the negroes, in general, did not seem to consider this painful rite as an act of religious duty, and as such, essential to their future salvation; but rather as an operation of physical necessity; without which the marriage state could not, in their opinion, be prolific. (See *CIRCUMCISION*.) We learn also from this observing and intelligent traveller, that the negroes of this part of Africa firmly believe in a life beyond the grave, and a state of retribution after death, in which good men will be rewarded, and bad men punished. He conversed with the natives of all descriptions on this important subject, and pronounces, without the smallest hesitation, that a conviction of this great truth among the negroes is entire, hereditary, and universal.

Among the Mandingoes there are few or no instances of longevity: at 40, most of them become grey-haired and wrinkled; and few survive the age of 50 or 60, counting their years by the number of rainy seasons, one of which only occurs in the year. Their diseases, however, are few;

the principal being the dysentery, the yaws, the elephantiasis, and a leprosy of the worst kind. The Guinea worm is also in some places very common, especially at the commencement of the rainy season, and this they attribute to bad water; to which they likewise ascribe the goitres, or swellings of the neck, which are very common in some parts of Bambarra.

The principal of their musical instruments are the koonting, a sort of guitar with three strings; the korro, a large harp with eighteen strings; the simbing, a small harp with seven strings; the balafon, composed of twenty pieces of hard wood of different lengths, with the shells of gourds hung under them, for increasing the sound; the tangtang, a drum open at the lower end; and the tabala, a large drum used for causing an alarm through the country. Besides these, they make use of small flutes, bow-strings, elephants' teeth, and bells; and at all their dances and concerts, clapping of hands constitutes a necessary part of the chorus.

The beverage of the pagan Negroes is beer and mead, in the use of which they are apt to indulge to excess. The Mahometan converts drink nothing but water. The natives of all descriptions take snuff, and smoke tobacco; and their pipes are made of wood, with an earthen bowl of curious workmanship. But in the interior districts, the greatest of all luxuries is salt. The arts of weaving, dyeing, sewing, &c. are universally practised; but the only artists, acknowledged as such by the Negroes, are the manufacturers of leather and iron. They tan and dress leather very expeditiously, by first steeping the hide in a mixture of wood-ashes and water, until it parts with the hair; and afterwards using the pounded leaves of a tree called goo, as an astringent. Most of the African blacksmiths are acquainted with the method of smelting gold; in which process they use an alkaline salt, obtained from a ley of burnt corn-stalks, evaporated to dryness. They likewise draw gold into wire, and form it into a variety of ornaments, with great ingenuity and taste. Gold is found in every part of Mandingo, in small grains, nearly in a pure state, from the size of a pin's head to that of a pea.

The Mandingoes, most of whom are profelyted to Mahometanism, have frequent wars with each other, as well as with those nations regarded by them as enemies of their faith. The advantage possessed by a few of these people, of being able to read and write, is a circumstance on which the Mandingo Negroes in the West Indies pride themselves greatly among the rest of the slaves, over whom they consider themselves as possessing a decided superiority; and in truth, says Mr. B. Edwards, they display such gentleness of disposition and demeanour, as would seem to be the result of early education and discipline, were it not that, generally speaking, they are more prone to theft than any of the African tribes. It has been supposed that this propensity, among other vices, is natural to a state of slavery, which degrades and corrupts the human mind in a deplorable manner; but why the Mandingoes should have become more vicious in this respect than the rest of the natives of Africa, in the same condition of life, is a question not easily resolved. Edwards's Hist. of the West Indies, vol. iii.

MANDIOLY, an island in the East Indian sea, of a semicircular form, about 120 miles in circumference, separated from the west coast of Gilolo by the straits of Patientia, and belonging to the sultan of Bachian. The island is centrally traversed by the equator. E. long. 124°.

MANDOE, a small island in the German ocean, near the coast of Sleswick; 10 miles W.S.W. of Ripen. N. lat. 55° 10'. E. long. 8° 32'.

MANDOLA, a town of Italy, in the marquisate of Ancona; 30 miles N.E. of Spoleto.

MANDOLA, and *Mandora*, Ital.; *Tessudo minor*, Lat.; *Mandole*, and *Mandoline*, Fr.; a very small instrument, in form of a violin, with four strings, and a fretted neck, played with a quill in the right hand instead of a bow. About thirty years ago there was a Neapolitan here, of the name of Francesco, who played admirably on this diminutive tinkling instrument, which had very little tone or variety of expression; yet, by his taste, fancy, and enthusiasm, Francesco entertained lovers and nice judges of music during several hours, without tiring them with its monotony, or rather total want of tone.

MANDORE, a small lute or guitar, with four strings, tuned fourths and fifths, sometimes thrummed with the finger, and sometimes played with a quill, like the mandoline.

MANDRA, in *Geography*, a town of Russia, in the government of Irkutsk; 76 miles N.E. of Kirensk.

MANDRAGORA; in *Botany*. See ATROPA and DUDAIM.

MANDRAGORA, *Chinese*, is the plant *Ginseng*; which see.

MANDRAKE. See ATROPA and DUDAIM.

The roots of mandrake vary both in form and colour, being either divided or entire, and externally brown or black: hence they have been distinguished into male and female. The internal substance is white, and to the taste somewhat viscid, bitter, and nauseous.

MANDRAKE, in the *Materia Medica*, has been recommended in case of barrenness, but without foundation. All the eminent writers on mandrake represent the root to be an adonyne and soporific; but in large doses it is said to excite maniacal fury. They employed it principally in continued watchings, and in those more painful and obstinate affections which were found to resist less powerful medicines. It was also used in melancholia, convulsions, rheumatic pains, scrophulous tumours, &c.: and for these purposes, either the expressed juice of the cortical part of the root, inspissated, or a vinous decoction or infusion of the root, was directed. Pallas also mentions it as of frequent use for chronic diseases in some parts of Russia. (See ATROPA *Mandragora*.) The experiments, recited under that article, shew that the mandrake acts as an opiate; which confirms the opinion entertained by the ancients: and hence it may be concluded, that if it be not administered with great care, it may prove a deleterious and mental narcotic. This caution is the more necessary, as the berries of mandrake are said to have been eaten without producing any bad effect. Woodville.

MANDRAKE-WINE, *Mandragorites Vinum*, a sort of medicinal impregnation of wine with the virtues of mandrake root. It is prepared by cutting into thin slices half a pound of the bark of mandrake roots, and stringing them on a thread, and letting them down into a vessel containing nine gallons of white wine, so that they may hang loosely in it, and by that means fully impregnate it with their virtues. It was used in small doses as an anodyne and soporific. It had the same effects also, if only smelled to, and was sometimes injected in clysters to the same purpose. They say that half a pint of this liquor, mixed with twelve times its quantity of wine, brings on a carus; and that even a smaller dose than this, less diluted, is mortal. See the preceding article, and ATROPA *Mandragora*.

MANDREL, a kind of wooden pulley, making a member of the turner's lathe.

Of these there are several kinds; as,

MANDRELS, *Flat*, which have three or more little pegs or points near the verge, and are useful for turning flat boards on.

MANDRELS, *Pin*, which have a long wooden shank to fit into a round hole made in the work to be turned.

MANDRELS, *Hollow*, which are hollow of themselves, and used for turning hollow work.

MANDRELS, *Screw*, for turning screws, &c.

MANDRIL, in *Zoology*, a species of baboon, or monkey. See *SIMIA Maimon*.

MANDSHURES, in *Geography*, people of Siberia who form two nations, the one called Mandshu or Mandshures, and the other Tunguses. Both these nations are related by descent, as we may conclude from their traditions, their language, and their bodily structure. The whole swarm together possess extensive countries and deserts in eastern Siberia, and in the northern Mongolia. The Mandshu are still very powerful; one of their princely families being in hereditary possession of the throne of China. Before the Russians entered Siberia, the Mandshures were in possession of all Daouria, or the eastern Siberia, from the Baikal quite to the Mongolian mountains, together with the regions adjacent to the Amoor, and its collateral rivers. They were at that time divided into several stems, of which the Daourians inhabited the parts about the Selenga and the Upper Amoor; the Dutschares dwelt between the Argoon and the Schilka; the Atschares about the middle Amoor; and the Ghiliaks at the mouth of the Amoor, on the coasts of the Eastern ocean.

The Daourian Mandshu, not waiting for the arrival of the Russians in their territories, retreated to the Amoor, and into the empire of China. At the first Russian expedition, about the middle of the seventeenth century, the Daourians and Dutschares were subjects of the Chinese emperor, who, as a native Mandshu, aided their flight, and afforded them protection. The Ghiliaks and Atschares subsisted then in a state of independence, and accepted the Russian patronage without opposition. Their example was followed by considerable multitudes of the other two stems; but most of them, by orders of the Chinese government, were transported from the Amoor, of which the Russians had made themselves masters, farther towards China. Afterwards, at a peace concluded at Nertschinsk, the whole of the Amoor, with all the Mandshures belonging to Russia, was ceded to China; and at present, the mountain-ridge Stannovoi Khrebet, which stretches from Daouria north-eastward between the rivers Lena and Amoor to the Eastern ocean, forms the boundary betwixt the two empires. In the frontier mountains themselves, however, are no Mandshures, but Tunguses, who are partly tributary to the Chinese, partly to Russia, or live in complete independence.

The Mandshu, particularly the Daourian, while they inhabited the modern Russia, were by no means an uncivilized people. According to their written accounts and traditions, they had a constitution composed of nomadic and civil parts, and adapted to their situation, their mode of life, &c. They lived peaceably among themselves and with their neighbours, attending sedulously to agriculture, grazing, and even to mining. Traces are still seen about the Bargusin, and other rivers, of their gardens, orchards, and fields, artfully laid out, and watered with artificial water-courses. The Daourian mine-works on the banks of the Argoon, still famous under the name of the Nertschinkian mines, as well as all Daouria, afford numerous proofs of the

mineral labours of the ancient Daourians. Tooke's *Russ. Emp.* vol. i. See TUNGUSES.

The country of the Mandshures is divided by the Chinese into three great governments. 1. That of Chin-yang or *Chen-yang*; which see. 2. The government of Kiren-Oula. (See KIRIN.) 3. The government of *Tschibcar*; which see. See *Mantchew* TARTARS.

MANDSJADE, in *Botany*, is an Indian siliquous or pod-bearing tree, with a spiked pentapetalous flower, and long pods containing nodous scarlet-coloured beans; the tree is one of the tallest in the kingdom of Malabar, bears fruit the twentieth year after planting, and living near two hundred years.

The wood is of common use for various purposes, on account of its solidity; the leaves, reduced to powder, are used in the pagan religious rites; the seeds, which are not ungrateful to the taste, are eaten by the common people, either boiled whole or ground to a meal; and are, besides, of great use to goldsmiths and jewellers, who, on account of their exact equality, employ them instead of grains in weighing their wares; for each maljelina, as they call them, weighs four grains, such as are in use among the goldsmiths; who, also of the bruised seeds, moistened with water and borax, prepare a glue for conglutinating the finer sort of vessels, when broken. Of the bruised leaves the physicians prepare a potion for mitigating pains in the loins.

MANDU, in *Geography*, a town of Hindoostan, in Myfore; 10 miles N.E. of Seringapatam.

MANDUCATION, the action of *chewing*, otherwise called *mastication*.

Manducation is a term seldom used but in speaking of the eucharist. The Catholics maintain a real manducation of the body of Christ; the reformed, on the contrary, take this manducation to be only figurative, and by faith. St. Augustin calls it *spiritual manducation*.

MANDUN, in *Geography*, a town of Hindoostan, in Guzerat; 30 miles S.E. of Janegur.

MANDURIA, an ancient town of Naples, in Calabria Citra. After having sunk into decay, it was rebuilt at a little distance from its former site, and called "Casale Nuovo," which name it retained till the year 1790, when, at the request of the inhabitants, the original name was restored. It contained about 4000 inhabitants. In 1783 it suffered very much by an earthquake.

MANE', a sea-port on the W. coast of Madagascar, at the mouth of the river Manfiatre. S. lat. 33 35'.

MANE of a Horse, in the *Manege*. (See HORSE.) The adjustment of the manes of horses was an object of particular attention among the Armenians, and others who valued themselves on their breed of these animals. Some, as we learn from Vegetius, used to cut them clear off, a practice which he condemns, because it rendered the horse unsightly and deformed. Others clipped them, so as to make them resemble an arch or bow, called by us an "hog's mane." Others again separated the mane into notches, like the battlements of a tower; while some cut it close, but only on one side, leaving the hair long and flowing on the other, which was very graceful and becoming: the side on which the mane was turned and reposed being always to the right. To this Virgil alludes, when he directs the mane to be laid on the right shoulder.

"Denfa juba, et dextro jactata recumbit in armo."

This method was practised by the Persians as well as the Armenians; and appears, by the above citation, to have been

been in use with the Romans, as well as that of shearing the manes of their "manni" or nags; whence Propertius says, his mistress Cynthia was carried in her litter by shorn horses.

"Et mea detonsis advecta est Cynthia mannis."

Varro likewise directs the mane to be turned to the right side. They also tied it in knots, or plaited it, as the word "implicata" (lib. iv. c. 7.) aptly expresses. No particular reason is assigned for always turning the mane on the right side: it might be owing, perhaps, to the custom of mounting on the right, which was frequently, but not always, the practice; and in that case, the mane hanging on the side, from which the horseman got up, offered itself to his hand to assist him in the action; while we, without any meaning, always mount on the left, and always turn the mane to the right. The Armenians, as well as the Parthians, had another method of trimming their horses, by which they made them as it were "double maned;" for the hair being cut away in the middle, the mane was divided, and falling down, clothed each side of the neck; a fashion sometimes used at present, but generally among coach horses. Berenger's Hist. &c. of Horsemanship, vol. i.

MANE-SHEET, is a sort of covering for the upper part of a horse's head, and all round his neck, which at one end has two holes for the ears to pass through, and then joins to the halter upon the fore-part of the head, and likewise to the surcingle, or long girth, upon the horse's back.

MAN-EATER'S ISLAND, in *Geography*, a small island in the Indian sea, near the N. coast of the island of Java, between Batavia and Bantam.

MANEBELLO, a small island in the East Indian sea. S. lat. 4° 9'. E. long. 131° 58'.

MANEGE. A horse is said to manege when he works upon volts and airs, which supposes him broke and bred. See **MANAGE**.

MANEGE for a Soldier's Horse, is a gallop of unequal swiftness, but so that the horse changes hands readily.

MANEGE, High, is the high or raised airs, which are proper for leaping horses. See **AIRS**.

MANEGED. A horse is said to be thoroughly maneged, or a finished horse, that is well broken, bred, and confirmed in a particular air or manege, so as to bear well upon the hand, know the heels, and sit well upon the hips.

MANELLI, FRANCESCO, of Tivoli, in *Biography*, composer of the first Italian opera that was performed on a public stage in Venice, in 1635. The drama, intitled "Temistocle," was written by Ferrari, himself a composer; but the preference given to Manelli, either by the author of the words, or by the public, at such an era, is an indisputable proof of respect for his abilities; and a still less suspicious compliment to his talents, was his being retained by the same poet, and the same public, to compose a second opera, "Andromeda," in 1637. In subsequent years he composed four more operas, which had great success. See **OPERA** and **VENICE**.

MANEQUIN, among *Painters*. See **LAYMAN**.

MANERBIO, in *Geography*, a town of Italy, in the department of the Mela; 12 miles S. of Brescia.

MANES, or **MANI**, in *Biography*. See **MANICHÆES**.

MANES, a poetical term, signifying the shades or souls of the deceased.

The heathens used a variety of ceremonies and sacrifices to appease the manes of those who were deprived of burial. See **LEMURES** and **LEMURIA**.

MANES, Dii, were the same with *inferi*, or the infernal

gods, who tormented men; and to these the heathens offered sacrifices, to assuage their indignation.

The heathen theology is a little obscure with regard to these gods, manes. Some hold, that they were the souls of the dead; others that they were the genii of men; which last opinion suits best with the etymology of the word, and such is their origin according to Hesiod.

The heathens, it is pretty evident, used the word manes in several senses; so that it sometimes signified the ghosts of the departed, and sometimes the infernal or subterraneous deities, and in general all divinities that presided over tombs, and the ghosts that were thought to wander about these tombs. Accordingly, their true original may be referred to a prevailing opinion, that the world was full of genii, some of whom attended on the living, and others on the dead: that some were good and others bad, and that the former were called "familiar lares," and the latter lemures or larvæ. Thus, when Virgil says, "Quisque suos patimur manes," it is, according to Servius, as if he had said, "we have each of us our genius." Apuleius, in his explication of the *Lemures* and *Larvæ* (see both these articles), says that the lares and larvæ are denominated "Dii Manes," and that the designation of gods is added to them by way of honour. Agreeably to this opinion it is no wonder that the ancients should confound the manes with the lares and the lemures.

The evocation of the manes of the dead seems to have been very frequent among the Thebans; but it was expressly prohibited by the Romans. See **LARES**.

MANESSON-MALLET, ALAN, in *Biography*, a native of Paris, who flourished in the 17th century, and who was distinguished in the service of the king of Portugal as a military engineer. He is known, however, chiefly by his works, which continue still to be in request: they are "Martial Studies, or the Art of War," 1691, in three vols: "A Description of the Universe," &c. 1683, in five vols: "Practical Geometry," 1702, in four vols. 8vo. His works are all illustrated with plans, maps, and other engravings.

MANETHOS, an ancient Egyptian historian, called the Sebennitic, from the place of his origin, was high-priest of Heliopolis in the reign of Ptolemy Philadelphus, about the year 304 B.C. He wrote in the Greek language a history of Egypt, the subject matter of which he asserts to have been extracted from certain pillars in the Siriadic land, on which inscriptions had been made in the sacred dialect of Thoth, the first Mercury, which after the flood were translated into the Greek tongue, but were written in the sacred character, and were laid up in books in the sacred recesses of Egypt by the second Mercury. But this account, which certainly related to the earlier portions of the history, is so incredible, by its reference to the Greek language, at a period when it could not be known in Egypt, that the writers of the Universal History suspect some mistake or corruption in the passage of Eusebius containing it. The work of Manethos was divided into three tomes, the first of which comprehended the history of the gods and demi-gods, who in his estimation were mortal men very eminent for virtue; the second that of the eight dynasties of kings, and the third of twelve. The history, which is, in a good measure, fabulous, is lost, but his dynasties have been preserved in the chronicle of Eusebius. Some fragments of the history are to be found in Josephus's work against Apion.

MANETTI, GIANOZZO, was born at Florence in 1396: he was intended for trade, and received an education suitable to it, but being put into the house of a banker when he was only ten years of age, he became disgusted with the

employment, and was accordingly permitted to apply his mind to the various kinds of literature that were then cultivated. During nine years he devoted himself to these pursuits, after which he was appointed by the Florentines to give public lectures on the ethics of Aristotle, which were attended by a vast number of pupils. From the age of thirty-five, he was employed by the state in various honourable offices, and was several times deputed to preside over the public studies, which always flourished under his superintendance. He was sent on embassies to the republic of Genoa; to king Alphonso; to Francis Sforza; to the popes Eugenius IV. and Nicholas V.; to several of the Italian states, and to the emperor Frederic III., and on all these occasions he gave proof of great prudence and dexterity in the management of affairs, and of an eloquence which was the object of universal admiration. Notwithstanding the high rank to which he had attained, he found cause for dissatisfaction at his own court, and retired to that of Nicholas V., who received him with great honour; but as he was cited to appear at Florence, on pain of banishment, the pope deputed him to go thither in the character of his ambassador. His conduct in this new situation so ingratiated him with his countrymen, that from a culprit he became a principal magistrate. He afterwards returned to Rome, and was made secretary to Nicholas V., in which post he was continued by Calixtus III. Going to Naples on private business, Alphonso kept him there with a pension for three years, during which he composed the greater part of his works. He died in 1459 with the character of one of the most learned and excellent men of his age. He was deeply skilled in the Hebrew language, and employed his great learning in this respect to confute the Jews from their own scriptures. He wrote a work against their tenets in ten books, which is said still to remain in MS. in the Laurentian library. Among his printed works are, "The History of Pistoia;" "The Lives of Nicholas V., Dante, Petrarch, and Boccaccio;" "The Funeral Oration of Leonardo Bruni;" "De Dignitate et Excellentia Hominis," and some "Orations."

MANETTIA, in *Botany*, was named by Mutis and Linnæus, in honour of Xavier Manetti, curator of the Botanic Garden at Florence, who was born in the year 1723, and died in 1784. He published, in 1747, a catalogue of such plants as grew in the garden at Florence, interspersed with observations on the salutary and hurtful properties of vegetables. He also wrote a treatise upon the domestic economy of making bread from different kinds of corn, but upon the whole prefers that which is made from *Triticum polonicum*. Linn. Mant. 553. Schreb. 75. Willd. Sp. Pl. v. 1. 624. Mart. Mill. Dict. v. 3. (Nacibea; Aubl. Guian. 95. t. 37. Juss. 199. Lamarck Illustr. t. 64.)—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Convolv.*, Linn. *Rubiaceæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, of eight linear, concave, hairy, permanent leaves. *Cor.* of one petal, salver-shaped; tube cylindrical, longer than the calyx, marked on the inside with four lines; limb divided into four segments, which are shorter than the tube, ovate, obtuse, bearded within. Nectary a rim surrounding the receptacle, quite entire, concave. *Stam.* Filaments four, thread-shaped, very small, placed at the mouth; anthers linear, incumbent, two-celled. *Pist.* Germen inferior, turbinate, compressed; style thread-shaped, bent down, the length of the tube; stigma cloven, thickish, obtuse. *Peric.* Capsule turbinate, compressed, furrowed on both sides, of one cell and two valves, or separable as it were into two capsules. *Seeds* few, flat, winged,

orbiculate with a central embryo, imbricated on a pulpy oblong receptacle.

Eff. Ch. Calyx of eight leaves, superior. Corolla four-cleft. Capsule inferior, of two valves and one cell. Seeds imbricated, orbicular, with a central embryo.

1. *M. reclinata*. Linn. Mant. 558. Swartz. Prod. 37.—Leaves ovate, acute, downy. Stem reclined, herbaceous.—A native of Mexico.—*Root* annual. *Stem* weak and branching. *Leaves* opposite, on footstalks, crowded, somewhat fringed, an inch and half long. *Footstalks* very short, hairy. *Stipulas* opposite, closely fastened to the stalks, semicircular, very short. *Flower-stalks* axillary, solitary, shorter than the leaves, many-flowered; partial stalks opposite, round, hairy, furnished with a single, small, acute bractea. *Flowers* white.

2. *M. Lygislum*. Swartz. Prod. 37. Willd. n. 2. (Petefia Lygislum; Linn. Sp. Pl. 160. Lygislum; Brown. Jam. 142. t. 3. f. 2.)—Leaves ovate, acute, veiny. Stem twining, somewhat shrubby.—Native of Jamaica.—This weakly shrub has a branched, twined stem, about seven feet in length. *Leaves* opposite, on footstalks, large. *Flowers* in bunches, terminal, on long, branched footstalks, generally two together, or solitary. Swartz observes that the calyx of this plant has eight leaves, and that the seeds are imbricated, which induced him to refer it to the present genus.

3. *M. coccinea*. Willd. n. 3. (Nacibea coccinea; Aubl. Guian. t. 37. f. 1.)—Leaves ovate, acuminate. Clusters many-flowered. Stem twining, shrubby.—A native of Guiana, where it flowered and fruited in May.—*Root* perennial. *Stems* numerous, knotty, branched, square. *Leaves* at the knobs, in pairs, opposite, on footstalks, smooth. *Flowers* in clusters, the tube of the corolla white, marked with red dots; the limb of a scarlet colour above, downy; the mouth of the tube closed with yellow hairs.

4. *M. picta*. Willd. n. 4. (Nacibea alba; Aubl. Guian. t. 37. f. 2.)—Leaves ovate, acute. Calyx four-toothed. Stem twisting and climbing, shrubby.—Found at the same place with the last, from which it differs in having the calyx four-toothed; the corolla shorter and white; the leaves broader, and variegated with yellow.

5. *M. lanceolata*. Willd. n. 5. Vahl. Symb. p. 1. 12: (Ophiorrhiza lanceolata; Forfk. Descr. 42.)—Leaves lanceolate. Calyx five-cleft, unequal. Flowers pentandrous. Stem erect.—A native of the lofty mountains of Hadie, in Arabia. *Stem* shrubby. *Flower-stalks* three together, terminal, the lateral ones thrice as long as that in the centre, cloven at the top. *Flowers* at first heaped together, then racemose, all directed one way.—Vahl observes that this species is nearly allied to *Cinchona*, and that it differs from the rest of this genus in the number of stamens and segments of the calyx.

MANFELOUT, or MAMFLOT, in *Geography*, a town of Egypt, on the left side of the Nile, a mile from that river. Its name signifies in Arabic "the place of Lot's exile;" and it is so called, according to the Jesuit F. Vanflebel, who founds his opinion on a tradition of the Copts; because a person of the name of Lot was banished thither by his brother, one of the ancient kings of Egypt. The town is tolerably large, being about a mile in circumference, and much handsomer than Miniet; its streets are wider and better paved. It is the capital of a district, and agreeably situated in a country that furnishes abundance of productions of every kind; and its walls are shaded by fruit-trees, overtopped by a number of lofty palms. It is governed by a kiaschef or cashaf, and is the see of a bishop, who presides over about 200 Christians. Its commerce consists of all

forts

sorts of grain, and of linen cloths, which are manufactured here in great quantities. The Turks have different mosques, as well as a garrison, in this place. Opposite to it is a Coptic convent, on the E. bank of the Nile, which is wholly inclosed with high walls, and into which the only mode of admission, in order to be secure against the rapacious Arabs, is that of being hoisted up in a basket, by means of a pulley; whence it has obtained the name of the "Convent of the Pulley." Two leagues below Manselout, on the east bank of the Nile, is a chain of very high mountains, formed entirely of barren rock; the waters of the river have undermined them, so that their summit projects considerably beyond their base. This chain of rocks is called the mountain of "Aboufeda," from the name of a Mussulman saint who is buried there, and in honour of whom a small chapel has been erected. By the side of this monument of piety, or rather of the absurd superstition of the Mahometans, some men of the same religion, who are devout worshippers of saint Aboufeda, and, at the same time, determined robbers, live in retreats dug in the rock, and formerly, as it is said, inhabited by Anchorites. But these excavations, as well as those in Scheick Abadé, and in the two chains of mountains between which the Nile runs, in the upper part of Egypt, are probably burial places and ancient tombs. However this be, the persons who now occupy them are the most formidable pirates that obstruct the navigation of Egypt, and also the most difficult to be exterminated, as they take refuge in the inaccessible cavities of these mountains. Manselout is 13 miles N.N.W. of Siout. N. lat. $27^{\circ} 42'$. E. long. $31^{\circ} 36'$. Sonnini's Travels in Egypt.

MANFORT, a town of Africa, on the Gold Coast, in the country of Fantin.

MANFRED, or MAINFROY, in *Biography*, king of Naples and Sicily, was natural son of the emperor Frederic II.; on the death of his father in 1250, he became possessed of the principality of Tarento, and some adjacent counties. When his brother Conrad arrived from Germany, to take possession of the Sicilian kingdoms, he became jealous of Manfred's power and abilities, and took from him a part of his inheritance, but upon the death of Conrad, he became possessed of the regency in behalf of his nephew, the infant Conradin. The pope, however, claimed the kingdom as fief to the holy see, and excommunicated Manfred, who being unable to make opposition, received his holiness very submissively in Naples. Soon after he raised a body of troops, and defeated the papal army, and after other successes he recovered all the Neapolitan territory, and was received with great rejoicings into the city of Naples, where he behaved with much generosity and clemency. He afterwards passed over to Sicily, and a report being spread of the death of Conradin, he was unanimously elected king by the Sicilian and Apulian barons, was accordingly crowned at Palermo in 1258, and by a mild and very equitable administration, secured the affections of the people. His peace was in a short time disturbed by intelligence, that Conradin was not only alive, but claimed the crown as his birth right; to which Manfred replied, that he had conquered the kingdom from two popes, and what he had won by his valour he could not think of resigning, but would leave the kingdom to Conradin at his death. He founded a new city on the Adriatic, to which he gave the name of Manfredonia, and peopled it with the inhabitants of Siponto, which he destroyed on account of its unhealthy situation. His troops gained a signal victory over the Guelfs, in consequence of which the city of Florence acknowledged his sovereignty. In 1262, pope Urban IV.

published a crusade against him, and in the following year conferred the kingdoms of Naples and Sicily upon Charles of Anjou, brother of the French king Lewis IX. Charles prepared to invade the country, and Manfred was as zealous in his dispositions to resist him; but he was at length betrayed by his barons, who secretly negotiated with his rival; and in February 1266, Manfred, engaging with the French army near Benevento, after fighting with great valour, was defeated and slain. As an excommunicated person, his body was thrown into a ditch, and buried under a heap of stones. The pope afterwards ordered it to be taken up, and carried out of the territories of the church. Manfred, though blackened by his enemies, displayed the talents and virtues of a great sovereign; he was accomplished beyond most princes of his time, and if he were guilty of criminal ambition in gaining a crown, he wore it with honour. Mod. Univ. Hist.

MANFREDI, EUSTACHIO, an Italian mathematician and astronomer, son of a notary, was born in the year 1674. He enjoyed the benefits of an excellent education, and made so great progress in his studies, that at the age of eighteen, he obtained the degree of doctor of laws. He was, however, more attached to philosophy and the mathematics than to mere legal discussions, and applied himself most diligently to the sciences connected with or subservient to the study of astronomy. In the midst of his learned labours he found time to write poetry, and the pieces which he produced at this period, were, after the author's death, collected and published in an 8vo. volume, which has been many times reprinted. In 1698, Manfredi was nominated professor of mathematics in the university of Bologna. All the time that he was not employed in the duties of his professorship, he devoted to the study of astronomy, and in company with Victor Stancari, he spent whole nights in contemplating the heavens, and observing the motions and passages of the stars and planets. An account was published of their observations made before the year 1703. In the same year Manfredi published a treatise "On the solar Spots," and in the following season he was appointed by the senate of Bologna to the office of superintendent-general of the rivers and waters of the Bolognese. The duties of this office he conducted with a degree of skill and prudence, that proved highly beneficial to his country, and gave him a first rate reputation as a practical hydraulist. About the same time he was elected regent to the college of Monte-alto, founded by pope Sixtus V. at Bologna, for the education of young persons of his province, who were intended for the church; in this situation, which was thought to be unworthy of his talents, he was enabled to do much for the established religion, by sending into its service many celebrated divines, and others who sustained a conspicuous rank in the republic of letters. In the midst of his various labours, Manfredi found leisure to continue his astronomical studies, and to attend to other mathematical subjects; at the same time he corresponded with men of science in different parts of Europe, and began the composition of his famous "Ephemerides," which were afterwards published in several quarto volumes. In the year 1717, Manfredi was sent to Rome, on the subject of a dispute between the cities of Bologna and Ferrara, respecting the manner of conducting the inundations of the river Rheno into the Po. On his return home, he resumed his astronomical labours, and in 1723 had the long wished-for opportunity of observing a transit of Mercury over the sun, of which he published an account in the following year, under the title of "Congressus Mercurii de solis in Astronomia Specula Bononiensis Scientiarum Instituti," &c. In 1726 he was admitted an

associate of the Royal Academy of Sciences at Paris, to whom he sent a treatise "On the Method of determining the Figure of the Earth from the Parallax of the Moon," and another "On the Mode of defining the Solstices, by the fixed Stars." In 1729, he was elected a foreign member of the Royal Society at London. In his latter years, he employed himself in completing his "Elements of Geometry and Trigonometry," which he had formerly drawn up for the use of a young nobleman, and his "Astronomical Institutions." He died in the year 1739, when he was in the sixty-fifth year of his age. He was author of a great number of works which have not been noticed above, but the titles of which may be found in "Fabroni Vit. Italor. Doct." He had a brother Gabriel, who first introduced into the university of Bologna the study of algebra, and the new analysis, and acquired much celebrity by his treatise "De Constructione Aequationum Differentialium primi Generis," published in 1707. He died in the year 1761, at the age of eighty. Moreri.

MANFREDONIA, in *Geography*, a sea-port town of Naples, in Capitanata, seated on a bay of the Adriatic, called the "gulf of Manfredonia." King Manfred, who founded it in the year 1256, took great pains to give it permanent celebrity. Besides seeking counsel as to the place and time of building it, from the most eminent astrologers, to whom he could have access, he spared no labour or expence in the construction of it. The port was secured from storms by a pier, the ramparts were built of the most solid materials, and in the great tower was fixed a bell, of so large a size, that it might be heard over all the plains of Capitanata, to alarm the country in case of an invasion. He also took care to have it erected into an archbishopric. Notwithstanding all his precautions, it scarcely numbers 6000 inhabitants; though most of the corn exported from the province is shipped off here, and a direct trade carried on with Venice and Greece, with a view to which a lazaretto is established. Vegetables of all sorts are abundant in the vicinity of this town, and fish is plentiful and cheap; 93 miles N.E. of Naples. N. lat. 41° 42'. E. long. 51° 56'

MANFRO, a town of Africa, on the Gold Coast, near Cape Coast. The town is of an oval form, situated on the banks of a river, in a place almost inaccessible, on account of rugged rocks that surround it. The inhabitants are incessantly employed in fishing, agriculture, and making salt, which is much wanted; and many of them act as factors to the merchants of the interior parts.

MANG, a river of the county of Kerry, which rises in the mountains adjoining Cork and Limerick, and falls into Castlemain harbour, at the bottom of the great bay of Dingle, which can only admit vessels of moderate burden. The Mang, which is navigable to Castlemain, was the northern boundary of the ancient county palatine of Desmond. Beaufort.

MANG, in *Rural Economy*, a provincial word applied to signify a mash of bran, malt, or other similar substance.

MANGA, in *Gardening*. See MANGIFERA.

MANGABEY, in *Zoology*, the white eye-lid ape of Pennant. See SIMIA *Aethiops*.

MANGAGUABO, in *Geography*, a river of Brasil, which runs into the Atlantic, S. lat. 6° 56'.

MANGALA, in *Astronomy*, is the Sanskrit name of the planet Mars, and he, as in Europe, presides over Tuesday. In Indian paintings, he is represented of a deep red colour, with pink clothing, mounted sometimes on a white ram, with red legs, sometimes on a horse, and holding a lotus and a staff in his hands.

MANGALLO, in *Geography*, a town of Africa, in Querimba. S. lat. 10° 10'. E. long. 41° 20'.

MANGALLOON, a small island near the N.W. coast of Borneo. N. lat. 6° 9'. E. long. 115° 36'.

MANGALORE, a town of Hindoostan, in the Canara country, on the coast of Malabar, with a good road for vessels in the rainy season. It was ceded to Britain in 1794; 124 miles W.N.W. of Seringapatam. N. lat. 12° 50'. E. long. 74° 44'.—Also, a town of Hindoostan, in the Carnatic; 32 miles S. of Arcot.—Also, a town of Hindoostan, in the circar of Rachore; 100 miles W.S.W. of Rachore.—Also, a town of Hindoostan, in Guzerat, on the coast; 12 miles N. of Puttan Sumnaut.—Also, a town of the Carnatic; 10 miles N. of Volconda.

MANGALUM, a town of Hindoostan, in Coimbatore; 25 miles S.E. of Coimbatore.

MANGAN ISLANDS, a cluster of small islands, in the gulf of St. Laurence, near the S. coast of Labrador. N. lat. 50° 15'. W. long. 63° 40'.

MANGANADIA, a town of Hindoostan, in Cochin; 20 miles N.E. of Cochin.

MANGANESE, in *Chemistry*, an elementary oxydable body, and a metal. It may be obtained in a state of purity from any of its ores described in the next article. The native black oxyd, however, is the most convenient for affording this metallic substance. In order to obtain the oxyd free from the oxyds of other metals, the black oxyd must be dissolved in muriatic acid. Sulphuric acid being gradually added, the lime and barytes, if it contain any, will be precipitated in the state of sulphats of those earths. The solution may contain oxyds of iron and copper, besides that of manganese. Carbonat of potash being added will dissolve the manganese, but will precipitate the other oxyds. The oxyd of manganese may be afterwards precipitated by pure potash.

The above solution of the different metals may also be treated as follows. The copper may be precipitated by a clean piece of iron, and the iron be afterwards separated by the fuccinat of potash. The oxyd of manganese may at the last be separated by pure potash. The oxyd of manganese, thus separated, is in a state of powder. Let this powder be made into a paste with oil, and put into a crucible lined with charcoal, and filled up with powdered charcoal, the whole being closely covered. The crucible is now to be exposed for an hour to the intense heat of a forge fire, or a blast-furnace, on the plan of Dr. Aikin's. At the bottom of the crucible will be found small metallic grains, which are the manganese in its metallic form. For this process we are indebted to Ghan, who first succeeded in the reduction of this metal.

This metal, when pure, is of a greyish-white colour, of tolerable metallic lustre. Its specific gravity is about 6.85. It is very brittle, and in hardness little inferior to iron. Hence it is not a malleable metal. It melts at 160° Wedgewood. It is not magnetic when perfectly free from iron.

It has no perceptible taste or smell: when exposed to the air it soon loses its metallic lustre, and changes into the state of a brown powder, which ultimately becomes black. These changes are produced by its combination with oxygen, for which it possesses a stronger affinity at the common temperature than any of the metals, with the exception of the basis of the earth and alkalies. This property renders it of little or no use in the metallic state.

It combines with three doses of oxygen. The protoxyd, or first oxyd, is obtained by dissolving the black oxyd of manganese in nitric acid, adding, at the same time, some sugar or other inflammable matter, to take the excess of oxygen

MANGANESE.

oxygen from the black oxyd. The solution, by this treatment, becomes a nitrat of manganese, with an oxyd at a minimum of oxydation. On pure potash being added, the protoxyd is precipitated of a white colour. It is composed, according to Bergman, of 80 of manganese and 20 of oxygen in the 100.

This oxyd, exposed to the air, soon changes to a brown, and ultimately becomes of a black colour, by combining with more oxygen.

The second, or deuterotoxyd, is easily obtained by dissolving black oxyd in sulphuric acid with heat. A portion of oxygen gas is separated, so as to constitute this oxyd. If to the solution pure potash be added, the oxyd is precipitated of a red colour. It is composed of 74 of manganese and 26 of oxygen, from the authority of Bergman. This oxyd, like the last, attracts more oxygen from the atmosphere, and becomes black.

The black, or peroxyd of manganese, may be obtained by exposing the other oxyds to the air for some time. In a state of less purity it is found abundantly in nature, in which state it is used in bleaching linen and calico, to furnish oxygen to the muriatic acid.

When exposed to a red heat it gives out one dose of oxygen, and is converted into the second, or red oxyd. Hence its use in the chemical laboratory for furnishing oxygen gas.

It sometimes, however, contains carbonat of lime, in which case the gas obtained is liable to contain carbonic acid gas. The latter may be separated from the oxygen by passing the gas through lime water. The pure black oxyd is composed of 60 of manganese and 40 of oxygen.

The oxyds of manganese have not been examined by many chemists. We are indebted to Bergman for almost the whole of our knowledge of these compounds. If bodies combine in limited doses, according to the hypothesis of Dalton, the relative proportions of oxygen will be found incorrect. Agreeably to the proportion of the red oxyd, which is 26 per cent. Dalton fixes the atom of manganese at 40, the oxygen being 7. Hence, for the protoxyd, we

have $\frac{40 + 7}{7} = \frac{100}{15}$, or nearly 15 per cent. of oxygen.

For the second oxygen we have $\frac{40 + 2 \times 7}{2 \times 7} = \frac{54}{14}$, or 26 per cent. agreeably to the authority of Bergman.

The black, or peroxyd, from the same data, will be $\frac{40 + 3 \times 7}{3 \times 7} = \frac{100}{34.4}$, or 34.4 per cent. Hence it would appear that the protoxyd and the peroxyds are a little overrated.

The black oxyd of manganese is used in the manufacture of flint glass, along with the oxyd of lead, to render the glass colourless. The oxyd of manganese alone would give to the glass a purple colour, while the lead would render it of a yellow colour. In certain proportions, however, they produce no colour. May not this arise from the mixture of the three primitive colours constituting whiteness, namely, the purple, or blue and red, of the manganese, with the yellow of the lead?

If this effect depended upon the oxygen of the manganese, to which it has by some been attributed, the glass ought to be more coloured, from the oxyd of lead being more coloured in proportion to the oxygen it contains.

The black oxyd of manganese, when mixed with drying oil to form paint, causes spontaneous inflammation.

Manganese does not combine with hydrogen, nor, in all probability, with carbon.

The metal does not, according to Bergman, combine with sulphur. The same chemist, however, succeeded in combining its oxyd with sulphur, forming a sulphuretted oxyd. It is of a green colour, and affords sulphuretted hydrogen by treating with acids. There is strong reason to believe that sulphuret of manganese may be formed, since a native sulphuret has been found.

Phosphorus combines with manganese, forming a crystalline, brittle, white substance, which is not decomposed at the common temperature.

It is more fusible than manganese, but at this heat the phosphorus burns, and the manganese combines with the oxygen of the atmosphere.

Manganese combines with some of the metals, forming alloys.

Mr. Hatchett succeeded in alloying manganese with gold by the following process. The black oxyd was frequently heated with oil, till the oil inflamed. By this means the oxyd was partly reduced. This substance was introduced, with some gold, into a crucible lined with charcoal, and closely covered; a strong heat was applied. The gold by this means combined with some of the manganese, forming an alloy of a yellowish-grey colour. It was very hard, and susceptible of a good polish.

This alloy contained from $\frac{1}{5}$ th to $\frac{1}{4}$ th of manganese. The gold could be separated by cupellation.

Manganese does not combine with mercury; it combines with copper, forming an alloy of a red colour, which is malleable.

It combines with iron with great facility, and is often a component part of iron, made from iron ores containing manganese. It is said to be essential to the formation of steel, and that no iron can be used for making steel but such as contains manganese. This, however, is very doubtful. The alloys of manganese with bismuth and antimony are difficult to form, and of no importance.

Salts of Manganese.—Although the oxyd of manganese combines with the acids like the rest of the metallic oxyds, the properties of most of these compounds have not been attended to by chemists.

Sulphat of Manganese.—When dilute sulphuric acid is applied to this metal the water is decomposed, hydrogen gas is evolved, and the acid combines with oxyd, forming a sulphat of manganese. The solution of this salt is colourless; it affords crystals by evaporation of a rhomboidal form. It has a bitter disagreeable taste: when exposed to strong heat the acid escapes.

This salt consists of the protoxyd united with the acid; and agreeably to the hypothesis of Dalton, the atom of acid being 34, and the oxyd 40 + 7, the composition of the

salt ought to be $\frac{40 + 7 + 34}{34} = \frac{100}{42}$, which gives 100;

42 of acid and 58 of white oxyd.

Oxy-sulphat of Manganese.—This salt consists of the red oxyd of manganese combined with the acid.

It may be formed by distilling a mixture of sulphuric acid with the black oxyd. A quantity of oxygen gas comes over, and a liquid of a purple colour, which is water, containing the oxy-sulphat. When evaporated it affords a glutinous mass, which gives some crystals with difficulty. When an alkali is added, the red oxyd is precipitated. This salt, from the

above

MANGANESE.

above data, supposing it to be neutral, should be composed as follows, $\frac{40 + 2 \times 7 + 34}{34}$, which gives 38.6 acid, and 61.4 red oxyd. The way in which this salt is prepared, renders it probable that it is super-salt, a sub-salt being left in the retort.

The super-salt will be, therefore, $\frac{40 + 2 \times 7 + 34 \times 2}{34 \times 2}$
 $= \frac{100}{55.74}$, or 55.74 acid, and 44.26 of red oxyd. The

sub-salt would be $\frac{(40 + 2 \times 7) \times 2 + 34}{34} = \frac{100}{24}$, or 24 acid, and 76 red oxyd. The sulphurous acid added to the black oxyd is converted into the sulphuric acid, and dissolves the remaining oxyd forming the sulphat.

Nitrat of Manganese.—When the metal is added to dilute nitric acid, fumes of nitrous gas, mixed with nitrogen, and, perhaps, the nitrous oxyd, are disengaged, arising from the decomposition of part of the acid, while the remaining acid dissolves the oxyd forming the salt in question. It may also be formed by adding the black oxyd to the acid, at the same time adding some sugar to take up the excess of oxygen, which the black oxyd contains above that of the white. Carbonic acid gas is, in consequence, evolved, and the white oxyd is dissolved.

The solution of this salt is colourless; it does not afford crystals by evaporation. If the heat be continued to dryness the salt is decomposed, the acid being separated.

Its component parts, supposing it a super-salt, will be $\frac{40 + 7 + 19 \times 2}{19 \times 2} = \frac{100}{44.7}$, or 44.7 acid, and 55.3 white oxyd.

Muriat of Manganese.—The muriatic acid being added to the metal affords hydrogen from the decomposition of the water, while the oxyd is dissolved forming this salt. It consists of the acid combined with the white oxyd.

When the black oxyd is digested in muriatic acid, one part of the acid combines with the excess of oxygen in this oxyd, forming the oxymuriatic acid, which escapes in the gaseous form: the remainder of the acid unites with the white oxyd. Of this salt there is little known; it is difficult of crystallization, and is deliquescent.

When the muriatic acid is added to black oxyd in the cold, a red solution is formed, consisting of the red oxyd with the acid, and which is an oxymuriat of manganese.

The muriat may, in all likelihood, consist of $\frac{40 + 7 + 22}{22}$
 $= \frac{100}{32}$, or 32 and 67 base.

Phosphat of Manganese.—This salt may be formed by adding phosphat of soda to a soluble manganese salt. A white powder falls down, which is phosphat of manganese. It is, therefore, insoluble, or nearly so.

Fluats and borats of manganese may be formed by a similar process to the last: but these salts have not been examined.

Carbonat of Manganese.—This salt is more soluble than most of the metallic carbonats. In precipitating metallic oxyds from their solutions where manganese is contained by the alkaline carbonats, the latter oxyd is held in solution by the carbonic acid. This affords a ready method of separating manganese from most other oxyds.

Oxalic acid combines with the oxyd of manganese, forming a salt in a state of insoluble white powder.

Tartarat of Manganese.—Tartaric acid added to the black oxyd of manganese, is partly decomposed by heat. The carbon of the acid combines with excess of oxygen in the oxyd. The remaining acid afterwards dissolves the reduced oxyd. On the citric acid it has a similar effect.

Scheele informs us, that the arsenic acid dissolves the white oxyd of manganese, forming a salt which affords crystals.

The succinic acid forms a soluble salt with the white oxyd. The succinat of potash has, in consequence, been employed to separate manganese from iron, the succinat of the salts being insoluble.

The rest of the salts of this metal are not known.

MANGANESE. The ores of this metal may be divided into the following species: 1. Grey manganese; 2. Black manganese; 3. Red manganese; 4. Sulphuret of manganese; and 5. Phosphat of manganese.

1. *The grey manganese ore* is subdivided into the *radiated, foliated, compact, and earthy.*

1. *Radiated grey manganese*; *Strahliges graubraunstein-ertz*, Wern.; *Striated grey manganese ore*, Kirw.; *Manganese oxide métalloïde gris*, Haüy.; *Manganese métalloïde chalybin*, Brongn.

Colour dark steel-grey, passing into iron black; sometimes with variegated tarnish. It occurs massive, disseminated, and crystallized.

The primitive form of the crystals is the four-sided rhomboidal prism, with edges of about 100° and 80°, according to Haüy; but of 115° and 65°, according to Hauffmann's measurement. It is divisible in the direction of its six planes; and, according to Haüy, also in that of the short diagonal of the terminal planes; which latter is considered as erroneous by Hauffmann; who, therefore, pronounces the form of the integrant molecule to be the same as that of the primitive crystal.

Its most remarkable secondary forms are:

A. The rectangular four-sided prism.

B. The oblique four-sided prism (being the primitive form).

a. Summits truncated; plane of truncation straight.

b. Truncated obliquely at the summits: the plane of truncation either on one of the obtuse, or on one of the acute lateral edges of the prism. The truncation is sometimes produced by two planes placed on two adjoining lateral planes.

c. Acuminated; the acuminating planes placed either on the obtuse lateral edges (edge of acumination = 94° 7' 6"), or on the acute lateral edges (edge of acumination 118° 40' 36"). The planes of acumination sometimes again truncated.

d. Acuminated by four planes; the acuminating planes placed either on the lateral edges (with summit sometimes truncated), or on the lateral planes. (Inclination of the acuminating on the lateral planes = 118° 53' 6".)

C. The six-sided prism. (Two opposite, primitive, lateral edges = 65°, the four others = 147° 30'.)

a. Summits truncated; plane of truncation straight or flat.

b. Acuminated by two planes placed on the secondary lateral planes; at the other solid angles more or less truncated.

D. The eight-sided prism (with two lateral edges of 115°; two others of 124° 45' 46"; and four of 150° 7' 7".)

a. Summits truncated; plane of truncation straight.

b. Obliquely

MANGANESE.

b. Obliquely truncated by two pentagonal planes.

c. Acuminated by four planes placed on the most obtuse lateral edges.

d. Acuminated by six planes, four of which are placed on the obtuse lateral edges, while the two others are placed either on the lateral edges of $124^{\circ} 45' 46''$, or on those of 115° .

e. Acuminated by eight planes placed on the lateral planes.

The crystals are generally aggregated and grown together in all directions; they sometimes form globular aggregations. Their size varies, but they are seldom found exceeding one inch in length; and the generality of them are very small. Upon the whole it may be said, that their thickness is at least four times exceeded by their length; while in the *foliated manganese* both dimensions generally approach more to equality. The greatest relative length we find in the six-sided prismatic crystals, which sometimes are of a lanceolate shape, the breadth of the two secondary planes often increasing to such a degree, that but little remains of the four primitive planes.

By the union of several prismatic crystals of equal length, a particular kind of prismatic aggregations is frequently produced, having six, eight, or more lateral planes. They might be mistaken for simple crystals, from which, however, they are easily distinguishable; 1. By their lateral planes seldom forming sharp edges with one another, and being moreover always furnished with striæ, and even deep furrows; and 2. By their acuminating facets never exhibiting continued planes, but only transversal sections intercepted by interstices left by the aggregated prisms, which are in close contact with each other.

The planes of the crystals are splendid, the primitive ones eminently so; the secondary planes are always longitudinally striated. The surfaces of cleavage and fracture vary between shining and glistening; the lustre is metallic. Yields a dull iron black streak. It is opaque.

The texture of this ore is radiated, passing on one side into coarse fibrous, on the other into foliated. The amorphous, massive, and disseminated radiated grey manganese sometimes exhibits transversal fissures in the radii, in the direction of the terminal planes of the nucleus.

Fracture uneven, frequently displaying small granular masses, approaching to wedge-shaped. Fragments wedge-shaped, and long splintery; in the massive they are indeterminate angular and blunt-edged.

It is soft, brittle, and in large pieces pretty difficultly frangible. It soils strongly when rubbed.

Specific gravity 3.530—4.325, Muschenbroeck; 4.143, Hagen; 4.2491—4.7563, Brissou; 4.181, Rinmann.

According to the analyses given of the radiated grey manganese ore, by Klaproth, 100 parts afforded

	From Ihlefeld.	From Moravia.
Brown oxyd of manganese	90.50	89.
Water	7.	0.5
Oxygen gas	2.25	10.25
	99.75	99.75

Klapr.-Beitr. ij.

This ore is found principally at Ihlefeld, on the Hartz; in Saxony, at Langeberg, Johangeorgentadt, Kamsdorf, Ilmenau, Salfeld in Thuringia; in Silesia, at Konradswaldau, Kupferberg, &c.; in Bohemia, at Mies, Platten; in the Bannat; in Carinthia, at Hüttenberg; on mount St. Gothard; in Piemont and Ischia, in the Vicentine territory; in various parts of Great Britain, in Cornwall, Devonshire,

Somersetshire, Derbyshire; and also near Aberdeen, in Scotland. Jamefon.

The radiated grey manganese ore of Ihlefeld occurs partly in veins, and partly as nodules, in clay-porphry: it is accompanied with flesh-red barytes, usually crystallized in their hexangular tables with flesh-red or white rhomboidal calcareous spar, compact and foliated black manganese, and with friable lithomarge of a rose-red colour. Hauffmann in Mohr's Archiv. 1st b. p. 32.

2. *Foliated grey manganese ore; blättriges grau-braunstein-ertz*, Wern. (var. of *Manganese oxyde métalloïde gris*, Haüy.)

Its colour is the same as that of the preceding sub-species; it sometimes in a strong light appears iridescent.

It occurs massive, disseminated, and as covering of other ores. Also crystallized in four-sided, rectangular, and rhomboidal prisms, whose planes are nearly equal to each other; and in low six-sided prisms, with lateral planes either of the same breadth, or with secondary planes encroaching on the primitive, and thus producing rectangular tables, sometimes bevelled at two opposite sides, sometimes rounded off: if rounded off in the whole of their circumference, the tabular passes into the lenticular form.

The crystals are generally globularly or botroidally aggregated, and often form the uppermost covering in drusy cavities formed of black iron-stone, and lined by compact black, and amorphous foliated grey manganese ore. The oblique four-sided prisms are sometimes so intimately united, as to display no more of their surface than a three-planed solid angle, formed by a terminating and two lateral planes. The crystals are always very small; the magnifying glass discovers their lateral planes to be striated; the terminating planes are smooth.

The lustre of the surface of the crystals and of the cleavage is metallic splendid; that of the cross fracture less so.

The texture of this ore is imperfect, and mostly straight foliated, often delicately streaked, and passing over into radiated.

Fracture uneven, sometimes exhibiting fine granular distinct concretions. Fragments indeterminate angular, blunt-edged.

It is soft, and brittle. It marks strongly when rubbed. Yields a black dull streak. Specific gravity 3.742, Hagen.

The foliated grey manganese ore is found in several places with the preceding sub-species, to which it is, indeed, very nearly related. It formerly occurred plentifully in the mine St. Joachim, at Zellerfeld, on the Hartz, as coating of the drusy cavities in black and brown iron-stone, as also on quartz, &c. Hauffmann, loc. cit.

3. *Compact grey manganese ore; Dichtes grau-braunstein-ertz*, Wern.; *Indurated grey ore of manganese*, Kirw.

Its colour is bluish-black, passing into steel-grey; that of the streak iron black; in a state of incipient decomposition it takes a rust-brown hue. In a strong light its surface is iridescent.

It is found massive, and in botroidal masses, formed by the union of many globular distinct concretions. They are sometimes confluent, when they form concentric, flat conchoidal distinct layers. The globules (at least in the variety from Hertzberg, described by Hauffmann) are divergently radiated towards the centre; but towards the circumference, the radiated passes through fibrous and granular into perfectly compact. The flat conchoidal layers approach to the columnar, and here and there to the fascicularly diverging radiated structure, which again passes into compact.

Fracture even, very fine-grained, sometimes inclining to flat

MANGANESE.

flat conchoidal. Fragments indeterminately angular, not very sharp-edged.

It is hard, brittle, easily frangible. It soils less than the preceding sub-species.

Internally it is either matt, *i. e.* dull, or glistening with a metallic lustre; streak generally shining.

Specific gravity 4.125, Hauffmann.

According to an analysis of Mr. Hauffmann, it contains

Brownish black oxyd of manganese	-	-	85
Silica	-	-	4
Oxygen	-	-	11
			—
			100
			—

The compact manganese of Romaneche, near Macon, in France. (which is remarkable for its considerable hardness, and in which barytes appears to be chemically combined with the metallic oxyd,) is, according to Vauquelin, composed of

Yellow oxyd of manganese	-	-	50
Barytes	-	-	14.7
Silicx	-	-	1.2
Oxygen	-	-	33.7
Carbon	-	-	0.4
			—
			100.0
			—

It is found in Saxony, at Johangeorgenstadt, in the Palatinate, where it occurs with lithomarge; at the Wurzelberg, in the Hertzberg forest, on the Hartz, where it is used as flux for the reduction of a rich, but very refractory red hematite. Hauffmann, loc. cit.

In France it is found at Suquet, near Thiviez, department of Dordogne, in the neighbourhood of Perigueux. This is known by the name of *Pierre de Périgueux*. Also at P'aveline, near Saint-Diez, department of the Vosges; at Macon; at St. Micaud, department of the Saône and Loire. Brongn.

4. *Earthy grey manganese ore; Erdeses grau-braunsteinertz*, Wern; *Ochre of manganese*, Kirw.

Its colour varies between steel-grey and brownish-black.

Commonly massive or disseminated, sometimes superficial and dendritic.

Internally it is matt, or glimmering with metallic lustre.

Fracture earthy, fine-grained; sometimes fine scaly; fragments indeterminately angular, blunt-edged.

It soils strongly, is very tender, and meagre to the touch.

It is found in Saxony, at Raschau, Ilmenau, Ehrenstock, &c. in Bohemia, in Cornwall and Somersetshire.

Brongniart refers to the earthy grey manganese that of Saint-Jean de Gardonenque in the Cevennes. It is very light and friable, and separates, like basalt, into irregular prisms. It occurs in granite.

Lenz, Wiedemann, and other authors, class with this sub-species, the *black wad* of Derbyshire and Devonshire, which is also known under the name of *inflammable manganese*, on account of the property it possesses of inflaming spontaneously, when mixed with one-fourth of its weight of linseed oil. It consists, according to the analysis of Wedgewood, of 0.43 manganese, 0.43 iron, and 0.04 lead. Werner first made a distinct sub-species of it. According to other mineralogists, it is a variety of the black earthy manganese ore, (which see below.)

The *frothy manganese* (*Braunstein-schaum* of Wieden-

mann and others, *Manganese oxyde argentin*, Haüy,) appears likewise to be related to this sub-species; but some dark coloured varieties have been referred to the black earthy manganese ore. They require to be subjected to closer examination.

II. *Black manganese ore; Schwartz braunstein-ertz*, Wern. This is not subdivided by Werner; but Karsten, (in the new edition of his *Mineralogische Tabellen*.) and Reufs (*Mineralogie*, v. p. 463.) distinguish the *indurated* and the *friable black manganese ores*. Hauffmann, in his description of the manganese ores from Ihlefeld, adds another, namely, the *foliated*, dividing the species, in the same manner as the grey manganese ore, into three sub-species. Jameson gives the following Wernerian description of the black manganese ore.

Its colour is intermediate between brownish-black and dark greyish-black.

Occurs massive, disseminated, and in octahedral crystals, which are small, and very small. The surface of the crystals is smooth and shining.

Fracture imperfect foliated, single cleavage; sometimes it inclines to uneven, and is also small and scopiform, diverging radiated. Fragments indeterminately angular, blunt-edged.

Occurs in small and fine granular distinct concretions. It is opaque. Gives a reddish-brown streak. Is semi-hard, brittle, heavy.

It is found at Ehrenstock, near Ilmenau, on grey antimony ore. Also at Rabenstein, in Bavaria; at Zuhrbach, near Wagrain, in Salzburg; and at Miedzian, or Gora, in West Gallicia.

The *foliated black manganese ore* of Hauffmann was discovered at Ihlefeld by this distinguished mineralogist, and first described by him in the seventh edition of Blumenbach's "Handbuch der Naturgeschichte."

Its colour is coal black, approaching to a footy brown when passing into decomposition. The powder is of an iron black colour.

It is found in curved lamellar layers of from $\frac{1}{4}$ th to three lines in thickness, traversing, in connection with compact black manganese ore, the clay-porphry, which contains the veins of manganese ores in that district.

Its texture in one direction is imperfectly foliated; commonly straight, seldom curved foliated.

Fracture uneven, of a fine grain. Fragments indeterminately angular, and not very sharp-edged.

The surface of cleavage is semi-metallic, shining; that of the fracture is dull, or at best faintly glimmering, streak shining. It is opaque. Semi-hard; rather brittle. Specific gravity from 3.7142—3.800.

The foliated black manganese ore is infusible before the blowpipe; but with borax it melts into a purplish enamel. It strongly effervesces with the mineral acids, and is precipitated by caustic alkalies, as brown, by carbonic acid, as white oxyd of manganese.

It has a near oryctognostic relationship to the manganese blende of Transylvania, from which, however, it is easily distinguishable, both by its chemical properties, and by colour and streak. By decomposition it passes into the compact black manganese ore.

It is accompanied with radiated grey manganese ore, compact black and red manganese ores, with calcareous spar, and lithomarge of a rose red colour.

The *compact black manganese ore* of Hauffmann is divided into *indurated* and *friable*.

The *indurated* variety is of a deep black colour; that of the powder is a footy or brownish-black.

It

MANGANESE.

It is found massive, and in thin curved lamellar layers. It is dull; streak shining or glimmering.

Fracture fine earthy; fragments indeterminately angular, blunt-edged. It is soft; foils strongly; feels meagre, and adheres to the tongue.

It has been found in St. Joachim mine, Zellerfeld (the massive), and at Ilhefeld, where it traverses clay-porphry in all its directions. It is accompanied by foliated black manganese ore, which appears to pass into it by decomposition.

The friable variety is of a black and brownish-black colour.

It is found massive, in globular masses, in thin curved lamellar distinct concretions on black hematite, often also as thin coating on black hematite, and dendritic.

Internally it is dull; the surfaces of the lamellar distinct concretions sometimes glimmering; streak shining.

Fracture fine earthy, fragments indeterminately angular, blunt-edged. It is perfectly friable; foils strongly, feels meagre, and adheres strongly to the tongue.

The variety from Huthal, or the Hartz, was analysed by Klaproth with the following result:

Brown oxyd of manganese	68
Oxyd of iron	6.50
Carbon	1
Barytes	1
Silica	8
Water	17.50
	102.0

It is found on the Hartz at the Iberg, at Zellerfeld, at the Galgenberg, near Clauthal, and in the Huthal, on the Hartz, where, according to Klaproth, it was found issuing from the chinks of rocks as a moist, greasy substance, which, on being exposed to the air, was soon converted into a very fine black powder.

The finest dendritic varieties, from the Hartz, are those of Grund, on a greyish-white marle-slate; and those of Lerbach, on a green clay-slate.

Reufs, who describes the friable black manganese ore, refers to it the *wad*, mentioned above as a variety of the earthy grey manganese ore. It is, indeed, difficult to determine to which of the two the English black wad belongs, the different varieties of which require to be subjected to further examination.

Another substance nearly related to the wad is the *frothy manganese*, a metallic, reddish-brown, filmy substance, incrusting black hematite, and referred by some mineralogists to iron froth, by others to the earthy grey manganese.

III. *Red manganese ore*; *Rother braunstein*, Werner; *Manganèse silicifère blanc et rose*, Haüy; *Manganèse tithoïde blanc et rouge*, Brongn.

Its colour is rose red of various intensity; and sometimes a very light yellowish-brown.

It occurs massive and disseminated.

Internally it is dull.

Fracture even, passing into large and flat conchoidal, and also sometimes into splintery fragments: indeterminately angular, pretty sharp-edged.

It is slightly translucent, hard enough to scratch glass; brittle, and easily frangible.

Specific gravity 3.233, Kirwan, that of the Siberian 3.676, Lampadius.

Is infusible before the blowpipe without addition, but assumes a brownish colour; if the flame be urged by oxygen gas, small particles will melt into a brownish-black bead.

VOL. XXII.

attractable by the magnet. The Siberian red manganese ore, analysed by Lampadius, is stated by this chemist to be fusible by the heat of the blowpipe, when continued for a few minutes, into a shining black enamel; and much more easily with borax.

According to the analysis given by Ruprecht, that from Transylvania consists of

Oxyd of manganese	35.15
Oxyd of iron	7.04
Silica	55.06
Alumine	1.56
Water	0.78
	99.59

The analysis of red manganese from Kapnik by Lampadius, appears to be that of a red variety of pearl-spar; (or perhaps of real carbonat of manganese.) The same chemist has, however, given an analysis of the red manganese fossil from Siberia, which certainly belongs to the substance under consideration, although Mr. Lampadius himself appears to be of a different opinion. The results of his analysis are

Oxyd of manganese	0.610
Oxyd of iron	0.050
Silica	0.300
Alumine	0.020
Loss	0.020
	1.000

The red manganese ore of Kapnik, which is placed by Mohs, near pearl-spar, under the name of Rothstein, is found there as part of a vein formation, together with black silver ore, (Schwartz-giltig-ertz,) brown and yellow blende, galena, quartz, and now and then with some pearl-spar. The veins containing this formation are mostly narrow, and often of a stratified structure, in such a manner that either massive quartz, or a mixture of quartz and red manganese, (Rothstein), alternate with strata of black silver ore, and blende, or galena, from the sides towards the centre of the vein, where the druses are generally incrustated with crystallized quartz, or also with pearl-spar. This, according to Mohs, is the general nature of those veins, which however, also contain other fossils besides.

IV. *Sulphuret of manganese*; *Braunstein blende*; *Mangan-glanz*; Karst; *Schwartz*, Klapr. Reufs.

Its colour is between iron and pitch-black, here and there with a rust-coloured covering, often with variegated tarnish. Colour of the powder dark brass-yellow passing into greenish.

It is found massive, or coarsely disseminated in red manganese ore, which it also traverses in foliated layers.

Texture in one direction imperfectly foliated; direction of the folia approaching to curved foliated. According to Haüy it is divisible into a rhomboidal prism, which may be subdivided in the direction of the diagonals of its transversal section.

It is opaque; its lustre is semi-metallic shining; the rust-coloured decomposing parts dull; streak shining.

Fracture fine-grained uneven; fragments indeterminately angular, not particularly sharp-edged.

It is soft, mild, and not difficultly frangible. Specific gravity 3.950. Klapr.

Infusible before the blowpipe. When pulverized it gives out sulphureted hydrogen as the addition of nitrous acid.

According to Klapproth's analysis, it consists of

Oxyd of manganese	-	-	-	82
Carbonic acid	-	-	-	5
Sulphur	-	-	-	11
				—
				98
				—

Klapr. Beitr. 3.

Vauquelin is of opinion, that the carbonic acid in the preceding analysis belongs to the matrix of this ore. According to this chemist the constituents are: manganese at the minimum of oxydation 85, and sulphur 15.

It is found in Transylvania, in red manganese ore accompanied with black tellurium, red and brown blende (sulphuret of zinc), copper pyrites, &c.

According to Delrio it has also been lately found in Mexico.

V. *Phosphat of manganese; Phosphor-mangan*, Karst.; *Eisen-pech erz*, Wern.; *Manganese phosphaté (ferrifère)*, Haüy.

Its colour is reddish and blackish-brown, which passes into black; colour of the streak greyish, yellowish, or reddish-brown.

It occurs massive. According to Haüy it is divisible in the direction of planes, which appear to indicate a rectangular parallelepipedon for the nucleus.

Internally it is shining and glistening, with a resinous lustre.

Fracture flat and imperfectly conchoidal, passing into fine-grained uneven; fragments indeterminate angular.

It is faintly translucent at the edges.

It is semihard, passing into soft; brittle.

Specific gravity 3.95.

It is readily fusible before the blowpipe into a black enamel; and is entirely soluble in nitric acid without effervescence.

It is seldom found pure, generally containing iron, which, however, according to Darcet, appears to be accidental; the phosphoric acid being probably combined with the manganese alone.

The light coloured varieties contain but a small quantity of iron.

Vauquelin, who analysed this ore, obtained the following result:

Oxyd of manganese	-	-	-	42
Oxyd of iron	-	-	-	31
Phosphoric acid	-	-	-	27

Journ. des Mines.

It has hitherto been found only near Limoges in France; it occurs in granite, in the same veins that contain the well known opaque beryl.

MANGANUM, *Μαγνησιον*, among the Greeks, a general name for instruments to throw large stones with.

MANGATTI, in *Geography*, a town of Hindoostan, in Travancore; 18 miles N.E. of Anjenga.

MANGAVEIRAS, a town of Brasil, in the government of Para; 35 miles N.E. of Engenhoreal.

MANGA-BOONG, a town on the N.W. coast of Borneo. N. lat. 6° 3'. E. long. 116° 9'.

MANGART, THOMAS, in *Biography*, a learned monk, who obtained a very high reputation by his knowledge, and was appointed antiquary, librarian, and counsellor to duke Charles of Lorraine. He died in 1763, and is known in the republic of letters for a work entitled

"Introduction à la Science des Medailles," fol. This work contains all the principles laid down in the elementary treatises on the numismatic science, and serves as a supplement to the "Antiquité expliquée" of Montfaucon.

MANGEE, in *Geography*, a town of Hindoostan, in Bahar; 13 miles W.N.W. of Chupra.

MANGEEA, or MANGYA, an island in the South Pacific ocean, discovered by captain Cook in the year 1777; but on which he could find neither a landing place nor anchorage. Such parts as fell under our navigator's observation were guarded by a reef of coral rock, on the outside of which the sea is of an unfathomable depth. It is full five leagues in circuit, and of a moderate and pretty equal height; though, in clear weather, it may be seen at the distance of ten leagues. In the middle it rises into little hills, from which there is a gentle descent to the shore, which, at the S.W. part, is steep, though not above 10 or 12 feet high, and has several excavations made by the beating of the waves against a brownish sand-stone of which it is composed. The descent is covered with trees of a deep green colour, very thick, but not high, seeming to be of the same sort, except near the shore, where are many of that species of dracena found in the woods of New Zealand. On the N.W. part the shore terminates in a sandy beach, beyond which the land is broken down into small chafms or gullies, and has a broad border of trees resembling tall willows. Farther on the ascent, the trees were of the deep green above-mentioned; and were supposed by some to be the rima, intermixed with low cocoa-palms, and a few of some other sorts. On the little hills were trees of a taller sort, thinly scattered; but the other parts were bare, and of a reddish colour, or covered with something like fern. Upon the whole Cook observes, that the island has a pretty aspect, and might be made a beautiful spot by cultivation. When this island was first discovered, several of the natives were observed to be armed with long spears and clubs, which they brandished in the air either with signs of threatenings, or, as some thought, with invitations to land. Most of them appeared naked, except having a sort of girdle, which passing between the thighs covered that part of the body. Some of them, however, had pieces of cloth of different colours, which they wore as a garment, thrown over their shoulders; and almost all of them had a white wrapper about their heads, not much unlike a turban, or like a high conical cap. Their colour was tawny, and they were in general of a middling stature, but robust and inclining to corpulence. They were at first afraid of approaching the ship in their canoe; but being addressed by Omai in the Otaheitean language, their apprehensions subsided, and they came near enough to take some beads and nails, which were thrown into their canoe. They were at first afraid of touching these things, which probably arose from superstition; for Omai understood, that when presents were offered them, they asked something for their "Eatooa," or god. When they were asked, if they ever ate human flesh; they answered in the negative, with a mixture of indignation and abhorrence. They wore a kind of sandals, made of a grassy substance interwoven, probably to defend their feet against the rough coral rock on the shore. Their beards were long; and the inside of their arms, from the shoulder to the elbow, and some other parts, were punctured or tattooed, like the inhabitants of almost all the other islands in the South sea. The lobes of their ears were pierced, or slit, to such a length, that one of them stuck there a knife and some beads which had been given him; and the same person had two polished pearl-shells and a bunch of human hair, loosely twisted, hanging about his neck,

neck, which was the only ornament that was observed. The only canoe, that was seen, was not above 10 feet long, and very narrow, but both strong and neatly made. As the inhabitants seemed to be numerous and well fed, such articles of provision as the island produces must be very plentiful. One of the islanders who came on board informed our navigators, that they had no animals, as hogs and dogs, both which they had heard of; but acknowledged that they had plantains, bread fruit, and taro. The only birds that were seen were some white egg-birds, terns, and noddies; and one white heron on the shore. The language of the inhabitants of Manglea is a dialect of that spoken at Otaheite; though their pronunciation, like that of the New Zealanders, be more guttural. The natives of Manglea seem to resemble those of Otaheite and the Marquesas in the beauty of their persons, more than those of any other nation seen by Capt. Cook in those seas; having a smooth skin and not being muscular. Their general disposition also corresponds with that which distinguishes the first mentioned people; for they are not only cheerful, but are acquainted with all the lascivious gesticulations which are practised by the Otaheiteans in their dances. Their houses also seem to resemble those of Otaheite. They salute strangers much after the manner of the New Zealanders, by joining noses; adding, however, the ceremony of taking the hand of the person to whom they are paying civilities, and rubbing it with a degree of force upon their nose and mouth. Cook's Third Voyage, vol. i.

MANGEL WURZEL, in *Agriculture*, a plant of the tap-rooted kind, which has been lately introduced into field culture. It is a variety of the common beet. The author of a late work on husbandry remarks, that it grows to a large size, both in the root and top, the former being of a reddish cast, and the leaves in the latter of an oblong form, extremely thick, fleshy, and succulent. Mr. Young, however, observes, that it is but little in cultivation at present; though in Norfolk, sir Mordaunt Martin finds the root advantageous for his cow stock. The leaves are asserted to be "equal in quality to spinach, and from their frequently extending in length more than thirty inches, and in breadth above twenty, to greatly exceed that vegetable in point of produce."

Soil.—This, like all other tap-rooted plants that have been employed for the purposes of husbandry, thrives the best in soils of the deep, friable, sandy, or light loamy descriptions.

Preparation.—In preparing the ground for its reception, it is necessary to render it as deep and fine as possible in the mould. This may be best effected in the heavier sorts of land, by means of trench ploughing, in the manner of that for parsnips; and in those of the lighter kind, by repeated common deep ploughings. In both cases, the frequent use of the harrows will be requisite. A proportion of good manure should also be turned in, so as to render the ground sufficiently rich for the perfect growth of the plants. After this, at the time of putting in the seed, the land should be thrown into two-bout ridges, which leaves the tops about two feet in breadth, and the furrows one. In this way a considerable increase in the depth of mould is provided for the roots of the plants. And in soils that are in some measure retentive of moisture, the lands are kept much drier, and in a state more fit for the growth of the plants.

Seed and Method of sowing.—It is advised, that the seed should be carefully selected from such plants as are the most perfect of their kind, and that have been cultivated at a distance from other varieties. It should have arrived at a

full state of ripeness, and be made use of while fresh. The most proper season for putting the seed into the ground in the common method of sowing, is in the early part of the spring as soon as the season will admit, as in the beginning or middle of April; but where the transplanting method is intended, it should be sown much earlier and very thinly, as the beginning of March, in order that the plants may be in a state to be set out.

The most common method, where the surface of the land is flat, is to sow the seed thinly over the ground, in the manner that is practised for carrots, covering the seed in by means of very light harrowing. In this way, the plants are afterwards set out by the hoe to proper distances. But where the land is raised into ridges in the manner just described, another mode is practised: the seed is dropped singly by the hand into little holes made by a dibble, to the depth of about half an inch, all along the middle of them, at the distance of eight or nine inches from each other; the plants thus standing at the distance of three feet, from row to row, and eight or nine inches apart in them. But as it is not necessary that they should stand nearer than 16 or 18 inches, every other plant may be removed, and used for filling up vacancies, where they occur, or if not wanted in that way, wholly removed by the hoe. In this mode the intervals can be kept perfectly clean by the plough or horse-hoe, and the rows by hand-hoeing.

In the practice of transplanting, the plants should be removed, when not more than three or four inches in length, and be planted out in rows upon ridges prepared as above at the distance of 18 inches each way. In performing the work, the holes should be made sufficiently deep to admit the roots without their being bent. The tops of the plants may be taken off before planting, but the roots should not be touched, nor should they be put in too deep. A rather moist season should be chosen, if possible, for this business. But though the plants grow well in this method, the roots seldom become so large as when they have remained in their original situation.

All the culture that is afterwards necessary in this sort of crop, is to set out the plants to proper distances, where put in, in the first methods, and keep them clear from weeds by one or more hoeings, according to the manner of sowing that may have been practised, and other circumstances.

It has been stated that the application of this vegetable "has been chiefly in the feeding of neat cattle and hogs; in which both the tops and roots have been employed, but without that success which might have been expected from the manner in which it was brought to the notice of cultivators." It is probable, that upon the whole, the root has neither been found to be equal in quality as a cattle food, or to afford the quantity of produce that was supposed upon its first introduction, but from its being of a hardy nature, and not liable to be injured, either by insects or the effects of drought, as well as from its leaves being capable of being repeatedly cut over, it may be occasionally cultivated in situations where green food is much wanted in the latter end of the year, for milch cows or other sorts of live stock.

In some trials detailed in the *Annals of Agriculture*, the plants seem, however, to have afforded a large produce in leaves, when gathered every two or three days, from July till late in September; others have not found the whole produce, in leaves and roots, equal to that of the large cabbage, on the same kinds of soil, while the culture was considerably more troublesome and expensive, and the crop not so useful for the purpose of winter consumption.

In the trials of an ingenious cultivator, as stated in the Bath Papers, the tops were found to be eaten with much greediness by cows, calves, and hogs, when cut green, during the latter part of the summer and in autumn, but the roots were almost wholly rejected at these periods, though in winter, after they had been taken up, they were eaten very well.

The great objections to this vegetable, as a field plant, are, according to a late writer, "the great expence of its culture, its being liable to degenerate, and the fibrous nature of the roots rendering their preparation as cattle food troublesome."

The roots frequently rise, it is said, to the weight of from five to eight or ten pounds, according to the goodness of the land; and they may be preserved in the winter, by being taken up and packed in the manner of carrots, or any other method.

MANGEN, in *Geography*, a town of the duchy of Courland; 10 miles S.W. of Piltn.

MANGER, in *Ship Building*, a place parted off immediately within the hawse-holes. It prevents whatever water that comes in at the hawse-holes from running off, and is returned back again by the scuppers in the manger.

MANGER, in *Rural Economy*, an internal part of the stable in which the corn or cut provender of the horse is put. It is a sort of box or crib, and the usual method is to have them the whole breadth of the stall; but this is unnecessary, as when eighteen or twenty inches in length, and fourteen or sixteen in breadth, they will be sufficient for every useful purpose. In the fixing of them they should be so contrived as to admit of being removed for the purpose of being cleaned. This can, however, never be done in the old method of fixing them: but, by a little contrivance, may be easily effected. It is, in many cases, a convenient plan to have them in the corners or angles at the heads of the stalls. See STABLE and STALL.

MANGERA, in *Geography*, an island of Mexico, about four miles in circumference, in the gulf of Amapalla.

MANGERA Strait, a channel of the East Indian sea, between the islands of Cumbava and Flores, full of small islands. Flores is also called Mangeray.

MANGERBARY, a town of Hindoostan, in Vissapour; 15 miles S. of Merritch.

MANGERTON, a mountain of Ireland, in the county of Kerry, S. of the lake of Killarney, and forming a very interesting object in the scenery of that beautiful and romantic spot. It is one of the highest mountains in Ireland, being 2500 feet above the lake. From its summit, the two lakes, with the passage between them, and a large tract of country, may be seen to great advantage. To ascend Mangerton should therefore be a fixed object of every person who visits Killarney.

MANGET, JOHN JAMES, in *Biography*, a laborious medical writer, was born at Geneva in June, 1652. After going through his classical studies and the courses of philosophy, he commenced the study of theology, with the intention of entering the clerical profession, but after five years of labour, his inclination to medical pursuits prevailed, and by the aid of books alone, without any teacher, he made such a progress, that he was admitted to the degree of M.D. at Valence, in Dauphiny, in 1678. He then commenced the practice of physic, in which he obtained considerable reputation in his native city, which he refused to quit, though solicited by invitations from various quarters. In 1699, Frederick III. elector of Brandenburg, and afterwards the first king of Prussia, honoured him with the appointment of his first physician. In his literary la-

bours, Manget was indefatigable, even to the end of his long life. He maintained a correspondence with many of the learned men of his time, some of whom, especially Daniel le Clerc, the author of the History of Medicine, are said to have assisted him in his works. He died at Geneva in August, 1742, in the ninety-first year of his age.

Among the numerous works of compilation, which Manget executed, originality is not to be expected; nor are they remarkable for judgment and accuracy. They are, however, still useful for reference. They are as follows: 1. "Mellis Medico-spagyrica, &c." folio, Geneva, 1683; which contains a most abundant collection of pharmaceutical preparations, arranged in a very complex order. 2. In the same year he edited, "Pauli Barbette Opera omnia Medica & Chirurgica," with additional cases and illustrations. 3. "Bibliotheca Anatomica," 1685, two vols. folio; a work which was executed in conjunction with Daniel le Clerc. He afterwards edited; 4. The "Compendium Medicinæ Practicæ," of J. And. Schmitz. 5. The "Pharmacopeia Schrodero-Hoffmanniana." 6. The "Tractatus de Febribus" of Franc. Pieus; and 7. The "Sepulchretum" of Bonetus, to which he added several remarks and histories. 8. In 1695, he published his "Bibliotheca Medico-Practica," four vols. folio; a vast collection of practical matter relative to all the diseases of the human body, arranged in alphabetical order. Other compilations of a similar kind he afterwards published relative to surgery, chemistry, and pharmacy: viz. 9. "Bibliotheca Chemica curiosa," two vols. folio, 1702; 10. "Bibliotheca Pharmaceutico-Medica," two vols. folio, 1703; and 11. "Bibliotheca Chirurgica," four vols. in two, folio, 1721. But in the mean time, he had printed his (12.) "Theatrum Anatomicum, cum Eustachii Tabulis Anatomicis," two vols. folio, 1716. This is a description of all the parts of the body, abridged from various authors; the osteology is that of Bidloo; the myology that of Brown; and the splanchnology that of Ruysch; and his selections are not to be praised. It has been justly objected to him, that he omitted to notice the discoveries of the anatomists of the sixteenth century. There is scarcely any thing of his own in this work, except some morbid dissections. On the appearance of the plague at Marseilles, he published a collection of facts and opinions on that disease, under the title of "Traité de la Peste recueilli des meilleurs Auteurs," two vols. 12mo. 1721: and, in the following year, 14. "Nouvelles Reflexions sur l'Origine, la Cause, la Propagation, les Préservatifs, et la Cure de la Peste," 12mo. 15. His "Observations sur la Maladie qui a commencé depuis quelques années à attaquer le gros Betail," was a collection of the opinions of the Genevese physicians concerning the distemper of horned cattle. The last work of Manget was his "Bibliotheca Scriptorum Medicorum veterum et recentiorum," at which he laboured when at least eighty years of age, and published it in two vols. folio, in 1731. It is the most important of his productions, being an useful collection of medical lives, and catalogues of writings. Eloy Dict. Hist. Gen. Biog.

MANGEY, THOMAS, a learned English divine, was educated at St. John's college, Cambridge; where, in due time, he took his degree of D.D. He was distinguished in the church as prebendary of Durham, and published an edition of "Philo Judæus," in 2 vols. folio: "An Answer to Toland's Nazarenus;" and a volume of "Sermons on the Lord's Prayer." He died in the year 1755.

MANGIFERA, in *Botany*, is that celebrated fruit of the East Indies called *Mango*, whose different varieties are universally known and cultivated in that country, being as much esteemed, and nearly as various in quality, as the different

different kinds of apples produced in England. The vernacular name of this fruit, which may be considered as a sort of plum, is *Manga*, or *Mangos*, and this appellation being coupled to the verb *fero*, to bear, shews the derivation of its generic name. Linn. Gen. 110. Schreb. 153. Willd. Sp. Pl. v. 1. 1150. Ait. Hort. Kew. ed. 2. v. 2. 39. Juss. 369. Lamarck Illustr. t. 138. Gærtn. t. 100.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Terebinthaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, deeply cloven into five, lanceolate segments. *Cor.* Petals five, lanceolate, furrowed, longer than the calyx. *Stam.* Filaments five, awl-shaped, spreading, as long as the corolla; anthers inclining to heart-shaped. *Pist.* Germen superior, roundish; style thread-shaped, the length of the calyx; stigma simple. *Peric.* Drupa kidney-shaped, oblong, keeled, compressed. *Seed*, an oblong, compressed, woolly nut.

Eff. Ch. Corolla of five lanceolate petals. Drupa superior, kidney-shaped. Nut woolly.

1. *M. indica*. Mango Tree. Linn. Sp. Pl. 290. Jacq. Ic. Rar. v. 2. t. 337. Andr. Bot. Repof. t. 425. (*Manga domestica*; Rumph. Amboin. v. 1. 93. t. 25.)—Leaves stalked, lanceolate-oblong. Four of the stamens abortive.—Native of the East Indies. With us it is kept in the stove, where it blossoms in spring and autumn, though rarely. In India it forms a tall and spreading tree, not unlike an oak in its manner of growth, with thick and wide-extended branches, but the wood is far more brittle and less hard and firm. *Leaves* scattered, stalked, simple, about a span long, and an inch or two wide, wavy, entire, tapering at each end, veiny, smooth and shining. *Panicles* terminal, compound, spreading, downy, of innumerable small white flowers, most of which are abortive. *Fruit* the size of a large plum, of an orange or tawny colour with a tinge of red; its pulp extremely juicy, with a rich sweet perfumed flavour, accompanied by a grateful acidity. Rumphius says it is the finest Indian fruit except the Mangostan; (see *GARCINIA*.) In an unripe state it makes an excellent pickle, often brought to Europe.

2. *M. lasiflora*. Loose-flowered Mango. Lamarck Dict. v. 3. 697. Willd. n. 2.—“Leaves ovato-lanceolate, nearly sessile. Stamens all perfect. Fruit roundish.”—Native of the island of Mauritius. We know this species merely by Lamarck’s account. It is said to have the habit of the foregoing, but the leaves are nearly sessile, the panicles more elongated and lax, the stamens all perfect, segments of the calyx much more obtuse, and the fruit smaller, more oval and rounded.

3. *M. axillaris*. Axillary-flowered Mango. Lamarck Dict. v. 3. 697. Willd. n. 3.—“Leaves ovate-oblong, bluntish. Panicles axillary. Stamens ten.”—Found by Sonnerat in the East Indies. Lamarck, who received it from that intelligent traveller, describes this species as clearly distinguishable from the two former by the above characters. The leaves are four or five inches long, and near two in breadth. *Fruit* the size of a small cherry, but that author saw it only in a dry, and possibly unripe state.

Another species is described in the *Supplementum* of Linnæus, p. 156, by the name of *M. pinnata*, but this is now referred by Willdenow to *Spondias*, and, as it seems, justly. See *SPONDIAS*.

MANGIFERA, in *Gardening*, comprehends a plant of the tree exotic kind for the stove, of which the species cultivated is the Mango-tree (*M. indica*.)

There are several varieties, none of which are cultivated.

Method of Culture.—As the vegetative property of the

seed or nuts of this species of tree does not seem to be long preserved, the readiest method to obtain plants, is to have a quantity of the nuts set in tubs of earth in the country where they grow naturally, and when the plants are grown a foot high, to have them shipped, placing a covering over them to defend them from the water and spray of the sea, being careful not to give them too much water in the passage. When they arrive in a cold climate, they should be screened from cold. The plants should afterwards be set in pots filled with light kitchen-garden earth, and be placed in a dry stove, where, in warm weather, they should have fresh air daily, and in winter the air be kept up to temperate, as marked on the botanical thermometer; as they do not succeed well in the tan-bed of the stove.

And where the nuts are made use of, they should be sent over in wax to preserve their vegetative property.

They are also capable of being increased from cuttings, in the manner of gardenia, in this climate.

MANGISCHLAK, in *Geography*, a town on the E. coast of the Caspian sea, which is a place of considerable trade between the Tartars and Russians of Astrachan; 180 miles S.E. of Astrachan. N. lat. 44° 10'. E. long. 52° 14'.

MANGIT, a town of European Turkey, in Bessarabia; 22 miles N.N.E. of Tobak.

MANGLARES, or *CORN ISLAND*, a small island in the Spanish Main, about 15 miles long and five broad; near which is another small island called “Little Manglares.” N. lat. 11° 44'. W. long. 82° 20'.

MANGLE. See *LAURACEÆ*.

MANGLE, or *Mangles*, in *Botany*. See *RHIZOPHORA*.

MANGLILLA, *J. n. 151*. A Peruvian shrub, with the habit of a *Cherry-laurel*, but with small axillary pentandrous flowers, to which Dombey gave the name of *Dubamelia*. It is called *Caballeria* in the *Flora Peruviana*. See *MYRSINE*, to which genus this plant is referred by Mr. R. Brown.

MANGNOR, in *Geography*, a town of Norway, in the province of Aggerhuus; 15 miles S. of Konigswinger.

MANGO, a town of Africa, in the kingdom of Agonna; which see.—Also, a river of Sweden, which runs into the Wenner lake; 10 miles W. of Caritadt, in the province of Warmeland.

MANGO-Tree, in *Botany*. See *MANGIFERA*.

There are various sorts of this fruit, as there are of our apples and pears, which are very different, according to the countries where they grow: that species, which is without a stone, and is very grateful to the palate, seems to us only a variety or a degenerated fruit; the fruit is cut into slices, and eaten either without wine, or macerated in wine; it is also candied, in order to its preservation; sometimes they open it with a knife, and fill up the middle with fresh ginger, garlick, mustard, and salt, with oil or vinegar, that they may eat it with rice, or after the manner of pickled olives.

As to its temperament, this fruit is cold and moist, though the Indian physicians affirm the contrary. We make use of pickled mangoes which are imported to us, as we do of pickled cucumbers. The stones roasted are said to cure a looseness, which Garcias found to be true. The wood of the tree, with cinders, is used for burning the carcasses of the Pagans, as being consecrated to this rite; whence it serves also for coffins, in which they deposit their dead; it is, however, of a soft substance, and of a short duration. The stalks supply the place of areca, or caunga, in the chewing of betel; the same, calcined and reduced to powder, take away warts. Of the tender leaves, with the bark

of the *avanacoc*, that is, the ricinus, the seed of cummin and parpaclagam, is made a decoction, which is said to be highly beneficial in the cough, asthma, and other affections of the thorax. The bark of the tree pulverized, and taken in chicken broth, is an excellent dissolvent of extravasated and coagulated blood, occasioned by a fall, in any part of the body. The juice of the bark, with the white of an egg, and a very little opium, taken inwardly, is a present remedy against the diarrhoea, dysentery, and tenesmus. Of the gum of the tree, and the flowers of rice, with the addition of a small quantity of opium and pepper, are prepared pills, which also cure all sorts of fluxes of the belly. Of the flour of the dried kernels the natives have the art of preparing various kinds of food. James.

MANGO, in *Ornithology*, a species of *Trochilus*; which see.

MANGONA, in *Military Language*, formed from a Greek word of the same import, in the time of the lower empire, was used in general to denote all kinds of machines; and *Mangonel* was a diminution, applied to the smaller machines.

MANGONEGRO, in *Geography*, a market and post-town of Spain, in the kingdom of Seville, three leagues from Cordova.

MANGONNE, one of the smaller Friendly islands. S. lat. $19^{\circ} 38'$. E. long. $185^{\circ} 30'$.

MANGOPUNGLY, a town of Hindoostan, in Meywar; 38 miles E. of Chetore.

MANGOR, a town of Africa, in the kingdom of Kayor.

MANGOSTANA, in *Botany*. See **GARCINIA**.

MANGOUSTE, in *Zoology*, *Viverra Mungo*. See **VIVERRA** and **ICHNEUMON**.

MANGRABA, in *Geography*, a town of Hindoostan; in Bahar; 55 miles N. of Hajypour.

MANGROLLA, a town of Hindoostan, in Guzerat; 25 miles N.E. of Surat.

MANGROVE, in *Botany*. See **RHIZOPHORA**.

MANGROVE Grape. See **COCCOLOBA**.

MANGROVE Island, in *Geography*, a small island among the Bahamas. N. lat. $26^{\circ} 12'$. W. long. $78^{\circ} 45'$.

MANGROVE River, a river of New Zealand, so called by lieutenant Cook in 1769, on account of the number of mangrove trees about it, which runs into Mercury bay. The safest and best way of sailing into this river is to keep the south shore all the way on the board. The country on the E. side of the river and bay is very barren, its produce being only fern, and a few other plants that will grow in a poor soil. The land on the N.W. side is covered with wood, and the soil, being much more fertile, will, doubtless, produce all the necessaries of life with proper cultivation. The inhabitants have no plantations; their canoes are mean, and without ornament; they sleep in the open air, and say, that Taratu, whose sovereignty they do not acknowledge, if he was to come among them, would kill them. Hence it was inferred, that they were outlaws; though they said that they had heppahs, or strong holds, to which they retired in time of danger. Hawkesworth's Voy. vol. ii.

MANGSCHÄTE, a town of Silesia, in the principality of Brieg; 8 miles N.E. of Brieg.

MANGULUM, a town of Hindoostan, in Coimbetore; 25 miles S.S.E. of Coimbetore.

MANGUT, a town of Hindoostan, in Baramaul; 28 miles S.S.E. of Darempoor.

MANGUTZKOI, a town of Russia, in the government of Irkutsk, on the borders of China; 88 miles W. of Doroninsk. N. lat. $49^{\circ} 40'$. E. long. $111^{\circ} 4'$.

MANHEIM, a city of Germany, now belonging to the electorate of Baden, is situated on a low plain, near the conflux of the Neckar and the Rhine. The old village and citadel of Manheim were converted into a town by the elector Frederic IV. in the year 1606, and adapted to the accommodation of some Netherlanders, who had quitted their country for the sake of liberty of conscience: and though it was afterwards, viz. in 1622, besieged and taken by the Bavarians, and again, viz. in 1688, entirely demolished by the French, it was re-built by the electors John William and Charles Philip, and fortified in such a manner, that it became one of the strongest places in Germany. Its present works were formed upon the system of Coehorn. The number of inhabitants, exclusive of the garrison, was, in 1784, 21,858. Some of the streets are planted with rows of trees, and it has five or six open places, suitable for promenades or markets. The custom-house, forming one side of these, is a noble stone-building, resembling a palace, having under the colonnades that surround it shops for jewellery and other commodities. The elector's palace opens on one side to the city, and on the other to the ramparts; it contains a gallery for paintings, and cabinets of antiquities and subjects of natural history, a library, treasury, and menage. Manheim was taken by the French in 1795, and, in 1802, it was ceded, together with its territory, to the margrave (elector) of Baden. N. lat. $49^{\circ} 28' 59''$. E. long. $8^{\circ} 27' 22''$.

MANHEIM School of Music. About the year 1759, the band of the elector palatine in this city, and at Schwetzingen, was regarded as the most complete and best disciplined in Europe. We found it to be, indeed, all that its fame had made us expect: power will naturally arise from a great number of hands; but the judicious use of that power, on all occasions, must be the consequence of good discipline; indeed, there were more solo players and good composers in this than perhaps in any other orchestra in Europe; it was an army of generals, equally fit to plan a battle as to fight it.

But it was not merely at the elector's great opera that instrumental music had been so highly cultivated and refined, but at his concerts, where this extraordinary band had full liberty to display all its powers, and to produce great effects without the impropriety of destroying the greater and more delicate beauties peculiar to vocal music; it was here that Stamitz, stimulated by the productions of Jomelli, first surpassed the bounds of common opera overtures, which had hitherto only served in the theatre as a kind of court-cryer, with an "O Yes!" in order to awaken attention and bespeak silence at the entrance of the singers. Since the discovery which the genius of Stamitz first made, every effect has been tried which such an aggregate of sound can produce; it was here that the crescendo and diminuendo had birth; and the piano, which was before chiefly used as an echo, with which it was generally synonymous, as well as the forte, were found to be musical colours which had their shades, as much as red or blue in painting.

In 1772, the band of his electoral highness consisted of near a hundred hands and voices. Among whom were Hotzbauer, Canabich, Charles and John Toefchi, Bapt. and Charles Wendling, and the late excellent performer on the violin and leader, Cramer. There were twenty-three vocal performers in this band, among whom Mad. Wendling, Mad. Danzi, afterwards married to Le Brun, a celebrated performer on the hautbois, Mad. Cramer, the mother of the present admirable performers now in England, and Allegranti; with the Italian vocal performers, Roncaglio, Pefarini, and Saporosi. His electoral highness of that period was himself a good performer on the German flute. And the operas

operas executed at Manheim in winter were represented in one of the largest and most splendid theatres in Europe, capable of containing 5000 persons. His electoral highness's suite at Schwetzingen, during summer, amounted to 1500 persons, who were all lodged in this little village at his expence. To a stranger walking through the streets of Schwetzingen at this time it must seem to be inhabited only by a colony of musicians, who are constantly exercising their profession: at one house, a fine player on the violin is heard; at another, a German flute; here an excellent hautbois; there a bassoon, a clarinet, a violoncello, or a concert of several instruments together. Music seems to be the chief and most constant of his electoral highness's amusements; and the operas and concerts, to which all his subjects have admission, form the judgment, and establish a taste for music, throughout the electorate.

MANHEIM, in *Geography*, a town of America, in Pennsylvania, in the county of Lancaster, containing 60 houses, and 1041 inhabitants, and a Dutch church; 11 miles N. by W. of Lancaster.—Also, a town in York county, Pennsylvania, having 1876 inhabitants.

MANI, in *Biography*. See MANICHEES.

MANI, in *Geography*, a town of Africa, in Benguela, on the coast of the Atlantic; 16 miles S. S. E. of Old Benguela.

MANIA, in *Medicine*. See MENTAL Derangement.

MANIACI, in *Geography*, a town of Sicily, in the valley of Demona; 7 miles S. W. of Randazzo.

MANIANA, a country of Africa, situated S. E. of Bambarra: the inhabitants of which are said to be cannibals. N. lat. between 13° and 14° . W. long. 1° .

MANIARY, a town of Hindoostan, in Bahar; 22 miles N. E. of Maifey.

MANJAWICK, a town of Hindoostan, in the Carnatic; 30 miles S. E. of Tanjore.

MANJAWLY, a town of Hindoostan, in Oude; 40 miles S. E. of Goorapour. N. lat. $26^{\circ} 17'$. E. long. $84^{\circ} 13'$.

MANICA, a town of Africa, the capital of Chicanga, situated on the river Sofala, S. lat. $20^{\circ} 20'$. E. long. 28° .—Also, a river which rises in Chicanga, and runs into the Indian sea, S. lat. $25^{\circ} 30'$. E. long. $29^{\circ} 30'$; called also "Rio del Lagos," and "Rio del Spiritu Santo."

MANICA, properly a sleeve. See HIPPOCRATES'S *sleeve*. Hildanus calls by this name a particular sort of purse, open at both ends, which he describes in his Treatise "De Gangræna et Sphacelo," and gives a figure thereof. This he directs to be put about a limb, just before the place of amputation, before the operation is performed.

MANICARIA, in *Botany*, so named by Gærtner, from *manica*, a sleeve, in allusion to the shape of the *spatba*, which is like a pouch or bag; whence the older botanists called the plant in question *Palma faccifera*, and Sachel Date. Gærtner. v. 2. 468. t. 176. Willd. v. 4. 493. Lamarck Illustr. t. 774.—Class and order, *Monococia Polyandria*. Nat. Ord. *Palmeæ*, Linn. Juss.

Gen. Ch. *Cal.* Common Sheath pouch-like, pointed at the base, interwoven with innumerable fibres, not bursting, widely extensible, permanent. Stalk bearing male and female flowers, enclosed within the sheath, wand-like, with numerous, simple, straight, compressed, crowded, notched, toothed, downy, rusty branches.—*Male flowers* very numerous, (above two thousand,) covering the branches of the stalk. *Cal.* Perianth of one leaf, short, angular, torn, membranous. *Cor.* obovate, triangular, of three equal coriaceous petals. *Stam.* Filaments twenty-four, capillary, distinct; anthers oblong, furrowed.—*Female flowers* few,

scarcely more than twenty, sessile on the lower part of the branches of the stalk. *Cal.* Perianth inferior, of one leaf, membranous, thin, obliquely striated, crenate and jagged. *Cor.* ovate, pointed, triangular, of three coriaceous petals, four times as large as those of the male. *Pist.* Germen superior, turbinate, triangular, of three cells; style one, short, thick, conical; stigma simple. *Peric.* Drupa globose, acutely tuberculated, dry, of three cells. *Seed.* Nuts solitary, very hard, roundish, smooth.

Eff. Ch. Common Sheath pouch-like, fibrous, not bursting.—Male, Calyx of one leaf, torn. Petals three. Stamens twenty-four.—Female, Calyx of one leaf, torn. Petals three. Style one. Drupa superior, dry, tuberculated. Nuts three.

1. *M. faccifera*. Sachel Palm. (*Palma faccifera*; Clus. Exot. 4. Bauh. Hist. v. 1. 383. Ger. em. 1554.)—Native of South America. Clusius says it was found by some Dutch sailors on a desert island in the Atlantic ocean; Gærtner, that it grows in Curaçao and Dutch Guiana. Willdenow seems wrong in considering it a native of the East Indies. Of the *tree* itself, or its foliage, nothing is known. The *spatba* is occasionally seen in the museums of the curious, and resembles a sort of netted fibrous bag, from two to four feet long, containing numerous, globular, three-celled *fruits*, the size of a large cherry, or small walnut, whose outside is strongly mucicated with sharp, prominent, unequal tubercles. Gærtner had not seen the fruit in an advanced state, or he would not have suspected that it could be the same as his *Coccos lapidea*, t. 6. f. 1.—We do not find the nuts so very hard as Clusius describes them, and therefore conclude our specimen to be but about half ripe. The coat of the drupa is of a corky substance, but densely fibrous, and is divided internally into three cells, each containing one nut, whose shell is smooth and brittle. One of the cells is occasionally abortive. Of the kernel we can determine nothing, it being but half formed.

MANICHEES, or MANICHEANS, MANICHÆI, in *Ecclesiastical History*, a sect of ancient heretics, who asserted two principles; so called from their author *Manes*, *Mani*, or *Manicheus*, a Persian by nation, and educated among the Magi, being himself one of that number before he embraced Christianity. See MAGI.

This heresy had its first rise about the year 277, and spread itself principally in Arabia, Egypt, and Africa. Dr. Lardner, after having examined many authorities, with regard to the rise of Manicheism, both in Persia and in the Roman empire, concludes with expressing his doubt whether it was known in the Roman empire before the very end of the third century, or the beginning of the fourth. St. Epiphanius, who treats of it at large, observes, that the true name of this heresiarch was Cubricus; and that he changed it for *Manes*; which, in the Persian or Babylonish language, signifies *vessel*. A rich widow, whose servant he had been, dying without issue, left him store of wealth; after which he assumed the title of the apostle or envoy of Jesus Christ.

We shall here subjoin some additional circumstances relating to this heresiarch. Mani, always so called by the Persians and Arabians, and usually denominated Manes, or Manichee, by the Greeks and Romans, was a Persian, or at least lived in the territories of the king of Persia. This is allowed by all those authors who speak of him. Cave and Tollius derive his name from the Greek noun "mania," signifying madness, intimating that his name was the same as "Manes," *i. e.* mad or furious; whereas the name is certainly Persian or Chaldaic. Cyril of Jerusalem says, that he changed his name from Cubricus to Manes, thinking by so doing to gain honour among the Persians, but

MANICHEES.

but divine providence so ordered it, that he thereby affixed to himself among the Greeks the character of madness. Beaufobre observes, that whatever was the meaning of the name, it certainly was very honourable; and if it signified any thing, it denoted some advantageous quality; for divers kings of Edeffa were named Manes, or Maanes; and Allemann says, that it was a common name of the princes of Syria and Arabia. The Greek writers continually represent Mani as a slave, purchased by a widow, and afterwards set at liberty. This widow, it is said, adopted him for her son, gave him a good education, and at length made him her heir. It has been doubted, however, whether Mani was ever a slave, as no notice is taken of this circumstance by the eastern writers: and even the Greek authors speak of him as rich, learned, educated among philosophers, and at the court of Persia in his early age. Manes, among the Greeks, was a common name for slaves; and hence it has been conjectured originated the common opinion of the Greek writers concerning Mani's servitude. The eastern authors, cited by Hyde and Herbelot, say that Mani was by profession a painter and engraver; that he had so fine a hand as to draw lines and make circles without rule or compass, and that he made a terrestrial globe with all its circles and divisions. It is also said that he was skilled in astronomy, and that he wrote a book of astrology. It is probable, according to Beaufobre, that Mani believed our earth to have two hemispheres, an upper and a lower, both inhabited; and, consequently, that there are antipodes. He is represented as a learned man and a philosopher, and it is said that he wrote a system of philosophy, and invented a musical instrument, called by the Arabians "Oud." That he was learned appears from various circumstances already recited.

Mani was not contented with the quality of apostle of Jesus Christ, but he also assumed that of the Paraclete, whom Christ had promised to send: which Augustin explains, by saying, that Mani endeavoured to persuade men, that the Holy Ghost did personally dwell in him with full authority. He left several disciples, and, among others, Addas, Thomas, and Hermas. These he sent, in his lifetime, into several provinces to preach his doctrine. Mani, having undertaken to cure the king of Persia's son, and not succeeding, was put in prison upon the young prince's death, whence he made his escape; but he was apprehended soon after, and slayed alive. Beaufobre gives no credit to the story of his attempt to cure the king of Persia's son.

The oriental writers, cited by D'Herbelot and Hyde, tell us, that Mani, having gained some esteem, began to gather together a number of people in the character of disciples, who opposed the worship and ceremonies of the religion of Zoroaster, professed at that time by the Persians. Sapor, on this account and the subsequent disturbances, would have had him punished, but Mani, perceiving his danger, fled into Turkestan, where he had full opportunity to propagate his opinions, and where he was regarded as a wonderful man, and even a god. Here it is said he lodged for a year in a cave, where he framed an imposture that multiplied the number of his followers, who all went from Turkestan into Persia upon the death of Sapor. Mani was protected in a singular manner by Hormizdas, who succeeded Sapor in the Persian throne, but he was unable to defend him, at length, against the united hatred of the Christians, the Magi, the Jews, and the Pagans: he was shut up in a strong castle, to serve him as a refuge against those who persecuted him on account of his doctrine. These writers add, that, after the death of Hormizdas, Varanes I. his successor, first protected Mani, but afterwards gave him up

to the fury of the Magi, whose resentment against him was due to his having adopted the Sadducean principles, as some say; while others attribute it to his having mingled the tenets of the Magi with the doctrines of Christianity. Varanes having at first succoured him, afterwards brought him out of his castle under a pretence of disputing with the doctors of the Zoroastrian sect, slayed him alive, filled his skin with chaff, and had it hung up in a conspicuous place to terrify those of his sect; upon which most of his followers fled into India, and some even to China. All who remained in Persia lost their liberty, and were reduced to servitude. It is generally reported, both by the Eastern and Greek writers, that Mani was put to death by a king of Persia; but they seem to have no knowledge of the death of the king of Persia's son; and it is certain that the Manicheans celebrated the day of their master's death, which is generally supposed to have happened in the year 278.

It has been a subject of much controversy, whether Mani was an impostor who pretended to prophecy and inspiration. The learned Dr. Lardner has examined the arguments on both sides; and though he does not choose to deny that he was an impostor, he does not discern evident proofs of it. He acknowledges that he was an arrogant philosopher, and a great schemist; but whether he was an impostor he cannot certainly say. He was much too fond of philosophical notions, which he endeavoured to bring into religion, for which he is to be blamed: nevertheless, he observes, that every bold dogmatist is not an impostor. Lardner allows that Mani and his followers were Christians, and held many opinions in common with other Christians.

The doctrine of Mani, says Mosheim, was a motley mixture of the tenets of Christianity with the ancient philosophy of the Persians, in which he had been instructed during his youth. He combined these two systems, and applied and accommodated to Jesus Christ the characters and actions which the Persians attributed to the god Mithras.

He established two principles, *viz.* a good and an evil one: the first a most pure and subtle matter, which he called *light*, did nothing but good; and the second, a gross and corrupt substance, which he called *darkness*, nothing but evil. This philosophy is very ancient; and Plutarch treats of it at large in his Isis and Osiris.

Our souls, according to Mani, were made by the good principle, and our bodies by the evil one; those two principles being, according to him, co-eternal, and independent of each other. In this notion, according to St. Augustin, his followers triumphed to a great degree, supposing that it afforded the best account of the origin of evil. Each of these principles is subject to the dominion of a superintending being, whose existence is from all eternity. The being who presides over the light is called God; he that rules the land of darkness bears the title of hyle, or demon. The ruler of the light is supremely happy, and, in consequence thereof, benevolent and good: the prince of darkness is unhappy in himself, and desirous of rendering others partakers of his misery, and is evil and malignant. These two beings have produced an immense multitude of creatures, resembling themselves, and distributed them through their respective provinces. After a contest between the ruler of light and the prince of darkness, in which the latter was defeated, this prince of darkness produced the first parents of the human race. The beings, engendered from this original stock, consist of a body formed out of the corrupt matter of the kingdom of darkness, and of two souls, one of which is sensitive and lustful, and owes its existence to the evil principle;

MANICHEES.

principle; the other rational and immortal, a particle of that divine light, which had been carried away in the contest by the army of darkness, and immersed into the mass of malignant matter. The earth was created by God, out of this corrupt mass of matter, in order to be a dwelling for the human race, that their captive souls might, by degrees, be delivered from their corporeal prisons, and their celestial elements extracted from the gross substance in which they were involved. With this view God produced two beings from his own substance, *viz.* Christ, and the Holy Ghost: for the Manicheans held a consubstantial Trinity. Christ, or the glorious intelligence, called by the Persians Mithras, subsisting in and by himself, and residing in the sun, appeared in due time among the Jews, clothed with the shadowy form of a human body, to disengage the rational soul from the corrupt body, and to conquer the violence of malignant matter, and he demonstrated his divine mission by stupendous miracles. The Jews, incited by the prince of darkness, put him to an ignominious death, which he suffered not in reality, but only in appearance, and according to the opinion of men. When the purposes of Christ were accomplished, he returned to his throne in the sun, appointing apostles to propagate his religion, and leaving his followers the promise of the Paraclete or Comforter, who is Mani, the Persian. Those souls who believe Jesus Christ to be the son of God, renounce the worship of the god of the Jews, who is the prince of darkness, and obey the laws delivered by Christ, and illustrated by Mani, the comforter, are gradually purified from the contagion of matter; and their purification being completed, after having passed through two states of trial, by water and fire, first in the moon and then in the sun, their bodies return to their original mass; for the Manicheans derided the resurrection of bodies; and their souls ascend to the regions of light. But the souls of those who have neglected the salutary work of purification, pass, after death, into the bodies of other animals, or natures, where they remain till they have accomplished their probation. Some, however, more perverse and obstinate, are consigned to a severer course of trial, being delivered over, for a time, to the power of malignant aerial spirits, who torment them in various ways. After this, a fire shall break forth and consume the frame of the world: and the prince and powers of darkness shall return to their primitive seats of anguish and misery, in which they shall dwell for ever. These mansions shall be surrounded by an invincible guard, to prevent their ever renewing a war in the regions of light.

Mani borrowed many things from the ancient Gnostics; on which account, many authors consider the Manicheans as a branch of the Gnostics.

In truth, the Manichean doctrine was a system of philosophy rather than of religion. They made use of amulets, in imitation of the Basilidians; and are said to have made profession of astronomy and astrology. They denied that Jesus Christ, who was only God, assumed a true human body, and maintained it was only imaginary: and, therefore, they denied his incarnation, death, &c. They pretended that the law of Moses did not come from God, or the good principle, but from the evil one; and that for this reason it was abrogated. They rejected almost all the sacred books, in which Christians look for the sublime truths of their holy religion. They affirmed, that the Old Testament was not the work of God, but of the prince of darkness, who was substituted by the Jews in the place of the true God. They abstained entirely from eating the flesh of any animal; following herein the doctrine of the ancient Pythagoreans: they also condemned marriage. The rest of their errors may be seen in St. Epiphanius and

St. Augustin; which last, having been of their sect, may be presumed to have been thoroughly acquainted with them.

Though the Manichees professed to receive the books of the New Testament, yet, in effect, they only took so much of them as suited with their own opinions. They first formed to themselves a certain idea or scheme of Christianity, and to this adjusted the writings of the apostles; pretending that whatever was inconsistent with this, had been foisted into the New Testament by later writers, who were half Jews. On the other hand, they made fables and apocryphal books pass for apostolical writings; and even are suspected to have forged several others, the better to maintain their errors. St. Epiphanius gives a catalogue of several pieces published by Mani, and adds extracts out of some of them. These are the Mysteries, Chapters, Gospel, and Treasury.

The rule of life and manners which Mani prescribed to his followers, was most extravagantly rigorous and severe. However, he divided his disciples into two classes; one of which comprehended the perfect Christians, under the name of the *elect*; and the other, the imperfect and feeble, under the title of *auditors* or *hearers*. The *elect* were obliged to a rigorous and entire abstinence from flesh, eggs, milk, fish, wine, all intoxicating drink, wedlock, and all amorous gratifications; and to live in a state of the severest penury, nourishing their emaciated bodies with bread, herbs, pulse, and melons, and depriving themselves of all the comforts that arise from the moderate indulgence of natural passions, and also from a variety of innocent and agreeable pursuits. The *auditors* were allowed to possess houses, lands, and wealth, to feed on flesh, to enter into the bonds of conjugal tenderness; but this liberty was granted them with many limitations, and under the strictest conditions of moderation and temperance. The general assembly of the Manicheans was headed by a president, who represented Jesus Christ. There was joined to him twelve rulers or masters, who were designed to represent the twelve apostles, and these were followed by seventy-two bishops, the images of the seventy-two disciples of our Lord. These bishops had presbyters or deacons under them, and all the members of these religious orders were chosen out of the class of the *elect*. Their worship was simple and plain; and consisted of prayers, reading the scriptures, and hearing public discourses, at which both the auditors and *elect* were allowed to be present. They also observed the Christian appointments of baptism of infants and the eucharist, communicating frequently in both kinds. They kept the Lord's day, observing it as a fast; and they likewise kept Easter and Pentecost.

Towards the fourth century, the Manicheans concealed themselves under various names, which they successively adopted, and changed in proportion as they were discovered by them. Thus they assumed the names of Encratites, Apotactics, Saccophori, Hydroparastates, Solitaries, and several others, under which they lay concealed for a certain time, but could not, however, long escape the vigilance of their enemies. About the close of the sixth century, this sect gained a very considerable influence, particularly among the Persians.

Towards the middle of the twelfth century the sect of Manichees took a new face, on occasion of one Constantine, an American, and an adherer to it; who took upon him to suppress the reading of all other books besides the Evangelists, and the Epistles of St. Paul, which he explained in such a manner as to make them contain a new system of Manicheism. He entirely discarded all the writings of his predecessors;

predecessors; rejecting the chimæras of the Valentinians, and their thirty Æons; the fable of Manes, with regard to the origin of rain, and other dreams; but still retained the impurities of Basilides. In this manner he reformed Manicheism, inasmuch that his followers made no scruple of anathematizing Scythian, Buddas, called also Addas and Terebinth, the contemporaries and disciples, as some say, and according to others, the predecessors and masters of Manes, and even Manes himself, Constantine being now their great apostle. After he had seduced an infinite number of people, he was at last stoned by order of the emperor.

This sect prevailed in Bosnia and the adjacent provinces, about the close of the fifteenth century; propagated their doctrines with confidence, and held their religious assemblies with impunity. See on the subject of this article, Mosheim's *Eccl. Hist.* vol. i. p. 295, &c. 8vo. edit.; Lardner's *Works*, vol. iii.; and Bayle, art. *Manichees*.

MANICHORD, or MANICHORDION, a musical keyed-instrument, in the form of a small pianoforte. See *CLAVICHORD*.

MANICKDURG, in *Geography*, a town of Hindoostan, in Berar; 5 miles S.E. of Chanda. N. lat. $19^{\circ} 59'$. E. long. $79^{\circ} 59'$.

MANICKPATAM, a town of Hindoostan, in the province of Cattaik; 50 miles S. of Cattaik.

MANICKPOUR, a circar of Oude, bounded N.E. by Oude proper, S.E. by Jionpour, S. by Allahabad, S.W. by Currah and Corah, and N.W. by Lucknow; about 60 miles long, and 40 broad.—Also, the capital of the above circar; 30 miles N.W. of Allahabad. N. lat. $25^{\circ} 50'$. E. long. $81^{\circ} 40'$.

MANICKRAJE, a town of Bengal; 42 miles S.S.E. of Dacca.

MANICOU, in *Zoology*. See *OPOSSUM*.

MANICOUAGAN, or BLACK-RIVER, in *Geography*, a river of Canada, which runs into the river St. Lawrence, near Manicouagan point, which is a cape on the north coast of the river. N. lat. $49^{\circ} 12'$. W. long. $67^{\circ} 50'$.

MANICOUAGAN, a lake of Canada; 300 miles N.E. from Quebec. N. lat. $56^{\circ} 20'$. W. long. $66^{\circ} 45'$.

MANICUM STRYCHNUM, in *Botany*, a term used by the old Greek writers to express a kind of nightshade, which, when taken internally, caused madness. Pliny, describing this species, says that it has leaves like the ocymum or basil; and Theophrastus and Dioscorides say it had leaves like the eruca or rocket. Where Pliny had his information is not easy to guess, for he commonly copies from these authors: they are, however, much more to be depended on; and as the leaves of the ocymum or basil are not at all like those of the rocket, Pliny is certainly wrong in his account; and the most probable reason for his error is that he mistook the Greek name of the plant, to which these authors compared the leaves of the manicum strychnum, and translated *euzomon*, which is the name of the rocket, into ocymum, basil; a name somewhat like the Greek one in sound, but wholly different in signification; the two plants basil and rocket not only having leaves very unlike one another, but being also of different genera. A yet greater error of Pliny, in regard to this plant, is his placing it among the esculent garden herbs, and saying that it was in use as a food, immediately after he had told us of its causing madness in those who eat it. This is an evident confusion of the maniac folanum with the pomum amoris or love apple, the fruit of which is eaten in soups at this time.

MANJEAH, in *Geography*, a town of Hindoostan, in

Bahar, on the Soane; 18 miles S. of Rotasgur. N. lat. $24^{\circ} 20'$. E. long. $83^{\circ} 57'$.

MANIEN, a small island in the Pacific ocean, near the coast of Chili. S. lat. 45° .

MANIERA, *Ital.*, *Manner*, a musical term to express a good or bad style of singing. In speaking of an individual performer, when it is said, "à una bella maniera," it implies that such performer, male or female, sings in good taste, in an elegant manner.

MANIFEST, in *Commerce*, a paper containing the particulars of a ship and cargo; which paper must be signed by the master of the vessel, before any of the goods can be landed.

MANIFESTO, an apology, or public declaration in writing, made by a prince, shewing his intentions in any enterprise, the motives that induced him to it, and the reasons on which his right and pretensions are founded.

MANIFOLD, CAPE, in *Geography*, a point of land on the coast of New Holland, or New South Wales, so called by Cook in 1770, from the number of high hills which appeared over it; lying in S. lat. $22^{\circ} 43'$, and distant about 17 leagues from cape Capricorn, in W. long. $208^{\circ} 58'$. Between these two capes lies a large bay, called "Keppel bay;" which see.

MANJHA, a town of Hindoostan, in Bundelcund; 60 miles S. of Chatterpour.

MANIHOT, in *Botany*, an Indian name for the root of which Cassava bread is made. (See *JATROPIA Manihot*.) The *Hibiscus Manihot* seems to have been so named from the resemblance of its leaves to that plant, not from any similar use or quality.

MANILIA, in *Geography*, a town of South America, in the province of Tucuman; 30 miles E.S.E. of Rioja.

MANILIUS, MARCUS, in *Biography*, a Latin poet, known only by his work, from which it should seem that he wrote in the reign of Augustus, after the defeat of Varus, and that he was, if not a native of Rome, at least a Roman subject. This poem is entitled "Astronomicum," treating, in five books, upon the fixed stars: a sixth appears to have related to the planets, but this is entirely lost. It unites the ancient system of astronomy with the philosophy of the Stoics: there are passages in it which would not disgrace any poet of the Augustan age. The work has been elucidated by some very considerable critics. Joseph Scaliger published an edition of it at Paris in 1579, and one at Leyden in 1600. The edition of our countryman Bentley, in 1739, is in high esteem. Those of Stoebcr, cum notis variorum, and of Pingrè, with a French translation, are much valued. Creech gave a translation of Manilius in English verse. The poem was discovered by the learned Poggius, in the sixteenth century.

MANILLA, in *Geography*, the capital city of Luçon, and also of the Spanish settlements in the Philippine islands. In compass it is about two miles; its length being about two-thirds of a mile; of an irregular form, narrow at both ends, and wide in the middle. It is well built; its streets are broad; its houses, though constructed of timber above the first floor, are handsome, and rendered beautiful by their galleries; and its churches are magnificent. It is a fortified city, and situated on the south-west coast, in a most advantageous position, on the banks of a considerable river, which washes its walls, and whose divided branches completely traverse the whole island. A third part of this city is occupied by convents; and the number of its Christian inhabitants is computed at 12,000. The suburbs extend to a considerable distance beyond the walls. Within a musket-shot of the gate of Parian is the habitation of Chinese merchants, called

called Sangleys, whose shops in several streets are furnished for sale with silk, porcelain, and other commodities. The number of persons, who availing themselves of the indolence of the Spaniards and Indians, profitably employ themselves in this way, is very considerable. These Sangleys are under the government of an alcaide, to whom, as well as to other officers, they allow handsome salaries. Beyond the bridge adjoining to Parian are fifteen suburbs or hamlets, inhabited by Japanese, Tagalis, and people of other nations, under the government of an alcaide. Their houses, constructed of wood, are situated near the river, and erected on pillars: the roofs are covered with palm-tree leaves, and the sides formed of canes; and they are ascended by ladders, as the ground is moist, or sometimes overflowed with water. The castle stands at the west end of the city, having the sea on one side, and the river on the other.

We shall here subjoin some additional particulars relating to Manilla and its suburbs, extracted from the first volume of the Travels of Pages, who resided some months in the island of Luçon or Luconia. The river, which flows under the city walls, is the harbour for merchant ships, and separates Manilla from the town of St. Croix. This latter town is in part equally well built with the capital, is populous in Indians and Spaniards, and is surrounded by three villages of the natives, which may be regarded as suburbs. At a short distance, on the opposite bank of the river, but on the same side with Manilla, are several considerable towns also belonging to the natives. Few merchants, and still fewer mechanics, reside within the walls of Manilla. The great seat of their manufactures, as well as the emporium of all kinds of merchandize, is the town named "Parian," on the other side of the river, which is pretty regularly built, and inhabited chiefly by Chinese. From a small colony, the population of these people has increased so as now to amount to more than 20,000, who, after engrossing the whole of the manufactures, and the principal part of the trade of Manilla, began to turn their attention to agriculture. Possessed of a considerable degree of art and address, they are sober, industrious, affable, and lively.

Among the inhabitants of Manilla are Armenian merchants, Malays, natives of the Malabar coast, and of the kingdom of Siam, and also a few Japanese.

Articles of beautiful workmanship in gold, and a species of metal named tombac, which is esteemed one-third more precious, are manufactured by the artists of Manilla; and the gold chains, made by their women, vie in beauty with the most elegant that are wrought in any part of the world.

In the year 1645, a great part of this city was destroyed by an earthquake, and 3000 persons perished in the ruins. The country surrounding this city is extremely fertile, and capable of any kind of cultivation; but the inhabitants have profited neither by the situation of the city, nor the fertility of its environs. The entrance of the river is obstructed by a bar, which is dangerous, with a rough sea; but no effectual labour has been undertaken for removing it. The soil is left uncultivated; and the law, by prohibiting exportation, discourages every attempt for increasing its produce. The consequence of this neglect has been occasional famine, when rains, or drought, or hurricanes, render the fecundity of the earth useless. The inhabitants, thus indolent in improving their natural means of wealth, direct their views and hopes towards the galleon, which sails every year for Acapulco. Formerly, a celebrated commerce was carried on between Manilla and this last-mentioned city, nearly in the same parallel on the west of Mexico, through a space of about 140°, or more than one-third of the circumference of

the globe. The Manilla ships, called *galleons* (which see), were then of large size; but at a later period, smaller vessels have been employed in this trade. The return of the galleon, or other vessels, was valued every year at Manilla at three millions of piastres, which were soon expended in merchandize, generally purchased of an English vessel under American colours. But this kind of traffic, as Sonnerat states it, is a real loss, to the inhabitants. On the one hand, they buy their merchandize at an exorbitant price; and on the other, they strip themselves of all the silver which enters their island. This writer adds, "the force of habit, the convenience of trafficking with gold instead of merchandize, which is necessarily accompanied with some trouble, makes them prefer trading in money with the English vessels to the commerce with ships from the isle of France, which would take in exchange the productions of their country, cordage, pitch, tar, cloth, sugar, oil, reeds, canes, indigo, cocoa, &c. which would be a commerce equally advantageous to both nations."

The bay of Manilla, says M. de la Perouse, is open to ships of every size, but can be defended only by men of war: any expedition, therefore, against this colony, presupposes a decided superiority of naval force. The fortifications of the place, though regular and perfectly well kept up, could only retard for a few days the surrender of a city, which cannot expect succours either from Europe, or from any other quarter. The garrison is composed of only one regiment of mulattoes. The corps of artillery, consisting of 200 men, as well as the 150 dragoons, are also Americans; and yet Perouse says, that he should not fear with 1500 men successfully to attack 3000 of them. "Upon the whole," he says, "the conquest of Manilla appears to me so easy, and so certain, with a superiority of naval force, and 5000 troops, I might answer for its success."

The city of Manilla was taken by the English in 1762; and the ransom of a million sterling remained unpaid. The Chinese, as we have already stated, were numerous in this city, till the beginning of the seventeenth century, when the Spaniards committed a dreadful massacre of these industrious people. In 1769, it is said that they were again expelled from all these isles by the bigotry of the governor; since which time there has been a great decline in industry and produce. N. lat. 14° 36' 8". E. long. 120° 51' 15". See LUÇON and PHILIPPINES.

MANILLA, a town of Hindoostan, in Mysore; 14 miles W. of Tadameri.

MANILLE, or MENILLE, in *Commerce*, one of the principal commodities carried by the Europeans to the coasts of Africa, to traffic with the Negroes in exchange for slaves. It is a large brass ring in form of a bracelet, either flat or round, plain or engraved; with which the natives used to deck themselves, putting them on the small of the leg, and the thick of the arm above the elbow.

The better sort among the Negroes wear silver and gold manilles; but these were of their own manufacture; most of the money they receive for their own merchandize being melted into manilles.

MANILLON, in *Geography*, a township of America, in Fayette county, Pennsylvania, containing 1207 inhabitants.

MANILVA, a town of Spain, not far from the route from Malaga to Gibraltar, situated across the mountains from Guayaro, and belonging to the house of Arcos. It is surrounded with vineyards, which produce an exquisite rich wine, known by the name of Manilva wine.

MANIMBODU, a town of Hindoostan, in the Carnatic; 15 miles S.W. of Pondicherry.

MANIMUNGALUM, a town of Hindoostan, in the Carnatic; 16 miles S. W. of Madras.

MANINGEABO. See **MENANGEABO**.

MANINGTREE, or **MANNINGTREE**, a small irregular town in the hundred of Tendring, and county of Essex, England, is situated on the southern banks of the river Stour, nine miles distant from Colchester, and 61 from London: though only a chapelry to the parish of Mitley, it has the privilege of a market. Whence it derived its present name is uncertain: its ancient appellation was Sciddinchou, by which it is mentioned in Domesday book, as being then held by Adeliza, countess of Hereford and Gloucester, who bestowed the manor on the nunnery of the order of St. Augustine, at Canon-Lugh, in Devonshire. After the dissolution, Manningtree (called in the grant Many-tree, alias Scidinghoo) was given by Henry VIII. to Sir John Rainworth. In the certificate of chantry lands it is called "a great towne, and also a haven towne, having in yt to the number of 700 howeling people." In the year 1801, the population, as ascertained under the act of parliament, was 1016, occupying 129 houses. 953 of the inhabitants were returned as being employed in various trades and manufactures. The market is kept on Thursdays; and an annual fair on the Thursday in Whitfun week. The river Stour was made navigable from this town to Sudbury in Suffolk, by an act passed in the fifth year of queen Anne. The principal imports are deals, corn, coals, iron, and fish. Beauties of England and Wales, vol. iv.

MANIPA, one of the smaller Molucca islands, about 2500 toises in extent from N. to S. Although this island is very mountainous, it is populous, and contains about 1600 inhabitants; and many canoes ply along its shore: five or six leagues W. from Ceram. S. lat. $3^{\circ} 21'$. E. long. $127^{\circ} 54'$. —Also, a river on the W. coast of Celebes, which runs into the sea, S. lat. $3^{\circ} 12'$.

MANIPULATION, a term used in the mines, to signify the manner of digging the silver, &c. out of the earth.

MANIPULUS, **MANIPULE**, among the Romans, was a little body of infantry, which, in the time of Romulus, consisted of a hundred men, and in the time of the consuls and first Cæsars, of two hundred.

The word properly signifies a handful; and, according to some authors, was first given to the handful of hay which they bore at the end of a pole, to distinguish themselves by, before the custom was introduced of bearing an eagle for their ensign; and hence also the phrase, a handful of men. But Vegetius, Modestus, and Varro, give other etymologies of the word: the last derives it from *manus*, a little body of men following the same standard. According to the former, this corps was called *manipulus*, because they fought hand in hand, or all together: "Contubernium autem manipulus vocabatur ab eo, quod conjunctis manibus pariter dimicabant."

Each manipule had two centurions, or captains, called *manipularii*, to command it; one whereof was lieutenant to the other. Each cohort was divided into three manipules, and each manipule into two centuries.

Aulus Gellius quotes an old author, one Cincius, who lived in the time of Hannibal (whose prisoner he was), and who, writing on the art of war, observes, that then each legion consisted of sixty centuries, of thirty manipules, and of ten cohorts. And again, Varro and Vegetius mention it as the least division in the army, only consisting of the tenth part of a century; and Spartan adds, that it con-

tained no more than ten men. This shews that the manipulus was not always the same thing. See **LEGION**.

MANIPULUS is also an ecclesiastical ornament, worn by the priests, deacons, and sub-deacons, in the Romish church. It consists of a little silet in form of a stole, three or four inches broad, and made of the same stuff with the chafuble; signifying and representing an handkerchief, which the priests in the primitive church wore on the arm, to wipe off the tears they were continually shedding for the sins of the people. There still remains a mark of this usage in a prayer rehearsed by those who wear it; "Merear, Domine, portare manipulum sletus & doloris."

The Greeks and Maronites wear two manipules, one on each arm.

MANIPULUS, in *Physic*, denotes a measure, or fixed quantity, of herbs, or leaves, viz. a handful; or so much as the whole hand can grasp: it is generally marked in prescription, with an *M*.

MANIQUE, in the *Materia Medica*, the name given by authors to an American root, commended greatly for curing tertian and quartan agues, and as an infallible remedy against venomous bites. Redi procured some of this famous root, and gave it many very fair trials, but could never discover any of these virtues in it.

MANIS, in *Natural History*, a genus of quadrupeds the class Mammalia, and order Bruta, of which there are, according to Gmelin, two species, but Dr. Shaw mentions three. The generic character is, that it has no teeth; the tongue is round, and extensile; the mouth is narrowed into a snout; the body is covered above with moveable bony scales.

This genus presents an appearance as extraordinary as that of the *Dasyus*, being covered on every part, except the belly, with strong and large scales, constituting a complete suit of armour, capable of defending the animals, when rolled up, from the assaults of the most ferocious enemies. This covering, together with the length of the body and tail, gives an aspect so much resembling that of a lizard, that the creatures of the genus are commonly known by the name of the scaly lizards, though they are in no other respects allied to the lizard tribe than in their covering. They are, however, admitted to form a sort of link of approximation between the proper viviparous quadrupeds and the lizards. In their nature they are harmless, and feed in the same manner as the ant-eaters, by thrusting out their very long tongue into the nests of ants and other insects, and swallowing their prey, by suddenly drawing it back. They are found chiefly in India and the India islands.

Species.

PENTADACTYLA, five-toed or short-tailed manis. The tail in this species is not so long as the body, it is very thick at the base, and from thence gradually tapering, but ending obtusely. The head is small, and the ears are likewise small and rounded. The feet are furnished with five toes each, of which those on the fore-feet are extremely strong, except the exterior one, which is much smaller than the rest. The whole animal is covered with thick, strong, and large scales, which, when full grown, are perfectly smooth, but in those which are smaller, they are striated about half way from the base. They are channelled at the base, but at the edges they are sharp, rounded, and imbricate. It inhabits Guinea, China, and India. The colour of the animal is of a pale yellow-brown, and the surface is glossy. It measures, including the tail, from six to eight feet in length. In Bengal, it has obtained the name of the "Thunderbolt Reptile," from the hardness of its scales, which are said to be capable

of striking fire like a flint. It lives in woods and marshy places, and feeds on ants, by laying its long tongue across their paths. It walks slowly, and when pursued, rolls itself up, and is then so securely armed, that even a leopard attacks it in vain. It is said to be capable of destroying the elephant, by twisting itself round the trunk, and thus compressing that tender and sensible organ with its hard scales.

TETRADACTYLA, four-toed or long-tailed manis. This animal is less than that already described; it is found in India; the scales are much channelled, each is armed with three points; the under parts are covered with hair, and the tail is three times as long as the body. The legs are very short, and scaled like the body, and on each of the feet are four claws, of which those on the fore-feet are stronger than those on the hind. The colour is a uniform deep brown, with a yellowish cast, and with a glossy or polished surface. From the tip of the nose to the extremity of the tail, its whole length is about five feet.

LATISSIMA, or broad-tailed manis, is denominated, in the sixtieth volume of the Philosophical Transactions, in which there is a figure of the animal, the "New Manis." The creature here described was killed in the house of a merchant at Tranquebar, having been discovered in the cavity of a wall. When attacked it rolled itself up in such a manner as to leave only the back and tail visible, so that it was destroyed with much difficulty. It had five toes on the fore-feet, and four on the hind; the scales were of the shape of a muscle; the belly quite smooth; the exterior scales ended in a sharp point, somewhat incurved; the tail was very broad, decreasing to a point. It is doubtful, after all, whether this animal belongs to a distinct species, or whether it be a variety of one of those already noticed. "In reality," says Dr. Shaw, "the differences do not seem sufficient to constitute a specific distinction, and are, probably, owing to the differences of age and sex. In the British Museum there are specimens of different sizes, which shew these gradations. In one, the scales, all over the animal, are so regularly and completely truncated at the extremity, as to exhibit the appearance of so many hexagons. In another they are remarkably broad and rounded; and in a third, which is a very large specimen, they are less obtuse at the tips, and somewhat irregularly terminated, as if notched, or worn through age. The proportional breadth of the tail also varies somewhat in these specimens, and seems greatest in those which are the least advanced in age."

MANISSA, in *Geography*, a river of Africa, forming the southern boundary of Inhambane, and running into the Indian sea, S. lat. $25^{\circ} 50'$.

MANISTIE, a river of Canada, which runs into lake Michigan, N. lat. $45^{\circ} 36'$. W. long. $85^{\circ} 40'$.

MANISURIS, in *Botany*, a grass most aptly so named by Linnæus, from *Manis*, the Scaly Lizard, and *ovis*, a tail, the singular appearance of its scaly spikes recalling very strongly the idea of the no less extraordinary covering of that quadruped. Linn. Mant. 164. Schreb. 719. Mart. Mill. Dict. v. 3. Linn. fil. Nov. Gram. Gen. 21. t. 1. Juss. 34. Lamarck Illustr. t. 839. Gært. t. 175. Class and order, *Polygamia Monocia*. Nat. Ord. *Gramina*.

Gen. Ch. *Perfect Flowers* imbricated, alternate, at the opposite sides of a zigzag jointed spike, one to each joint, which is hollowed out to receive the base of the flower. *Cal.* Glume of two valves, single-flowered; the *outermost valve* largest, coriaceous, rounded, rugged in the middle, either notched or entire at the top and sides; *innermost* smaller, broadly lanceolate, membranous, closely pressed to the former. *Cor.* Glume of two valves, membranous, thin

and transparent, smaller than the calyx and concealed therein; the *outer valve* embracing with its edges the *inner*, which is smaller. Nectary a membranous scale. *Stam.* Filaments three, capillary, prominent; anthers oblong, incumbent. *Pist.* Germen ovate, superior; styles two, short, thread-shaped; stigmas oblong, bearded, spreading beyond the glumes at each side. *Peric.* none, the calyx inclosing the seed. *Seed* solitary, ovate.

Male Flowers marginal, alternate, at the back of the spike, projecting at each side, one to each joint. *Cal.* Glume of two valves, single-flowered, nearly cylindrical; the *valves* equal, parallel, ovato-lanceolate, obtuse, striated, coriaceous, bordered with a membrane. *Cor.* Glume of two valves, membranous, thin, nearly as large as the calyx; the *outer valve* ovate, obtuse, convoluted; *inner* lanceolate, plaited, scarcely longer than the outer. Nectary a membranous scale. *Stam.* Filaments three, very short, sometimes wanting; anthers as in the perfect flowers.

Ess. Ch. Perfect Flowers. Calyx a glume of two unequal, opposite valves, single-flowered; the outer valve rounded and rugged. Corolla smaller than the calyx. Stamens three. Styles two.

Male Flowers. Calyx of two equal, parallel, oblong valves.

Obs. This genus is one of the few that may properly be allowed to remain in the class *Polygamia*, as having a very different structure in the two different kinds of flowers. Such is the case with the British genus *Atriplex*, but with few others admitted into this class by Linnæus. These however, in our opinion, excuse, if not justify, the preservation of it in the Linnæan system.

1. *M. myurus*. Mouse-tail Scaly-grass. Linn. Mant. 300. Linn. fil. Nov. Gram. Gen. t. 1. f. 1—3. Roxb. Corom. v. 2. 10. t. 117.—Outer glume of the perfect flowers elliptical, depressed, notched at the top and sides. Sheaths of the leaves smooth.—Found by Koenig in dry elevated barren ground on the coast of Coromandel, not unfrequent. Dr. Roxburgh gathered it in the same country, and informs us that it is called by the Telingas *Nalla Panocoo*. The root appears to be perennial, consisting of long, tough, downy fibres. Stems several, branched, jointed, leafy, smooth, compressed, solid, from 9 to 18 inches tall; decumbent and throwing out roots at their lower part. Leaves alternate, channelled, short, narrow, acute, smooth, with long inflated sheaths. Spikes about two inches long, linear, solitary at the ends of the principal, as well as the short lateral branches, composed of numerous, closely imbricated, flowers. The outer glume of such as are furnished with both stamens and pistil is shaped like a fiddle, its disk marked with two transverse elevations, and somewhat hairy, its membranous margin purplish. Dr. Roxburgh found two male florets in the oblong-leaved calyx, and his description of the structure and position of the calyx-glumes differs from that we have adopted, as well as from what we can discern in the dried specimen, in which those valves are certainly parallel, not opposite to each other, a very remarkable and distinguishing character between the male flowers and the perfect ones. The common stalk, or *rachis*, is zigzag, consisting of short, turbinate, angular, slightly downy joints, each of which bears near its base, on one side, a single perfect flower, and at its summit, on the opposite side, a male flower.

2. *M. granularis*. Granulated Scaly-grass. Linn. fil. Nov. Gram. Gen. t. 1. f. 4—7. Swartz Prodr. 25. Ind. Occ. v. 1. 186. Roxb. Corom. v. 2. 11. t. 118. (*Cenchrus granularis*; Linn. Mant. 575. *Gramen cyperoides polytachion*, spicis ad nodos ex utriculis, seu foliorum alis, echinatis,

echinatis, prodeuntibus; Sloane Jam. v. 1. 120. t. 80.)—Outer glume of the perfect flowers orbicular, convex, entire, reticulated. Sheaths of the leaves hairy.—Native of the East and West Indies. Dr. Swartz gathered it in dry calcareous situations, in the south part of Jamaica; Roxburgh in bushy places, on the coast of Comorandel. The latter observes that both this and the foregoing are coarse grasses, not eaten by cattle. The root of the present is said by Swartz to be annual. It consists of numerous, nearly smooth, fibres. Stem a foot or two in height, branched from the bottom, leafy, round, smooth, slender. Leaves broad, taper-pointed, more or less hairy, with tumid, ribbed, very hairy, and minutely tuberculated, sheaths. Spikes solitary, at the ends of small, lateral, axillary, leafy branches. Each spike is about an inch long, composed of numerous imbricated flowers, on a zigzag stalk, the united ones conspicuous on one side, the males on the other. The outer calyx-glume of the former is orbicular, pale or purplish, the size of a small pin's head, strongly reticulated with elevated ribs, and intermediate depressions. Swartz says there are two inner glumes, which are ovate, nearly equal, pointed, white and pellucid. Roxburgh's figure does not accord with this. The former writer describes the corolla as of two minute, ovate, whitish glumes, half the size of the outer valve of the calyx, and the nectary of two extremely diminutive, fleshy, whitish scales, forming a cup at the base of the germen and stamens. The male flowers are rather larger, each consisting of two parallel, equal, ovate calyx-glumes, which are striated and hispid, with a small, white, bivalve corolla, and a similar nectary to the other. S.

MANITOU, or MANITOUALIN Islands, in Geography, a cluster of islands towards the N. shore of lake Huron, stretching from the vicinity of Cabots head, north-westerly across the lake to lake George, below the falls of St. Mary. These islands are held sacred by the Indians.

MANITOU Kiamen, a post of Chinese Tartary, in the country of the Kalkas. N. lat. 43° 22'. E. long. 106° 40'.

MANITOU Oudour, a town of Chinese Tartary, in the country of the Monguls. N. lat. 42°. E. long. 112° 14'.

MANITZKAIA, a town of Russia, in the country of the Cossacks; 40 miles E.N.E. of Azof.

MANIVAL, a town on the E. coast of Madagascar. S. lat. 17° 10'. E. long. 50°.

MANKAKO, a town of the island of Celebes, in Buggefs bay, in which is a good market for gold and sago. S. lat. 1° 45'.

MANKALIA, a sea-port town of Bulgaria, on the Black sea; 68 miles E.S.E. of Silistria. N. lat. 44°. E. long. 28° 39'.

MANKANET, or ST. JOSEPH, a town of Africa, in Galam, in which is a French factory.

MANKAP, a small island in the East Indian sea, near the S. coast of Borneo. S. lat. 3° 2'. E. long. 109° 58'.

MANKETS. See NOGAYANS.

MANKOVA, a town of Russia, in the government of Irkutsk, on the Angara; 44 miles S.E. of Balaganstok.

MANKOUH, a town of Persia, in the province of Khorasan; 66 miles N. of Meshid.

MANKOW. See Ivory COAST.

MANKUTOSKA, a town of Russia, in the government of Irkutsk; 28 miles N. of Stretensk.

MANLIUS, MARCUS, surnamed *Capitolinus*, in Biography, a distinguished Roman, was brought up to arms, and is said to have already served the office of consul, when he was one of the garrison of the Capitol at its siege by the Gauls in the year 390. On the attempt of the enemy to

surprise it by night, Manlius was the first person awakened by the noise of the geese kept in the fortrefs. He ran to the ramparts, threw down two Gauls who had mounted to the top; and the alarm being caught by the centinels, the enterprize was defeated, and the Capitol saved. For this heroic act, Manlius received a house in the Capitol; with the title of Capitolinus. The high reputation which he now enjoyed, stimulated his ambition to become the first man in Rome. Camillus, the saviour of his country, was at the head of the patrician party, and Manlius, jealous of his power, threw himself into the opposite party, and began to court the Plebeians, by railing at the rich, and patronizing their insolvent and enslaved debtors, of whom there was always a great number in Rome. He liberated several of these at his own expence, and stood forth as the public advocate of the people in the division of the conquered lands. On account of some false charges which he exhibited against the nobles, he was thrown into prison; still, however, he was regarded as the hero of the party, and when he was liberated, he kept no measure in his hostility to the nobles, but proposed the abolition of consulates and dictatorships, and a perfect equality of rights. He offered himself as a leader to enforce these changes, and is said to have formed a plot to seize the Capitol, and usurp the sovereign power. The senate now passed a decree, enjoining the military tribunes "to take care that the republic should suffer no detriment," which was the form of investing them with absolute power. Manlius was charged with the crime of aiming at regal power; he appeared before his judges with mourning, unsupported by his nearest relations, who were of the opposite party. To excite the favour and compassion of the people, he produced four hundred persons whose debts he had paid; he displayed thirty suits of armour won from as many foes slain by him in single combat; a mural crown, and eight civic crowns; and he enumerated thirty-seven rewards received from his generals for acts of extraordinary valour. Lastly, he pointed to the Capitol itself, which he had saved, and which was full in view from the Campus Martius, the place of trial, and invoked its gods to his assistance. So long as this object was in their sight, the people refused to find him guilty, but when the place of assembly had been altered to a grove from which the Capitol could not be seen, sentence was obtained against him, and he was condemned to be thrown down from that very rock which he had defended from the attack of the Gauls. This execution took place in the year 384 B.C., and a decree was at the same time passed, that no patrician should from that time dwell in the Capitol. Plutarch. Livy.

MANLIUS, TITUS, surnamed *Torquatus*, a celebrated commander of the same family with the preceding, the son of Titus Manlius Imperiosus, who after he had served the office of dictator in 363, was cited before the people to answer for various acts of cruelty, and one of the charges against him was for keeping his son Titus, in the country, at work among his slaves, for no other reason than that he was of slow parts, and had an impediment in his speech. The young man being informed of this accusation, went to Rome by night, and proceeded directly to the house of the tribune Pomponius, his father's accuser, demanded a private interview; then drew a dagger and threatened him with instant death unless he took an oath to drop the prosecution against his father, with which he very readily complied. The people were so well pleased with this instance of filial piety, though in favour of a man whom they detested, that they raised the young Titus to the post of legionary tribune. Some time afterwards, when the Gauls, invading the Roman territory, had advanced within three miles of

the city, and both armies lay on opposite banks of the Anio, one of the enemy, of gigantic stature, came to the bridge and challenged the bravest man among the Romans; Manlius begged to be allowed to accept the challenge, and armed with a short sword and buckler advanced to the encounter. Victory decided in his favour, and the Gauls, considering the death of their champion as an omen of ill success, abandoned their camp in the night, and made a precipitate retreat. Manlius obtained the name of "Torquatus" from having torn a golden collar from the neck of his antagonist, and putting it on his own. In the year 355, he was nominated to the dictatorship, though he had not yet been consul, on account of his great merit. He was a second time dictator, and then succeeded to the consulship. In the year 340, he marched with Decius Mus, to suppress a dangerous war with the Latins, and it was resolved, that no soldier nor commander should quit his ranks, or even fight, without express permission, on pain of death. Soon after Manlius, the son of Torquatus, who commanded a detachment of horse, meeting with a squadron of the enemy, was challenged to single combat by its leader; he in the height of his ardour accepted the offer, and slew his antagonist. Having stripped him of his armour, he went triumphantly to his father's tent, and relating the deed, laid the spoils at his feet. The consul immediately, and in the presence of the Roman army, pronounced against him sentence of death for disobedience of orders. In the ensuing battle, Decius was slain, and the event remained in doubt, till Manlius, by a skilful movement, decided the day and gained a complete victory. On his return to Rome, he was received with honour by the seniors, but the younger part of the citizens abhorring his rigour towards his son, refused to go out to meet him. He was afterwards offered the consulship by general consent, but he declined it, telling the people, that as they could not bear his severity, so neither could he put up with their licentiousness. Livy. Univer. Hist.

MANLIUS, in *Geography*, a post-town in Onondago county, New York, incorporated in 1794, and the seat of the county courts. It is well watered by several creeks, which unite at the N.E. corner of the town; and the stream assuming the name Chittenengo, runs N. to Oneida lake, lying 10 miles N. of the centre of the town. It comprehends that part of the Onondago reservation, bounded S. by the Genesee road, and W. by Onondago creek and the Salt lake. It contains 989 inhabitants.

MANNA, a district, and also a river, on the south-west coast of the island of Sumatra. In this district a progress in the art of cultivation is discovered, superior to what appears in almost any other part of the island; that occupied by the Battas excepted. Here the traveller may see pieces of land, in size from five to fifteen acres, regularly ploughed and harrowed. Mr. Marsden accounts for this difference by observing that Manna is by much the most populous district to the southward, with the smallest extent of sea-coast. Necessity obliges them to cultivate the earth; or otherwise they would be obliged to abandon their native soil. In order to understand the rate of produce, we must first explain the terms used in describing it. "Paddee" is rice whilst it is in the husk; and paddee in Sumatra and the Malay islands is distinguished into two sorts, viz. "laddang," or upland paddee, and "sawoor," or low-land; and these are always kept separate, and will not grow reciprocally. From grounds tilled as they are, in the district of Manna, the produce is reckoned at 30 for one; from the laddangs in common it is about 60 or 80. The sawoors are generally supposed to yield an increase of 100 for one, but in some of the northern parts 120. The excess of this proportion of

produce above that of our fields in Europe, which seldom exceeds 15, and is often under 10, is ascribed to various circumstances; viz. the difference of grain, rice being extremely prolific; the more genial influence of a warmer climate; and the earth's gradually losing, by an excessive cultivation, its fecundity; but principally, as Mr. Marsden conceives, to the different style of cultivation. The Sumatrans, who do not grudge time or labour, make holes in the ground, and drop into each a few grains; or, by a process still more tedious, raise the seed in beds, and afterwards plant it out. The district of Manna, as well as other parts of Sumatra, is subject to very destructive earthquakes. By a severe calamity of this kind that occurred in 1770, a village was destroyed by the houses falling down and taking fire, and several lives were lost. The ground in one place was rent for a quarter of a mile to the width of two fathoms and depth of four or five. A bituminous matter is described to have swelled over the sides of the cavity, and the earth, for a long time after the shock, was observed to contract and dilate alternately. Many parts of the hills far inland, could be distinguished to have given way, and as a consequence of this, Manna river was so much impregnated with particles of clay that the natives could not bathe in it. At this time was formed, near to the mouth of Padang-goochie, a neighbouring river, south of the former, a large plain, seven miles long, and half a mile broad, where had before been only a narrow beach. A small but beautiful cascade descends perpendicularly from the steep cliff, which, like an immense rampart, lines the sea-shore near Manna. No country in the world is better watered than this. Springs are found wherever they are sought for. The rivers on the western coast are innumerable, but too small and rapid for the purposes of navigation. The vicinity of the mountains to that side of the island occasions this profusion of rivulets, whilst it prevents their accumulating to any size. At Manna the "Soompatan," that is, the swearing apparatus, on which an oath is administered, is a gun-barrel. When used for this purpose, it is carried to the spot in state, under an umbrella, and wrapt in silk. This parade has an advantageous effect, by influencing the mind of the party with an high idea of the importance and solemnity of an oath. In England it is to be regretted, that the familiarity of the object, and the summary method of administering oaths, are well known to diminish their influence, and to render them too often nugatory. The Sumatrans sometimes swear by the earth, laying their hands upon it, and wishing that it may never produce ought for their nourishment if they speak falsely. Marsden's Sumatra. The town of Manna is distant 300 miles S.W. from Indrapour. S. lat. 4° 25'. E. long. 102° 40'.

MANNA, a town of Africa, in Jallonkadoo, near the Senegal. N. lat. 12° 20'. W. long. 8° 50'.

MANNA, in *Pharmacy*, a medicinal drug, of great use in the modern practice, as a gentle purgative, and cleanser of the first passages.

Manna is a white sweet juice oozing from the trunk, branches, and leaves of a kind of ash-tree, being the *FRAXINUS Ornus* (which see), chiefly in Calabria, during the heats of summer.

Manna has been erroneously held to be a kind of *mel acrium*, or honey-dew, which, falling in the night, gathers on certain trees, and even on rocks, and on the earth itself; where it hardens with the sun. But what refutes this opinion is, that such dews melt in the sun; whereas manna whitens and hardens in it. Add, that such dews are only found on the tops and extremes of the leaves, whereas manna is chiefly found to lodge on the trunks of the branches: and that the honey-

juice falls only on trees open to the air; whereas manna is found on trees which are under cover; as was experienced by Dr. Cornelius, who gathered manna from branches covered on purpose with cloth; and Lobel assures us, that manna had been gathered from branches of the ash, which had been thrown the day before into a cellar. It is much more rational to rank manna amongst the number of gums, which, exuding from the juice of the tree, is condensed into those flakes in which we see it.

Manna is far from being peculiar to the ash-tree of Calabria, on which it is usually found. The *Ornus* is not the only species of Ash or *Fraxinus* which produces it. It is afforded, though in less abundance, particularly in Sicily, by the *Fraxinus rotundifolia* and *excelsior*: these three species are cultivated in Sicily, and planted on the declivity of a hill, with an eastern aspect for the purpose of procuring manna. After ten years' growth, the trees begin to yield the manna, but they do not afford it in very considerable quantity till they are much older; and as manna is no other than the matter of the sensible transpiration of trees and plants in general, it is found on many different kinds, in different quantities.

At Briançon, in France, they collect manna from all sorts of trees that grow there; and the inhabitants observe, that such summers as produce them the greatest quantities of manna, are very fatal to their trees. Their walnut-trees produce annually a considerable quantity; but if there happen a year in which they produce more than ordinary, they usually find many of them perish in the following winter.

It seems very plain from the whole, that manna is only the extravasated juice of the tree, which cannot survive to great a loss of it: and what not a little confirms this is, that the very hot summers are always those which are the most abundantly productive of manna. The ancients were sensible of this spontaneous production of manna, of several species of trees, so very different from one another, and from thence fell into the error of supposing it something wholly foreign to the tree; an error very natural to those who did not know that the nutritive juices of very many trees are nearly, if not wholly the same. It was from this opinion of its origin, that they called it aerial honey.

Dr. Cullen very properly supposes manna to be a part of the sugar so universally present in vegetables, and which exudes on the surface of a great number of them; and he thinks that the qualities of these exudations are very little, if at all different. The principal trees known to produce these mannas in different climates and seasons are, the larch, the fir, the orange, the walnut, the willow, the mulberry, oaks, the *hagi Maurorum*, or *Hedysarum alhagi* of Linnæus. Of this latter Dr. Fothergill presented a specimen to the Royal Society, which he considered as the "Tereniabin" of the Arabians. (*Phil. Transf.* vol. xliii. p. 87.) The *Cistus ladaniferus* in some parts of Spain produces a manna, which, in its recent state, has no purgative quality, and is eaten by the shepherds, so that some fermentation seems to be necessary, in order to give it a cathartic power.

The Italians gather three kinds of manna:—*Manna di corpo*, which oozes spontaneously from the branches of the tree in the month of July. *Manna forzata*, or *forzatella*, which is not gathered till August, after an incision of the tree, when the flux of the first has ceased. *Manna di fronda*, which issues of itself, in little drops, like a kind of sweat, from the nervous part of the leaves of the ash, and gathers into grains about the bigness of those of wheat, which are hardened by the sun in August. The leaves are frequently found so laden with these grains, that they seem covered with snow.

Although the manna exudes spontaneously upon the ash-

trees, yet for obtaining it more copiously, incisions are made through the bark by means of a sharp crooked instrument; and the season thought to be the most favourable for instituting this process is a little before the dog-days commence, when the weather is dry and serene. The incisions are first made in the lower part of the trunk, and repeated at the distance of an inch from the former wound, still extending the incisions upwards as far as the branches, and confining them to one side of the tree; the other side being reserved till the year following, when it undergoes the same treatment. On making these incisions, which are of a longitudinal direction, about a span in length, and nearly two inches wide, a thick whitish juice immediately begins to flow, which gradually hardens on the bark, and in the course of eight days acquires the consistence and appearance in which the manna is imported into Britain, when it is collected in baskets, and afterwards packed in large chests. Sometimes the manna flows in such abundance from the incisions, that it runs upon the ground, by which it is mixed with various impurities, unless prevented, as is usually the case, by interposing large concave leaves, stones, chips of wood, &c. The business of collecting manna usually terminates at the end of September, when the rainy season sets in. Dr. Cirillo's account of the manner of collecting manna in the kingdom of Naples was communicated to the Royal Society, and was published in *Phil. Transf.* vol. ix. This ingenious writer begins with correcting a mistake, founded on an erroneous opinion of the ancients, which states the best and purest manna to be that which is obtained from the leaves of the tree. He never saw such a kind, and all those who are employed in the gathering of the manna, know of none that comes from the leaves. The manna is generally of two kinds, not differing in their intrinsic quality, but in the manner by which they are procured. In order to have the manna, says our author, those who have the management of the woods of the Orni in the months of July and August, when the weather is very dry and warm, make an oblong incision, and take off from the bark of the tree about three inches in length and two in breadth; they leave the wound open, and by degrees the manna runs out, and is almost suddenly thickened to the proper consistence, and is found adhering to the bark of the tree. This manna, which is collected in baskets, and goes under the name of "manna grossa," is put in a dry place, because moist and wet places will soon dissolve it again. This first kind is often in large irregular pieces of a brownish colour, and is frequently full of dust and other impurities: But when the people want to have a very fine manna, they apply to the incision of the bark thin straw, or small bits of shrubs, so that the manna, in coming out, runs upon those bodies, and is collected in a sort of regular tubes; which gives it the name of "manna in cannoli," that is, manna in tubes: the second kind is more esteemed, and always preferred to the other, because it is free and clear. There is indeed a third kind of manna, which is not commonly met with, and which our author says he has seen since he left Calabria: it is very white, like sugar; but as it is rather for curiosity than for use, he says no more of it. The two sorts of manna already mentioned undergo no kind of preparation whatsoever, before they are exported; sometimes they are finer, particularly the "manna grossa," and sometimes very dirty and full of impurities; but the Neapolitans have no interest in adulterating the manna, because they have always a great deal more than what they generally export; and if manna is kept in the magazines, it receives often very great hurt by the southern winds, so common in our part of the world. The changes of the weather produces a sudden alteration in the time that the manna is to be gathered; and for

for this reason, when the summer is rainy, the manna is always very scarce and very bad.

Manna is generally distinguished into different kinds, *viz.* the manna in tears, the canulated and flaky manna, and the common brown or fat manna; differences which depend upon their respective purity, and the manner in which they are procured from the tree, and not upon the nature of the drug itself. When the juice transudes very slowly, the manna is more dry, transparent, and pure, and consequently of higher estimation; but when it flows more copiously, it concretes into a coarse brown unctuous mass; and hence we perceive that by applying straw, &c. to receive the flowing juice, the manna becomes much improved. Houel, who tasted the manna when flowing from the tree, found it much more bitter than in its concrete state; and this bitterness he ascribes to the aqueous part, which is then abundant: whence it appears that the manna is meliorated by all the circumstances which promote evaporation. Manna is a substance in many things very nearly related to sugar and to honey; it is inflammable in the same manner, and it melts in water as easily as sugar, and liquifies even in a moist air, and by the assistance of heat, in rectified spirit also; the impurities only being left by both menstrua. On inspissating the watery solution, the manna is recovered of a much darker colour than at first. From the saturated spirituous solution great part of it separates as the liquor cools, concreting into a flaky mass, of a snowy whiteness, and a very grateful sweetness. When exposed on hot coals, it swells, takes fire, and leaves a light bulky coal. When boiled with lime, clarified with white of egg, and concentrated by evaporation, it affords crystals of sugar. By distillation manna affords water, acid, oil, and ammonia; and its coal affords alkali.

M. Lemery, in his analysis, drew from manna a vinous liquor, of the same kind with that obtained from honey. Mead may also be made of manna, in the same way that it is made from honey; but it is neither so strong, nor so agreeable to the taste as that of honey. From as much mead as was made from two pounds of manna, M. Lemery drew off by distillation eight ounces of a sort of brandy, and on rectifying this, procured an ounce and a half of a pure burning spirit, like in all respects to rectified spirit of wine. This spirit of manna is accounted by some a sudorific, and is given from half a dram to a dram and a half. M. Lemery having left the remaining liquor, after the distillation of the spirituous part of the manna mead, in a warm place for two years, found that it deposited to the bottoms of the bottles seven drams of an essential salt of manna, which was white, hard, brittle, and formed into fine needles, and was of an acid taste, with an admixture of sweet. This salt is purgative, and its dose is a dram. All the remaining acid liquor being distilled, there remained at the bottom of the retort a quantity of matter of the consistence of honey, which weighed twenty ounces; so that out of two pounds of manna, there had been twelve ounces consumed, to make the spirit, and to give the acidity to the remaining liquor. This honey-like residuum, being finally distilled with a strong fire, there arose a reddish liquor of an acrid taste, and with a strong empyreumatic smell, and with this a few drops of blackish oil; after this operation, the remainder in the retort was four ounces of a very light black coal. The coal, it is to be observed, is here only one-eighth of the weight of the manna, which is somewhat singular, since in the purest honey, treated in the same manner, it always weighs one-fourth of the original whole quantity. It is plain from hence, that manna is a much purer substance than honey: it is also remarkable, that in farther treatment of this coal, there is a small quantity of iron always discovered in it.

VOL. XXII.

Manna, honey, and all the other sweet substances, we see, also lose all their sweetness as soon as ever their acid is separated from their oil. Hist. Acad. Par. 1708, p. 56.

The best sort of manna is that in oblong pieces or flakes, moderately dry, friable, very light, of a whitish or pale yellow colour, and, in some degree, transparent: the inferior kinds are moist, unctuous, and brown. Manna of both sorts is sometimes counterfeited by compositions of sugar, honey, and purgative materials, which may be distinguished in their solid form by their weight, compactness, and transparency; and in the dry and moist state, by their taste, and by their habitude to menstrua. Manna, in doses of an ounce and upwards, proves a gentle laxative; it operates in general with great mildness, so as to be safely given even to children and pregnant women, and in inflammatory or acute distempers, where the stimulating purgatives have no place. It is particularly proper in stomachic coughs; in which intentions it is sometimes made up in a linctus or lechoch, with equal quantities of oil of almonds, and syrup of violets. The gripes, flatulencies, and other inconveniences attending it in some constitutions, and when given to adults in large doses, may be obviated by a small addition of some grateful aromatic. Manna does not produce the full effect of a cathartic, unless taken in large doses, as two ounces or more; and, therefore, is seldom employed for this purpose by itself: it may be commodiously dissolved in the purging mineral waters, or sharpened with the cathartic salts, or other purgatives: its efficacy is said to be much promoted by cassia fistularis, a mixture of the two purging more than either of them separately: it is therefore very properly an ingredient in the "electuarium e cassia."

MANNA is also a scripture term, signifying a miraculous kind of food, which fell from heaven, for the support of the Israelites, in their passage through the wilderness; being a small grain, white, like hoar-frost, round and of the size of coriander seeds; its colour like that of bdellium, and its taste like honey.

They call it *manna*, either from the Hebrew word *manab*, a gift, to intimate its being a gift from heaven; or from *minnab*, which signifies to prepare, because the manna came to them ready for eating, and needed no preparation but gathering; or from the Egyptian word *man*, derived from the Hebrew *mab*, what is it? which last etymology seems the more probable, in regard the scripture takes notice of the surprize they were under when they first saw this new food descend. Accordingly the Hebrews, on first seeing this new food which God had provided for them, said to one another *man-hu*, or *mab-hu*, what is this? Others, among whom are Saumaife and many moderns, maintain, that the Hebrews well knew what manna was, and said to one another, *man-hu*, this is manna.

Salmasius, however, prefers another etymology: according to him, the Arabs and Chaldeans used the word *man* to signify a kind of dew or honey that fell on the trees, and was gathered in great abundance on mount Libanus. On which footing the Israelites did not use the term manna out of surprize, but because they found this food fall with the dew, in the same manner as the honey-dew, so well known to them under the name of *man*. Salmasius adds, that the manna of the Israelites was in reality no other than that honey, or dew, condensed; and that the one and the other were the same with the wild honey with which St. John was fed in the wilderness; so that the miracle did not consist in the formation of any new substance in favour of the Israelites, but in the punctual manner in which it was dispensed by Providence for the sustenance of so vast a multitude.

On the contrary, the Hebrews and Orientals believe, that the fall of the manna was wholly miraculous. Whatever was the nature of this substance, which it is not easy, or perhaps possible, for us to ascertain, it was by the dispensation of Providence a nutritive food, and served the children of Israel during their migration in the deserts of Arabia for forty years, from their eighth encampment in the wilderness of Sin. Manna began to fall on Friday morning, the 16th day of the second month, which from thence was called Jiar; and, according to Usher, this was Friday the 5th of June. (Exod. xvi. 14, 15.) It continued to fall daily in the morning, except on the sabbath, till after the passage over Jordan, and to the passover of the 40th year from the Exodus, *i. e.* from Friday the 5th of June, A.M. 2513, to the second day of the passover, Wednesday the 5th of May, A.M. 2553, B.C. 1451. This manna, whatever it was, fell in such quantities, during forty years, as to be sufficient for the sustenance of about a million of persons. Every Friday it fell in a double portion (Exod. xvi. 5.): and though on other days it putrified, if it were kept from one day to another, yet on the sabbath it suffered no such alteration. Thus, the Israelites were instructed in their constant and necessary dependence on the providence of God.

MANNA *Albagina*, a word used by some authors to express that kind of manna called by others *manna mastichina*, from its drops resembling mastic in small tears. It is called *albagina* from the plant which produces it, it being collected from the *albagi maurorum*, in the same manner as the common manna from the Calabrian ash.

MANNA *Libanotis*, in the *Materia Medica*, a name given by the old Greek writers to the small flakes and fragments of the frankincense, which flew off the larger pieces in the gathering and putting them up. See *LEPROS Libanotis*.

MANNA *Mastichina*, a name given by some authors to a kind of manna which they describe as resembling mastic in its colour, and the size of the lumps it is collected in. This is what we usually know at this time under the name of *manna Persicum*, or *Persian manna*, which is even now in use in medicine, in the East, as a common purge.

MANNA *Persicum*, *Persian Manna*. It does not appear in the writings of the ancient Greek physicians, that they were acquainted with any species of manna, though that medicine be now so common in the shops. They had the word indeed, but they applied it to a very different sense; what they called manna being what some authors still called the manna of frankincense, that is such pieces of the common olibanum as broke off in the carriage from the larger pieces. Phil. Transf. N^o 472. p. 86. in vol. xlii.

The Arabians are by some supposed to have first brought what we call manna into use in medicine; but if they were not the absolute inventors of this use of it, it is certain they were the first who made it general and common as a purge. Their country afforded several distinct species of manna, all which seem to have been so common among them, that they thought descriptions of them needless; and for that reason have not left us sufficient accounts of them, from which to determine what were their characters and differences. They distinguished three kinds of this purging medicine, under three absolute different names, which were *manna*, *tereniabin*, and *fracosl*; but it is not easily proved whether these are all now known, or by what appellations they are at this time distinguished.

Rawwolf, in his Itinerary published by Mr. Ray, and Tournefort in his voyage to the Levant, have given the clearest intimations, in regard to this subject, of any of the known writers; and if to these we add Clusius, we have

among the three all that is to be expected of any certainty upon the subject; yet the descriptions of these, though eye-witnesses of all they write, have not prevented so eminent and late a writer as Geoffroy, from falling into an error concerning the manna of the Arabians. It is very evident, however, that we have still one species of the manna Arabum, that is, the *tereniabin*, produced in some parts of the world, there having been specimens of it sent over into England from Peterburgh, near which place it is collected from a plant known among botanical writers under the name of *albagi maurorum*.

This is usually called *manna Persicum*; it appears at first sight a mixed mass of dirty reddish-brown colour, but, upon a nearer view, it is seen to consist of several sorts of particles. First, a great number of globular, crystalline, and almost transparent bodies of different sizes, and of a yellowish-white colour; the biggest of these do not much exceed a larger coriander-seed in size, and they have somewhat the appearance of small lumps of mastic, but are of a somewhat reddish cast. Secondly, there is among these a large quantity of small prickles, and other little woody bodies, which seem to have been the pedicles of leaves. Thirdly, there are a few small leaves which are of firm texture, and terminate in narrow points. Fourthly, there are a large number of small long reddish coloured pods, of a sweetish gelatinous taste, containing from one to six or seven hard, irregular, and kidney-shaped seeds, which to the taste are very four. And fifthly, there is usually some sand and earth among it. Four ounces of this manna dissolved in water usually leave about one ounce of these substances in the filtrate.

The globules first described are something hard, they break between the teeth like sugar-candy, and are of a pleasant sweet taste, but have much less of the manna flavour than the Calabrian, but enough of it to discover to what family the substance belongs: the seeds, sticks, leaves, and pods, seem to be all of them parts of the plant which produces the manna; and the seeds having been sown with us, have raised plants of the albagi. About the year 1537, when Rawwolf wrote his Itinerary, it appears that large quantities of this kind of manna were brought from Perhia to Aleppo, where it was then known by the name of *trunsehibil*, or *trunsehibin*, a corruption doubtless of the word *tereniabin*, or, as it ought to be written, according to Deusingius, *tereng jabin*.

Rawwolf also expressly informs us, that this species of manna was gathered from a plant called *albagi*. This plant is minutely described by Tournefort, who confirms the account of the manna being gathered from it, which Rawwolf had given so long before.

Tournefort says, that it is chiefly gathered about Tauris, a city of Persia, under the name of *trunjibin*, or *terenjabin*, mentioned by Avicenna and Serapion; he adds, that those authors thought it fell upon certain prickly shrubs; whereas it is really the nutritious juice of the plant; and that, during the great heats in that part of the world, there are perceived small round drops, as it were, of honey standing upon the leaves of this plant; and that these harden into globules about the size of coriander-seeds, and are then gathered by the inhabitants, together with leaves, stalks, dirt, and the like foreign matter, which greatly take off from their virtue. M. Tournefort observes, that this manna is greatly inferior to the Calabrian in virtue; and that twenty or thirty drams of it are given for a dose. Philof. Transf. N^o 472, p. 90. ubi supra.

Clusius tells us, that the *tereniabin* of the Arabians is gathered from a prickly shrub, such as the albagi is described

to be; and Avicenna declares, that it was found upon a thorny plant; though his translators have been misled from the near resemblance of two Arabic words, to make it stones, not a plant, that it was gathered from.

It appears very plainly from the whole, that this substance, now known in Russia, and some other parts of the world, under the name of *manna Persicum*, is truly the *terenjabin* of the Arabians and of Clusius, Rawwolf, and Tournefort; only that the word is differently spelt by the latter authors, and it is probably also that manna called by Bauhine, and some other writers, *manna mastichina orientalis*, from the round globules it is composed of resembling the drops of maltich.

MANNA Thuris, the *manna of frankincense*, a term used by the ancient physicians to express such small pieces of frankincense, or olibanum, as broke off from the larger in the carriage. See *LEPTOS Libanotis*.

MANNACOTE, in *Geography*, a town of Kemaon; 60 miles N.W. of Kerigar.

MANNEBACANI, a town of Congo; 40 miles S.W. of Congo.

MANNER, in *Painting*, is not only employed in its natural sense, as designatory of that peculiarity in each painter's mode of composition, drawing, and execution, which, like diversity in hand-writings, characterises the productions of different individuals; but it has also a technical meaning, in which it is commonly employed by artists and connoisseurs, *viz.* to mark certain kinds of deviation from nature in the works of artists, into which, either through conceit or weakness, they have fallen, by endeavouring to obtain that high portion of acknowledged excellence, known by the name of style; of which manner may be considered as the bathos.

The proper application of this word in the art is evident. No two painters have ever executed their works in a manner exactly similar, how nearly soever they may have imitated each other. In every case variety still appears, extending through every portion and principle of their compositions, as well as in their execution of them: just as men think and write differently upon the same subjects, and convey their ideas by dissimilar characters, though tracing the same letters.

It is by this diversity that connoisseurs are enabled to ascertain the authors of pictures, whose names as such would otherwise have been lost: by this the different schools of art are pointed out, and the works of the artists educated in them; although some of superior excellence have varied their manner, in the course of their practice, more than once. Thus, Titian is said to have had his first, second, and third manner; Raphael, his Perugino manner, his own, and that framed in imitation of Michael Angelo. By this, also, the gradual advance of the art may be traced, from its earliest periods, to its arrival at the highest perfection which it attained in the Italian and Flemish schools.

This is the natural and obvious sense of the word; the other is more easily felt than defined. Every artist and amateur, conversant with the necessities and beauties of art, knows and feels that nature is not to be copied at all times, and under every situation. Her works must be selected and imitated only in her happiest moments, in her very best productions. When an artist understands, and can exhibit in his works those peculiarities which exemplify the purity of this select class of natural objects, in all their differing characters, and can avoid the trifling matters which are unnecessary in grand representations, adhering only to that which is truly characteristic, and giving to it all possible truth and force, he has obtained that dignified power which is deno-

minated style. If, in the attempt, he misses his course, and stumbles upon a misconception of true character, and substitutes fanciful perfections of form and colour, which have not the foundation of genuine nature to support them, his style degenerates to manner: being false in its basis, it cannot be ennobled by that higher title, which of necessity implies truth.

Every application of style is indeed a manner; but the latter word is never used for the former, generally in opposition to it, and always derogatory to the artist and his works. For instance, Michael Angelo gave a fulness and grandeur to the form of man in his pictures, which is not to be found so complete in nature. But his perfect knowledge of the nature of the human frame, and the principles upon which it was set in motion, enabled him to apply his peculiar taste of line in a just and characteristic manner; so that though nature appears in his works to be almost extravagantly exerted, still it is not violated: hence the appropriate expression for his works is, that they are wrought in a grand style. His German imitators we speak of as mannerists; because, without comprehending his principles, they imitated his style, only to produce contortions and swellings without character or meaning; muscles in false motions, merely to produce something like what they saw and felt was grand and imposing; a fulness and wave of line, which they carried into parts that ought to have been tranquil, square, or straight: and thus falsifying the style, their art was mannered, drawn from other art, and not from nature.

Art has three stages, as natural to it as childhood, manhood, and age, to man; *viz.* imitation, style, and manner. The first is the sole object which can present itself to the wish of those who attempt to paint, without having any pictures before them; the imitation of a natural object being the proposed end of the attempt. When a man has obtained the power of representing bodies, he naturally seeks for the best and most agreeable subjects for the exercise of his acquired power, and also endeavours to give them as much beauty and interest as possible; this necessarily leads to style: and this, once acquired and exhibited to view, excites others to improve upon and indulge their minds in the ideal gratification which arises from it, and in weak hands produces manner, the bane of the art and artist. One striking difference between style and manner is this: the former may at first sight be unsatisfactory to an uninformed mind, but investigation will gradually increase its value, and heighten it in estimation; the latter, on the contrary, may charm at first sight, but never fails to disgust on a prolonged observation, when its folly and imperfection become apparent. It is an evil which those are always in great danger of being subjected to, who endeavour to make their pictures agreeable, rather than impressive; and forget that the highest praise due to an artist is given only, when he claims it by correctness of force and expression.

A simple imitation may be wrought in a bad or good style: it cannot be said to be mannered, unless some violation of the principles of nature appear introduced, in order to give an ideal improvement upon the natural effect. In drawing, all affectations of square or round, of straight or undulating lines; in colour, all introductions of florid or dull tints, which trench upon the true simplicity of nature; and in expression, all extravagant increase of actions in the features or limbs of a figure, which are not justified by the sentiment intended to be conveyed; all these come under the denomination of manner. These peculiarities are frequently to be found in the works of truly great men; but they are not the less objectionable in principle, and perhaps would

not have been employed by them but to overcome some local disadvantage: in that case, style becomes their proper name. But the want of this consideration has often led students to the admiration of these very defects, and a blind imitation of them, which necessarily generates manner. Thus, Rubens's style of colour is in itself so violent, that, if not fully maintained in all its harmony, it deserves no better title than manner, and becomes completely so in the hands of most of his imitators.

Titian's colour justly merits the most distinguished appellation. It is true to nature, but it is in her simple garb, robbed of her minuter reflections and refractions, yet carefully followed in her general principles, and enriched and heightened by a favourable selection and arrangement of objects, their being placed in agreeable lights, and viewed in a chosen direction. The Venetians carried it to manner: even Tintoretto and P. Veronese, the best and grandest amongst them after Titian and Giorgione. Having imbibed a taste for the rich and luxurious colouring of their predecessors, they could not be content without endeavouring to extend its boundaries; and in so doing, lost sight of nature, and adopted their own fancies as improvements upon her system, and thus sunk in some measure to mannerisms.

It is when the practice of art has become matured by skilful men, that others build systems for their conduct upon the works of their predecessors; and though it is very proper that a system be acted upon, as it greatly facilitates and improves the practice, yet too ready and strict a reliance upon it is almost the certain guide to manner: to avoid which, a constant reference to nature is absolutely necessary. Hence, after the period when M. Angelo, Raphael, Titian, and Corregio, lived and exerted their powerful talents in the perfection of the art of painting, succeeding artists, not endued with their vigour of perception, endeavoured to discover in their works some means of keeping up with them; to establish some system, on which they had or might have proceeded in their extraordinary and beautiful productions: it thence became as much an object to imitate the works of some favourite artist as those of nature; and the true intention of the art, being thus but an accessory rather than a principal, was too often sacrificed. Almost the whole number of the ingenious men who learned in the school of the Caracci, and followed the principles inculcated there, may be properly termed mannerists.

The manner, or the ease which a system gives, of effecting something attractive to the eye, and dazzling to the understanding, is too seductive to be frequently resisted by the inexperienced and vain. Those who have been early taught by system to impose upon themselves, and led to imagine they exhibit great ingenuity in managing a pencil with dexterity, will most likely never believe that it is more difficult, and far more praise-worthy, to think justly, and to imitate attentively the precise terms of an expression, though it be wrought with a heavier hand, and more laborious study. Manner, considered thus, is a kind of receipt for making a picture, a ready mode of combining the necessary ingredients; in which, however, though the hand of the artist may sometimes by accident add a larger or smaller proportion of any one of them, the result is inevitably of nearly the same quality, and is in constant danger of being misapplied: for it is equally as ridiculous to suppose that one kind of execution or mode of composition will suit the representation of all kinds of subjects, as to believe that one composition of medical drugs is adequate to the cure of all kinds of diseases.

MANNERS, in Poetry, denote the inclinations, genius, and

humour, which the poet gives to his persons, and whereby he distinguishes his characters.

Aristotle defines manners to be that which discovers the inclination of him who speaks, and shews what he will resolve upon, or what reject, before he was actually determined: whence he concludes, that manners have not place always, and in all kinds of discourses.

One instance will make this definition clear. In the first book of Virgil, Æneas is represented extremely pious, determined to execute the will of the gods, at all adventures. In the fourth book he has a difficult choice proposed; being engaged, on the one hand, out of a principle of love, gratitude, and honour, not to quit Dido; and having, on the other hand, an express order from the gods to depart for Italy. Now, before it appears on which side he has determined, what he has before said should shew his will and inclinations, and which part he will take. And those preceding discourses, which discover his future resolution, make what we call the poetical manners.

Those make it pait doubt he will abandon Dido to obey the gods; this he does in effect; and the manners, therefore, are good, and well conducted. Had he disobeyed the orders of Jupiter, to stay with Dido, the manners had been ill; because they would have foretold a resolution contrary to what he was really to take. But had there been nothing to make us foresee any resolution of Æneas at all, neither that which he actually took, nor the contrary, in that case there had been no manners at all. It is the manners, as before observed, that distinguish the characters; and, unless the manners be well expressed, we shall never be acquainted with the persons at all; nor, consequently, shall we be either terrified with foreseeing their dangers, nor melted into pity, by seeing their sufferings.

The manners should have four qualities; they should be good, like, suitable, and equal.

The manners are good, when they are well marked or expressed; that is, when the discourse of the persons makes us clearly and distinctly see their inclinations, and what good or evil resolutions they will take. Likeness of manners only relates to known and public persons, whose characters are in history, with which the poetic characters must agree; that is, the poet must not give a person any quality contrary to any of those which history has already given him. And here it may be observed, that the evil qualities given to princes, and great men, ought to be omitted by poets, if they be contrary to the character of a prince, &c. but the virtues opposite to those known vices ought not to be imposed; as by making him generous and liberal in the poem, who was avaricious in the history.

The manners must likewise be suitable; that is, they must be agreeable to the age, sex, rank, climate, and condition of the person that has them. Horace observes, "Intererit multum Davusne loquatur, an heros." Again, the manners must be equal; that is, they must be constant, or consistent, through the whole character; or the variety or inequality of the manners, as in nature, so in the drama, must be equal. The fearful must never be brave, nor the brave timorous; the avaricious must never be liberal, nor vice versa. In this part Shakspeare's manners are admirable.

Besides these four qualities above mentioned, there is a fifth essential to their beauty; which is, that they be necessary; that is, that no vicious quality, or inclination, be given to any poetic person, unless it appear to be absolutely necessary, or requisite, to the carrying on of the action.

MANNERIST, in Painting, one who adopts a manner,

ner in his works, or a peculiar and affected mode of producing effect in them unauthorized by nature.

MANNERSDORFF, in *Geography*, a town of Austria, on the Leytha, celebrated for its medicinal waters; 17 miles S.S.E. of Vienna.

MANNI, GENARO, in *Biography*, composer of the archiepiscopal church, and a great and much respected master at Naples, in 1770: His style of church music much resembles that of Leo, with equal invention and learning. At the death of Jomelli, he formed a plan for a public funeral for that truly great musician, and had interest sufficient to have it executed with uncommon solemnity and splendour. See **JOMELLI**; also **GENARO**.

MANNIFERA ARBOR, in the *Materia Medica*, the name by which the round-leaved ash, on which the manna is found, is often called.

MANNIN BAY, in *Geography*, a small harbour on the W. coast of the county of Galway, Ireland, adjoining that of Ardhear, in which latter there is better anchorage and shelter.

MANNING a HAWK, in *Falconry*, the making her tractable and tame.

MANNING the Fleet, is the providing of it with a sufficient number of men for any expedition. One of the methods commonly resorted to for this purpose is that of impressing men, by warrants from the lord high admiral to the captains, which are by them assigned to their lieutenants; and to render this the more effectual, vessels, called *tenders*, are hired into the service, to proceed from place to place with those officers and press-gangs, not only to receive volunteers, but to impress any seamen whom they find. The power of impressing men for the sea-service by the king's commission, says judge Blackstone, has been a matter of some dispute, and submitted to with great reluctance; though it hath very clearly and learnedly been shewn by sir Michael Foster, that the practice of impressing, and granting powers, to the admiralty for that purpose, is of very ancient date and hath been uniformly continued by a regular series of precedents to the present time: whence he concludes it to be a part of the common law. The difficulty arises from hence, that no statute has expressly declared this power to be in the crown, though many of them very strongly imply it. The stat. 2 Ric. II. c. 4. speaks of mariners being arrested and retained for the king's service, as of a thing well known and practised without dispute; and provides a remedy against their running away. By stat. 2 & 3 Ph. & M. c. 16. if any waterman, who uses the river Thames, shall hide himself during the execution of any commission of pressing for the king's service, he is liable to heavy penalties. By 5 Eliz. c. 5, no fisherman shall be taken by the queen's commission to serve as a mariner; but the commission shall be first brought to two justices of the peace, inhabiting near the sea-coast, where the mariners are to be taken, to the intent that the justices may choose out and return such a number of able-bodied men, as in the commission are contained, to serve his majesty; and by 7 & 8 W. III. c. 21. 2 Ann. c. 6. 4 & 5 Ann. c. 19. 13 Geo. II. c. 17, &c. especial protections are allowed to seamen in particular circumstances, to prevent them from being impressed. And ferrymen are also said to be privileged from being impressed, at common law; all which do most evidently imply a power of impressing to reside somewhere; and, if any where, it must, from the spirit of our constitution, as well as from the frequent mention of the king's commission, reside in the crown alone.

But, beside this method of impressing, which is only defensible from public necessity, to which all private consi-

derations must give way, there are other means tending to the increase of seamen, and for manning the royal navy. Parishes may bind out poor boys apprentices to masters of merchantmen, who shall be protected from being impressed for the first three years; and if they are impressed afterwards, the masters shall be allowed their wages. (2 Ann. c. 6.) Great advantages in point of wages are given to volunteer seamen, in order to induce them to enter into his majesty's service. (1 Geo. II. stat. 2. c. 14.) It is also usual to promise, by proclamation, a bounty to all seamen and able-bodied landmen, who come into the service by a certain time; and every foreign seaman who, during a war, shall serve two years in any man of war, merchantman, or privateer, is naturalized *ipso facto*. 13 Geo. II. c. 3.

About the middle of king William's reign, a scheme was set on foot (7 & 8 W. III. c. 21.) for a register of seamen, to the number of 30,000, for a constant and regular supply of the king's fleet, with great privileges to the registered seamen, and, on the other hand, heavy penalties in case of their non-appearance when called for; but this registry, being judged to be rather a badge of slavery, was abolished by 9 Ann. c. 21. Blackst. Com. vol. i. p. 419, &c.

MANNINGTON, a town of America, in Salem county, New Jersey.

MANNOZZI, GIOVANNI, in *Biography*. See **GIOVANNI DA SAN GIOVANNI**.

MANNUS, MAN, in *Mythology*, the son of the German god Tuiston; of whom, according to Tacitus De Moribus Germanum, these people were descended.

MANO ARMONICA, Ital.; *Main Harmonique*, Fr.; *Harmonic Hand*. See **HAND, Harmonic**.

MANOD, in *Geography*, one of the smaller Philippine islands. N. lat. 12 28. E. long. 122 24'.

MANŒUVRE, To, in *Military Language*, is to manage any body or armed force, as to derive sudden and unexpected advantages before the enemy from superior skill in military movements. It consists in distributing equal motion to every part of a body of troops, that the whole may be enabled to form, or change its position, in the most expeditious and best method, so as to answer the purposes required of a battalion, brigade, or line of cavalry, infantry, or artillery.

MANŒUVRES consist chiefly in those various movements or evolutions, in which soldiers are exercised, in order to fit them for defensive or offensive operations. See **BATTALION, MANUAL and PLATOON Exercises**, and **REVIEW**.

The platoon exercise has been altered as well as the manual. (See **PLATOON** and **BATTALION**.) The exercise is performed a little slower, three seconds being allowed between each motion. It is no longer done by signal, from beat of drum, but all by word of command.

The infantry manœuvres, which were formerly so numerous, are now reduced to 18; which are ordered to be practised and performed in every regiment. The following are the movements, explanations of which, and directions for performing them, are given in the books of exercise. See **BATTALION**.

1. Forming the battalion into close columns in the rear of the right company.
2. Close column in the front of the left company.
3. Close column in a central company, facing to the rear.
4. Changing position in open column.
5. Throwing back the wings.
6. Changing position by a counter-march.
7. Counter-marching by files in the centre of the battalion.
8. Marching in open column.
9. Echelon change of position.
10. Taking up a new line by the echelon movement.
11. Changing position to right or left.
12. Retreating in line.
13. Marching to a flank in echelon.

on. 14. Forming the hollow square. 15. Retiring in line and filing. 16. Advancing in line, filing, and charging to the front. 17. Retreating in line. 18. Advancing in line.

MANOK MANKA, in *Geography*, an island in the Sooloo Archipelago. N. lat. $4^{\circ} 54'$. E. long. $119^{\circ} 48'$.

MANOMETER is the name of an instrument in experimental philosophy; it is derived from $\mu\alpha\upsilon\sigma\iota\varsigma$, *rare*, and $\mu\epsilon\tau\epsilon\omicron\rho\iota\varsigma$, *measure*, being intended to measure the rarefaction and condensation of elastic fluids in confined circumstances, whether occasioned by variation of temperature, or by the actual destruction or generation of portions of elastic fluid. It is sometimes called *manoscope*.

Mr. Boyle's *statical barometer* was an instrument of this kind; it consisted of a bubble of thin glass, hermetically sealed, about the size of an orange, which being counterpoised when the air was in a mean state of density, by means of a nice pair of scales, sunk when the atmosphere became lighter, and rose as it grew heavier. This instrument would evidently indicate the changes of *density* of the atmosphere; but it leaves us uncertain as to the cause, whether it is from a change of its *weight*, or of its *temperature*, or of both. See BAROMETER, *Statical*.

The manometer constructed by Mr. Ramsden, and used by Captain Phipps, in his voyage to the North Pole, was composed of a tube of a small bore, with a ball at the end; the barometer being at 29.7, a small quantity of quicksilver was put into the tube, to take off the communication between the external air, and that confined in the ball and the part of the tube below this quicksilver. A scale is placed on the side of the tube, which marks the degrees of dilatation arising from the increase of heat in this state of the weight of the air, and has the same graduation as that of Fahrenheit's thermometer, the point of freezing being marked 32. In this state, therefore, it will shew the degrees of heat in the same manner as a thermometer. But if the air becomes lighter, the bubble inclosed in the ball, being less compressed, will dilate itself, and take up a space as much larger as the compressing force is less; therefore the changes arising from the increase of heat will be proportionably larger; and the instrument will shew the differences in the density of the air, arising from the changes in its weight and heat. Mr. Ramsden found, that a heat equal to that of boiling water, increased the magnitude of the air from what it was at the freezing point $\frac{1}{20}$ of the whole. Hence it follows, that the ball and the part of the tube below the beginning of the scale is of a magnitude equal to almost 414 degrees of the scale. If the height of both the manometer and thermometer be given, the height of the barometer may be thence deduced by this rule; as the height of the manometer increased by 414 is to the height of the thermometer increased by 414, so is 29.7 to the height of the barometer.

In the 67th volume of the Philosophical Transactions for 1777, page 689, Col. William Roy has given a description of the manometers he used to ascertain the expansion and contraction of dry and moist air by change of temperature. "They were of various lengths, from four to upwards of eight feet; they consisted of straight tubes, whose bores were commonly from $\frac{1}{7}$ th to $\frac{1}{2}$ th of an inch in diameter. The capacity of the tube was carefully measured, by making a column of quicksilver, about three or four inches in length, move along it from one end to the other. These spaces were severally marked with a fine edged file on the tubes, and transferred from them to long slips of pasteboard, for the subsequent construction of the scales respectively belonging to each. The bulb attached to one end of the manometer at the glass-house, was of the form of a pear, whose point

being occasionally opened, dry or moist air could be readily admitted, and the bulb sealed again, without any sensible alteration in its capacity.

"The air was confined by means of a column of quicksilver, long or short, and with the bulb downward or upwards, according to the nature of the proposed experiment. Here it must be observed, that from the adhesion of the quicksilver to the tube, the instrument will not act truly, except it be in a vertical position; and even then it is necessary to give it a small degree of motion, to bring the quicksilver into its true place, where it will remain in equilibrium, between the exterior pressure of the atmosphere on one side, and the interior elastic force of the confined air on the other.

"Pounded ice and water were used to fix a freezing point on the tube; and by means of salt and ice, the air was farther condensed, generally four, and sometimes five or six degrees below zero. The thermometer and manometer were then placed in the tin vessel, among water, which was brought into violent ebullition; where having remained a sufficient time, and motion being given to the manometer, a boiling point was marked thereon. After this the fire was removed, and the gradual descents of the piece of quicksilver, corresponding to every 20 degrees of temperature in the thermometer, were successively marked on a deal rod applied to the manometer. It is to be observed that both instruments, while in the water, were in circumstances perfectly similar; that is to say, the ball and bulb were at the bottom of the vessel.

"In order to be certain that no air had escaped by the side of the quicksilver during the operation, the manometer was frequently placed a second time in melting ice. If the barometer had not altered between the beginning and end of the experiment, the quicksilver always became stationary at or near the first mark. If any sudden change had taken place in the weight of the atmosphere during that interval, the same was noted, and allowance made for it in afterwards proportioning the spaces.

"Long tubes, with bores truly cylindrical, or of any uniform figure, are scarcely ever met with. Such, however, as were used in these experiments, generally tapered in a pretty regular manner from one end to the other. When the bulb was downwards, and the tube narrowed that way, the column of quicksilver confining the air lengthened in the lower half of the scale, and augmented the pressure above the mean. In the upper half, the column being shortened, the pressure was diminished below the mean. In this case the observed spaces, both ways from the centre, were diminished in the inverse ratio of the heights of the barometers at each space, compared with its mean height. If the bore widened towards the bulb when downwards, the observed spaces each way from the centre were augmented in the same inverse ratio; but in the experiments on air less dense than the atmosphere, the bulb being upwards, the same equation was applied with contrary signs; and if any extraordinary irregularity took place in the tube, the corresponding spaces were proportioned both ways from that point, whether high or low, that answered to the mean.

"The observed and equated manometrical spaces being thus laid down on the paste-board containing the measures of the tube; the 212° of the thermometer, in exact proportion to the sections of the bore, were constructed along side of them; hence the coincidences with each other were easily seen; and the number of thermometrical degrees answering to each manometrical space readily transferred into a table prepared for the purpose." For the important results obtained by these instruments, see BAROMETER, *Measurement of Altitudes*.

It may not be amiss to observe that Colonel Roy's results on the expansion of dry air have been generally confirmed by the subsequent experiments of Dalton and Gay Lussac; but those on moist air have been found less satisfactory, unless in such cases when water in a liquid state is present. Mr. Dalton has given a theorem, derived from his experience, to ascertain the expansion of moist air (that is, when water is present in the liquid state) for any temperature. Supposing the space occupied by the dry air at the given temperature to be 1, the atmospheric pressure = p , and f = the force of steam at the temperature; then the space of the moist air will

$$be = \frac{p}{p - f}.$$

The striking peculiarity of manometers of the above construction, and that on which their chief excellence depends, is that a mercurial column of about $\frac{1}{15}$ th or $\frac{1}{20}$ th of an inch in diameter, slides freely up and down a glass tube, without suffering any air to pass either way. This character is, however, obtained only by preserving the tube and mercury very clear and dry. If any dust, moisture, or oxyd be found in the tube, the mercury becomes less free in its motion, and the air is apt to break the mercurial column, and gradually escape. A bore of less diameter would occasion too much friction, and one of greater would suffer the mercury to fall down.

When the expansion or dilatation of the air in any experiment amounts to one-half of the original volume, or any other quantity exceeding that, a manometer of a still more simple construction may be used, namely, a straight tube, or one without bulb, of the same bore or capacity as Col. Roy's. It must be divided into equal spaces, by means of a sliding mercurial column, on account of the irregularity of the bore incident to such tubes; a small drop of mercury may then be let down by a clean iron wire to any part of the tube, so as to constitute a sliding column of about half an inch in length.

Another species of manometer may be used when the object is to measure the force of steam or vapour, generated over certain liquids by heat. In this case a tube similar to the preceding may be bent into a siphon with parallel legs, the shorter leg of which must be closed, or hermetically sealed, and the longer open. A few drops of the liquid must be conveyed to the extremity of the closed leg; after which the greater part of the tube may be filled with mercury, so as to leave no space with air between the mercury and the liquid; the manometer must then be put into water, &c. of a known temperature, and held in a perpendicular posture, with the bending lowest, and so that the extremity of the tube containing the liquid may be wholly immersed in the warm water, whilst the other extremity is without. The heat will expand part of the liquid into steam, which will depress the mercury in the same leg, and elevate it in the opposite, till an equilibrium of pressure is established. The elastic force of the steam will evidently be equal to the pressure of the atmosphere \pm the difference of the heights of the two mercurial columns in the siphon, according as the column in the open or closed leg exceeds that of the other. If the difference of the heights is expected to be upwards of thirty inches, some inconvenience arises from the great length of tube requisite: in this case an ingenious contrivance has been invented to obviate it; the open end of the manometer must be hermetically sealed, so as to inclose a column of atmospheric air of due volume; when the steam is formed in the liquid, and the mercury depressed, it condenses the air in the other leg, and the space occupied by the condensed air, as is well known, is inversely as the force;

then the quantity of this force thus ascertained \pm the difference of the two mercurial columns, will give the whole elastic force of the steam. Great care must be taken that the air-column of the siphon is clear of the liquid that generates the steam. By this sort of instrument Mr. Dalton finds the force of steam from sulphuric ether at 212° Fahr. = 236 inches of mercury. See Manchester Mem. vol. v. p. 567. Also, New System of Chemistry, part 1, p. 14.

The straight tube manometer is the most elegant and simple instrument to prove the important property of elastic fluids above alluded to, namely, that the space occupied by any permanent elastic fluid is inversely as the pressure. For this purpose a small given portion of air is confined in the bottom of a long tube, of forty inches or more. A column of twenty-five inches, more or less, of mercury is admitted into the tube to confine the air; when the tube is held horizontally, the confined air is pressed by the atmosphere only: when the tube is held perpendicular, the air has the pressure of the atmosphere + that of the mercurial column; and when it is held downwards, the air has the pressure of the atmosphere — that of the mercurial column. By marking the spaces occupied by the air in these circumstances, they are found to be inversely as the pressures.

Saussure, in his Essays on Hygrometry, describes his manometer: it was nothing but an ordinary barometer: a simple straight tube was filled with boiled mercury, and its open end was immersed in a cup of the same liquid; the whole was then inclosed in a large glass balloon, except a few inches of the upper extremity of the tube, to which a scale of degrees or equal parts was attached, to shew the variation of the altitude of the mercury. The tube passed through a circular hole in a tin plate which covered the opening of the balloon, and which was very carefully luted, as was the passage of the tube, so as to be perfectly air-tight. In this case it was evident the instrument was no longer a barometer, as it was cut off from the action of the air out of the balloon; but the mercury was supported by the spring or elasticity of the air within the balloon, and must be subject to such fluctuations as took place in it, independently of any change of weight in the atmosphere. By means of this apparatus, Saussure found that atmospheric air, in passing from extreme dryness to extreme moisture, in the temperature of 65° Fahr., increased about $\frac{1}{3}$ th in elasticity; and *vice versa*, in passing from extreme moisture to extreme dryness, it diminished $\frac{1}{3}$ th in its elastic force, the temperature being all the time uniform.

MANONOETOC, in *Natural History*, a name given by the people of the Philippine islands to a species of horned owl, common in those parts.

MANOOR, in *Geography*, a town of Hindoostan, in the province of Dindigul; 27 miles N.W. of Dindigul.

MANOORGUDY, a town of Hindoostan, in the circar of Mahur; 20 miles N. of Neermul.

MANOR, or MANNOR, an ancient lordship, or royalty; consisting of demesnes and services, and of a court-baron, as incident thereto.

The word is formed from the French *mancier*, a *manfion-house*; and that from the Latin *manere*, to remain or dwell; as being the lord's usual place of residence.

Manor is the same with what was formerly called *baronia*, *barony*; as it is still called *lordship*; and lord or baron was empowered to hold a domestic court, called the "court-baron," for redressing misdemeanors and nuisances within the manor, and for settling disputes of property among the tenants. This court is an inseparable ingredient of every manor; and if the number of suitors should so fail as not to

leave

leave sufficient to make a jury or homage, that is, two tenants at the least, the manor itself is lost.

A manor is a kind of noble fee, granted out partly to tenants, for certain services to be performed, and partly reserved to the use of the lord's family; with jurisdiction over his tenant, for the lands, or estates, held of him. As to the original of manors, we are told there was anciently a certain compass of ground, granted by the king to some man of worth, for him and his heirs to dwell upon, and to exercise some jurisdiction, more or less, within that circuit, such as he thought good to grant; but performing such services, and paying such yearly rent, as by this grant was required. Now the lord afterwards parcelling the same to other meaner men, received rent and services from them, and by that means, as he became tenant to the king, the inferiors became tenants to him. The superior lord, under whom the smaller manors continue to be held, is called, in such cases, the lord paramount over all these manors; and his feignory is frequently termed an honor, not a manor, especially if it hath belonged to an ancient feudal baron, or hath been at any time in the hands of the crown. In process of time the inferior lords parcelled out and granted to others more minute estates, to be held of themselves, and so downwards without limit; till at length their superior lords observed, that by this method of subinfeudation they lost all their feudal profits, of wardships, marriages, and elcheats, which fell into the hands of these mesne or middle lords, who were the immediate superior of the "terre-tenant," or occupier of the land; and also that the mesne lords themselves were so impoverished thereby, that they were disabled from performing their services to their own superiors. This occasioned, first, that provision in the 32d chapter of Magna Charta, 9 H. III. (which is not to be found in the first charter granted by that prince, nor in the great charter of king John,) that no man should either give or sell his land, without reserving sufficient to answer the demands of his lord; and afterwards the statute of Westm. 3, or "quia emptores," 18 Edw. I. c. 1, which directs, that, upon all sales or feoffments of land, the feoffee shall hold the same, not of his immediate feoffor, but of the chief lord of the fee, of whom such feoffor himself held it. But these provisions, not extending to the king's own tenants *in capite*, the like law concerning them is declared by the statutes of "prerogativa Regis," 17 Edw. II. c. 6, and of 34 Edw. III. c. 15, by which last all subinfeudations, previous to the reign of king Edward I., were confirmed; but all subsequent to that period were left open to the king's prerogative. And from hence it is clear, that all manors existing at this day, must have existed as early as king Edward I.; for it is essential to a manor, that there be tenants who hold of the lord; and by the operation of these statutes, no tenant *in capite* since the accession of that prince, and no tenant of a common lord since the statute of "quia emptores," could create any new tenants to hold of himself.

At this time a manor rather signifies a jurisdiction, and royalty incorporeal, than the land and suit: for a man may now have a manor in gross, *i. e.* the right and interest of a court baron, with the perquisites, and another enjoy every foot of land belonging to it.

A manor may be compounded of divers things: as of an house, arable land, pasture, meadow, wood, rent, advowson, court-baron, &c. And this ought to be, by long continuance of time, beyond man's memory.

It is held by some, that a manor cannot now be made, since a court-baron cannot be made; and without a court-baron, and at least two suitors, there can be no manor. A manor may contain one or more villages or hamlets, or only a great

part of a village; and there are capital manors or honors, which have other manors under them, the lords whereof perform customs and services to the superior lords. There may be also customary manors, granted by copy of court roll, and held of other manors. But it cannot be a manor in law, without freehold tenants; nor a customary manor, without copyhold tenants. The custom remains, when tenements are divided from the rest of the manor, the tenants paying their services; and he who hath the freehold of them may keep a court of survey, &c. See VILLEIN, COPYHOLD, and TENURE.

MANOR Courts are such as are held within the manor, for the purpose of adjusting the various rights, claims, &c. It is observed that the business of holding these, depends on whether they are held of right, or merely by custom. It is added, that "if the copyhold tenure is so far worn out, in any manor, that there are not two ancient or feudal tenants remaining within it, the court has lost its legal power. It cannot by right take cognizance of crimes, nor enforce amerancements." It is, however, allowed that manorial courts have their uses, in regulating farm-roads, drift-ways, and water-courses, and in preventing nuisances of different kinds within a manor, and it is generally right to preserve the custom of holding them for these purposes. Where copyhold courts remain in force, and where legal forms are to be observed, they are best held by a law steward.

MANOR, in *Geography*, a township of America, in Lancaster county, Pennsylvania, containing 1804 inhabitants.

MANORCOTTA, a town of Hindoostan, in Madura; 15 miles N. of Coilpatta.

MANORE, a town of Hindoostan, in Baglana; 38 miles S. of Damaun.

MANOR-HAMILTON, a small post-town of the county of Leitrim, Ireland, on the road to Sligo; being near 11 miles east of that town, and 94 miles N.W. from Dublin.

MANORIAL CLAIMS, the claims which the lords of manors have upon their tenants, and which are different in different cases, according to the nature of the manor. In respect to the appropriation of commonable lands, these claims should, according to a late writer, be regulated by the particular advantages which the lord of a given manor may enjoy, and which he may continue to enjoy, while they remain open and uninclosed, whether they may arise from mines, quarries, water, alien tenants, fuel, estover, pannage, game, &c. The claims of lords, as guardians of the soil, which is productive of *pasturage* only, is, in most instances, merely honorary; and it is for the legislature to apportion the share of lands, to which they are entitled, as an equivalent for such. But their claims, in the right of the soil on which *thriving timber* is standing, are more substantial; as out of these, they have in effect a real yearly income, equal to the annual increasing value of the timber; a sort of advantage which they of course will continue to enjoy, if the commons remain open and uninclosed, as long as the timber continues to increase in value. Their claims in this respect, consequently depend on the quantity of timber, and its state of growth, conjointly taken. It is supposed that, "young thriving timber, not only affords an annual increase of value at present, but will continue its benefits for many years to come, if it be suffered to remain undisturbed, or the soil which supports it, during the estimated period of its future increase; whereas dotards and stunted trees, which afford no increase of value, do not entitle their owners to any share of the soil they stand upon; the trees themselves, or their intrinsic value, appear to be all that the lord has a right to claim."

It is conceived that the claims of the crown, or of hereditary rangers on forest lands, should be satisfied on the same principle.

MANORPOUR, in *Geography*, a town of Hindoostan, in Mewat; 25 miles S.W. of Cottilah.

MANOS, a town of the island of Cuba; 20 miles E.N.E. of Havannah.—Also, a cluster of small islands in the Spanish Main, near the coast of Darien. N. lat. $9^{\circ} 17'$. W. long. $78^{\circ} 40'$.

MANOSQUE, a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of Forcalquier, which, before the revolution, was the residence of a governor, and contained seven churches and a commandery of Malta; near it is a medicinal spring; seven miles S. of Forcalquier. The place contains 5360, and the canton 11,527 inhabitants. N. lat. $44^{\circ} 50'$. E. long. $5^{\circ} 51'$.

MANOT, a town of Hindoostan, in Aurungabad; 60 miles E.S.E. of Aurungabad.

MANOU, a kingdom of Africa, E. of Quoja.

MANOUARAN, a small island in the North Pacific ocean, near the N. coast of Waygoo. N. lat. $0^{\circ} 6'$. E. long. $131^{\circ} 10'$.

MANPOUR, a town of Hindoostan, in Benares; 12 miles N.W. of Bidzigur.—Also, a town of Hindoostan, in Bahar; 35 miles S.W. of Bahar.—Also, a town of Hindoostan, in Oude; 40 miles S.E. of Gorrackpour.

MANQUES SECAS, a cluster of small islands in the Atlantic, near the coast of Brazil. S. lat. $2^{\circ} 25'$. W. long. $44^{\circ} 50'$.

MANQUES Verdes, a cluster of small islands in the Atlantic, near the coast of Brazil. S. lat. $2^{\circ} 25'$. W. long. $44^{\circ} 46'$.

MANRESA, **MINOROSA**, or *Manxes*, a town of Spain, in Catalonia, which gives name to a viguier, *i. e.* governed by a viguier (*vicarius*) or jurisdiction, situated on a river, which soon after runs into the L'Obregat; it is defended by a castle, and contains several convents; 25 miles N.N.W. of Barcelona. N. lat. $41^{\circ} 44'$. E. long. $1^{\circ} 44'$.

MANRIQUE, **D. JORGE**, in *Biography*, a Spanish poet of the old school, who has retained, to the present period of time, a large share of popularity, and who flourished in the fifteenth century. He is chiefly celebrated for the forty-two stanzas upon the death of his father, which are so natural, and which, being upon a subject that interests every breast, are read with pleasure by all persons from the throne to the friar's cell; they have been frequently reprinted with paraphrases and commentaries. The other pieces of this poet are to be found in the "Cancionero." It was affirmed by Joam II. of Portugal, that it was as necessary for a man to know these stanzas by heart, as to know the pater-noster. Gen. Biog.

MANS, LE, in *Geography*, a city of France, and capital of the department of the Sarthe, and chief place of a district, situated at the conflux of the Huifne and Sarthe. Before the revolution it was the capital of Lower Maine, the see of a bishop, the seat of a governor, an electorate, bailiwick, &c. and contained a cathedral, two collegiate, 13 parish churches, and 12 religious houses. It is divided into two parts, one containing 9366, and the other 7855 inhabitants. The canton of the former contains 13,866, and that of the latter 11,534 inhabitants; on a territory of 140 kilometres, in 16 communes. N. lat. 48° . E. long. $0^{\circ} 17'$.

MANSALA, a town of Sweden, in the province of Nyland; 21 miles N. of Borgo.

VOL. XXII.

MANSAPÉ, a town of Lower Siam, near the coast. N. lat. $13^{\circ} 15'$. E. long. $102^{\circ} 20'$.

MANSARA, a town of Hindoostan, in Bahar; 13 miles S. of Durbungah.

MANSAROAR, a lake of Thibet, about 115 miles in circumference, whence springs the southern branch of the Ganges.

MANSART, FRANCIS, in *Biography*, an eminent French architect, born at Paris in 1598, was son of the king's carpenter, and received those instructions which led him to eminence, as an architect, from the celebrated Gautier; but for the high rank to which he attained in his profession, he was indebted to the force of his own genius. His taste and judgment, united with a fertile imagination and sublime ideas, enabled him to equal the greatest masters in his plans; he was, however, too apt to alter his designs, and even, in aiming at perfection, to demolish what was already not only well done, but scarcely to be surpassed. This character was the means of preventing him the honour of finishing the fine abbey of Val-de-Grace, founded by Anne of Austria, which he had commenced in 1645, and which, when raised to the first story, the queen put into other hands, to prevent its destruction by him who had reared it. He was employed by the president Longueuil to build his great château de maisons, near St. Germain's; and when a considerable part of it was erected, he pulled it down again without acquainting the master with his intentions. After this, it is to his credit, that he finished it in a very noble style, and it is reckoned one of the finest architectural monuments of that age. A better idea cannot be given of his character than this; Colbert applied to him for a design of the principal front of the Louvre, and Mansart produced many sketches of great beauty, but when told he must fix upon one to be invariably followed, if approved, he declined the business. His last great work was the portal of the Minims in the Place Royale; he died in 1666, at the age of sixty-nine. He is known as the inventor of a particular kind of roof called the *mansarde*. He had a nephew Jules-Hardouin, who was also eminent in his profession as an architect, and was educated by his uncle. He became a favourite of Lewis XIV. and was enabled, under his patronage, to realize a large fortune. Some of his principal works were the château de Clagny; the palace of Versailles; the house of St. Cyr; the gallery of the Palais Royal; the palaces of Louis-le-Grand, and des Victoires, and the dome and finishing of the "Invalides." He died suddenly at Marly in the year 1708.

MANSBY, in *Geography*, a town of Sweden, in West Bothnia, on the Calix; 25 miles W.N.W. of Tornea.

MANSCOUE, a bailiwick in Georgia, S. of the Muscogee shoals, in the Tennessee river, remarkable for the mammoth bones found here.

MANSDORF, a town of Prussia, in Pomerelia; seven miles N. of Marienburg.

MANSE, **MANSUS**, *Manfa*, or *Manfum*, formed a *manendo*, *abiding*, as being the place of dwelling, or residence, in ancient *Law-Books*, denotes a house or habitation; either with or without land.

MANSE, *Capital*, *mansum capitale*, denotes the manor-house or lord's court.

MANSE, or *Mansus presbyteri*, is a parsonage or vicarage-house, for the incumbent to reside in.

This was originally, and still remains, an essential part of the endowment of a parish-church, together with the glebe and tithes. It is sometimes called *presbyterium*.

MANSEL, in *Geography*, an island in the N.E. part of

Hudson's bay, between Southampton island and the coast of Labrador. N. lat. 62° 38'.

MANSERET, a town of Spain, in the Asturia of Oviedo.

MANSFELD, PETER ERNEST, *Count de*, in *Biography*, a German statesman and commander: in 1552 he was made prisoner at Ivoy, which place he governed. He afterwards became governor of Luxemburg, where he maintained tranquillity, while the rest of the Low Countries was in a state of civil war. He had afterwards the entire command of Brabant. He died at the advanced age of 87, in the year 1604. Moreri.

MANSFELD, ERNEST, *Count of*, a celebrated general, born in 1585, was the natural son of the foregoing Peter Ernest, count of Mansfeld. He was brought up at the court of the archduke Ernest, governor of the Low Countries, who sent him at an early age into Hungary, to learn the art of war under his brother Charles. He served the emperor and the king of Spain in Hungary and the Low Countries, and was legitimated by the former, on account of his bravery. He received some slights from the Spanish government, which caused him to quit its service in disgust, and he entered into that of the duke of Savoy. He had been brought up in the Catholic religion, but did not scruple to enter into the league of the Protestant princes against the head of the empire, and henceforth he became one of the most formidable enemies of the house of Austria. He was sent by Frederic, elector palatine, in 1618, into Bohemia, to support the revolters from the authority of the emperor. The Bohemians appointed him grand-master of artillery and general of infantry; he took Pilsen, and gained other advantages. After Frederic, who had been elected king, had lost the battle of Prague in 1620, Mansfeld kept on the war till he was compelled by the superior forces of Tilly to retire into the palatinate. His heroism was now every where celebrated, and though lying under the ban of the empire, without estate or property of any kind, he had rendered his name so famous by his spirit of enterprize, and his singular faculty of recruiting after losses, and keeping the field though often defeated, that he found himself courted at the same time by the king of France, the French Protestants, the kings of Spain and England, and the republics of Holland and Venice. He determined, however, to join the duke of Bouillon, and the reformed party in France, and performed many feats of surprising valour. When he had disbanded his troops he visited France and England, and from the latter country he obtained troops, with which he assisted the prince of Orange to raise the siege of Breda. In 1625 he returned to Germany, and after ravaging the archbishopric of Cologne, joined the king of Denmark in Lower Saxony; a train of ill success now pursued him, and he was anxious to try his fortune at Venice; with this view he set out, accompanied by twelve officers, although at that time labouring under a slow fever. He, however, passed through Servia and Bosnia, and arrived in Dalmatia, but with such an increase of his disorder, that he was obliged to stop at a village near Zara. There, finding his end approaching, he exhorted his companions to remain true to the liberty of their country, and tranquilly expired in November 1626, at the age of forty-one. He had every quality of a great captain, and he always acted with fidelity and indefatigable zeal in the service of the party whose cause he espoused. The want of regular authority, and resources, obliged him to connive at the disorders committed by his soldiers; and his marches were sometimes so destructive, that the house of Austria named him the "Attila of Christendom." Moreri. *Mod. Univer. Hist.*

MANSFELD, in *Geography*, a town of Westphalia, in the county of Mansfeld, having a castle on a high rock, which was formerly a fortress, and the residence of the counts of Mansfeld, now in a considerably dilapidated state; 36 miles N.N.E. of Erfurt. N. lat. 51° 38'. E. long. 11° 41'.

MANSFELD, *County of*, a principality of Westphalia, bounded by the electorate of Saxony and Querfurt, the diocese of Merseburg and the duchy of Magdeburg, the principalities of Anholt and Halberstadt, and the county of Stolberg. Its greatest length is 28, and greatest breadth 16 miles. Although it is generally mountainous, it affords good corn land and pasturage, with a considerable extent of woods, vineyards, chaces, and fisheries; besides a salt-work and mine, and a slate from which copper is extracted. This slate bears impressions of all kinds of animals, especially of fishes. In this county are also two lakes, almost contiguous and communicating with each other; and yet the water of the one is salt, and that of the other fresh and sweet. These lakes abound with fish, which furnish employment and subsistence for the adjoining inhabitants. They supply also a great number of wild-ducks, geese, snipes, and other water-fowl. The county contains seven towns. The prevalent religion is Lutheranism, introduced into the country by the activity and zeal of Albert VII., count of Mansfeld. This county is partly a fief of Saxony and Magdeburg. At the peace of Tilist, the Prussian part of this county was annexed to Westphalia.

MANSFELD, a town of Prussia, in Natangen; 10 miles S.S.W. of Königsberg.

MANSFIELD, EARL OF, in *Biography*. See MURRAY.

MANSFIELD, in *Geography*, a market town and parish in the wapentake of Broxtow, Nottinghamshire, England, is situated in the forest of Sherwood, at the distance of 14 miles from Nottingham, and 138 from London. It appears to have been a place of high antiquity; coins of several Roman emperors have been found in and near the town; and the recent discovery of ancient relics near Mansfield Woodhouse is an indisputable proof that the Romans had a station or settlement in this vicinity. In the Domesday survey "Maunfield," as it was anciently called, is mentioned as a royal manor; and successive monarchs have granted several privileges to it. A market was established by a charter of Henry III.; and a fair by a grant from Richard II. When Sherwood forest was a royal chace, here was a royal villa which the sovereigns kept as a hunting seat; and, to use the words of an old inquisition, "Henry Fauconberge held the manor of Cuckney, in serjeantry by the service of shoeing the king's palfrey when the king came to Mansfield." Leland's account of this place is not very favourable; he calls it "a little pore street, a thoroughfare at the end of the wood;" but at present it is a large and opulent town; the houses, which are in general well built, were stated in the population return of the year 1800, to be, in number, 1245, and occupied by 5998 persons. The market, which is held on Thursdays, is generally well stocked with corn and cattle; and here are now three annual fairs, chiefly for cattle and cheese. Several considerable manufactories are established here; a great trade in free-stone is carried on with Nottingham; and the malting business is very extensive. The church is a commodious structure; and here is a respectable free-school, with two scholarships at Jesus college, Cambridge, founded by queen Elizabeth in the third year of her reign.

At the distance of a mile and half from the town, is the township and chapelry of Mansfield Woodhouse, which contains

tains 211 houses, and 1112 inhabitants. In the year 1786, Hayman Rooke, esq. of this place discovered, within about a mile from the village, two Roman villæ, which he called Urbana and Rustica; the former containing nine rooms, the latter thirteen; with hypocausts, baths, and other appendages: the walls of most of the rooms appeared to have been stuccoed, and painted in stripes of various colours; and in the centre-room of the Urbana was a tessellated pavement. Mr. Rooke also found the remains of two Roman sepulchres, with urns, bones, &c.: and various fragments of pateræ and pots of Roman ware, with other relics of antiquity, were discovered in the rooms of the villæ.

Within a few miles from Mansfield are several magnificent mansions, viz. Worktop, the seat of the duke of Norfolk; Clumber, the duke of Newcastle's; Thoresby, lord Newark's; and Welbeck, belonging to the duke of Portland. In popular language this part of the country is called the dukery, from the number of seats belonging to dukes. History of Nottinghamshire, by Thoroton and Throsby, three vols. 4to. 1797.

MANSFIELD, a township of America, in Suffolk county, New Jersey, situated on Muffonenunk river, about seven miles S. E. of Oxford, and containing, in 1790, 1482 inhabitants.—Also, a township in Bristol county, Massachusetts, 29 miles southerly of Boston, incorporated in 1770, and containing 1016 inhabitants.—Also, a township in Chittenden county, Vermont, between La Moille and Onion rivers, about seven miles from each, and 183 miles N. by E. from Bennington. Mansfield mountain rises in this town. Its inhabitants are 12.—Also, a township in Burlington county, New Jersey, on the S. side of Black's creek, consisting of 19,000 acres of excellent soil, noted for its fine pastures and large dairies; eight miles W. by N. from Burlington. The inhabitants are for the most part Friends.—Also, a township in Windham county, Connecticut, about 30 miles N. of New London; containing 2560 inhabitants.

MANSIATRE, a river on the W. coast of Madagascar, which runs into the strait of Mozambique. S. lat. 19° 45'.

MANSIELLA, a town of Spain, in the province of Leon; 10 miles S. E. of Leon.

MANSION, MANSIO, a *manendo*, a dwelling-house, or habitation, especially in the country.

Among the ancient Romans, *mansio* was a place appointed for the lodging of the princes, or soldiers, in their journey; and in this sense we read *primam mansionem*, &c. It is with us most commonly used for the lord's chief dwelling-house within his fee; otherwise called the capital messuage or manor place: and mansion-house is taken in law for any house or dwelling of another; in case of committing burglary, &c.

MANSIO, or *Manfus*, was sometimes also used in the same sense with *hide*; that is, for as much land as one plough could till in a year.

MANSLAUGHTER, in *Law*, is a species of felonious homicide, and denotes the unlawful killing of a man, without any malice, either express or implied; which may be either voluntarily, upon a sudden heat; or involuntarily, but in the commission of some unlawful act. (1 Hal. P. C. 466.) As when two persons, who before meant no harm to one another, falling out on some sudden occasion, the one kills the other; this is voluntarily manslaughter. But in this and every other case of homicide upon provocation, if there be a sufficient time for passion to subside, and reason to interpose, and the person provoked afterwards kills the other, this is deliberate revenge, and amounts to murder. (Foll. 296.) Thus, if a man takes another in the act of adultery with his wife, and kills him directly upon the spot; though this was

allowed by the laws of Solon, as likewise by the Roman civil law, (if the adulterer was found in the husband's own house,) and also among the ancient Goths; yet in England it is not absolutely ranked in the class of justifiable homicide, as in the case of a forcible rape; but it is the lowest degree of manslaughter; and therefore in such a case the court directed the burning in the hand to be gently inflicted, because there could not be a greater provocation. (1 Hal. P. C. 486. Sir T. Raym. 212.) Manslaughter, therefore, on a sudden provocation differs from excusable homicide *se defendendo* in this; that in one case there is an apparent necessity for self-preservation, to kill the aggressor; in the other no necessity at all, being only a sudden act of revenge. Farther, if two persons play at sword and buckler, unless by the king's command, and one of them kills the other, this is *involuntary* manslaughter, because the original act was unlawful. (3 Inst. 56.) So where a person does an act, lawful in itself, but in an unlawful manner, and without due caution and circumspection; as when a workman flings down a stone or piece of timber into a street, and kills a man; this may be either misadventure, manslaughter, or murder, according to the circumstances attending it: if it were in a country village, and he calls out to all people to have a care, it is misadventure only; but if it were in London, or other populous towns, where people are continually passing by, it is manslaughter, though he gives loud warning (Kel. 40.); and murder, if he knows of their passing, and gives no warning at all; for then it is malice against all mankind. (3 Inst. 57.) The crime of manslaughter amounts to felony, but within the benefit of clergy; and the offender shall be burnt in the hand, and forfeit all his goods and chattels. By a law of king Canutus, if a man is killed openly and premeditatedly, the murderer shall be committed to the relations of the deceased; but if on his trial the fact be proved, and not to have been wilful, the bishop is to judge him. There is a manslaughter punishable as murder, by statute; by 1 Jac. I. cap. 8. if any person shall stab another, not having then a weapon drawn, or not being stricken first, so that he dies within six months, although it were not of malice afore-thought, it is felony without benefit of clergy; but this doth not extend to persons stabbing others *se defendendo*, or by misfortune, &c. with no intent to commit manslaughter; and the statute relates to the party only that actually gave the stroke, or stabbed the other, and not to those that were aiding or abetting. Blackst. Com.

MANSLE, in *Geography*, a town of France, in the department of the Charente, and chief place of a canton, in the district of Ruffec; 12 miles N. of Angoulême. The place contains 1230, and the canton 14,536 inhabitants, on a territory of 269½ kilometres, in 25 communes.

MANSO GIAMBATISTA, in *Biography*, marquis of Villa, an eminent patron of polite literature, was born at Naples in 1561. He was brought up to the profession of arms, and, in the early part of life, served in the armies of the duke of Savoy, and in those of the king of Spain. After his return to Naples he devoted his time to literature, of which he was a cultivator and patron. He founded at Naples the academy Degli Oziosi, which held its first assemblies in his house. He was the friend of Tasso, who has inscribed his dialogue on friendship with the name of Manso: he patronized the poet Marino, and honoured the memories of each of them with a biographical eulogy. The great Milton was known to him, and treated by him with much kindness. He praised him very highly in a Latin distich, though at that time only a young man, and in the infancy of his fame. Milton repaid his civilities by addressing to him a Latin

eclogue entitled "Manfus," which is thought to be one of his best performances in that language. The works of Manfo are chiefly of the light and amatory kind. He was the principal promoter of the college of Nobles in Naples, to which, at his death, he left all his property. Moreri.

MANSORA, in *Geography*, a town of Arabia, in the province of Yemen, and government of Hodsjerie; 18 miles E.S.E. of Taës.

MANSORA, or *Manfoura*, a town of Egypt, on the right bank of the eastern branch of the Nile, built as a bulwark against the Christians. The Christians of Syria, settled here, are the chief traders; and the principal articles are the fine rice growing round the lake, and sal ammoniac. Here are also large chicken ovens. A canal is made from the Nile to the lake Manzaleh. Dr. Pocock supposes that Manfura was the ancient Tanis or Zoan of scripture; 24 miles S.S.W. of Damietta. N. lat. 31°. E. long. 31° 36'.

MANSORA, a town of Africa, in the kingdom of Fez, near the sea-coast on the river Guir; 60 miles W. of Mequinez.

MANSORAH, or **MANSURAH**, the same with Bhakor or *Bekker*; which see.

MANSORIUS MUSCULUS, in *Anatomy*, a name given by some writers to that muscle of the face more generally known under the name of the masseter.

MANSOURAH, in *Geography*, a ruined town of Algiers, without walls and inhabitants; 12 miles E. of Boujeiah.—Also, a river called Sifaris, which runs into the sea; 18 miles E. of Boujeiah.

MAN-STEALING, in *Law*. See **KIDNAPPING**.

MANSTEIN, CHRISTOPHER HERMAN DE, in *Biography*, a military commander and writer of memoirs, was born at Petersburg in 1711. He obtained the rank of captain of grenadiers in the Russian service, and, soon after the death of Anne, was commissioned to arrest the regent Biren and his family. For this service he was rewarded with the rank of colonel, and with an estate in Ingria. Of both these he was deprived on the accession of Elizabeth to the throne of Russia, and he then, without hesitation, entered into the Prussian army as a volunteer, obtained considerable promotion, and was killed by a musket-shot in the year 1756. He is known as a writer by "Memoirs of Russia, historical, political, and military, from the Year 1727 to 1744," written in the French language. These were sent by the earl marshal Keith to David Hume, translated into English, and published in 1770. They were afterwards published in French at Lyons in two vols. 8vo. They are reckoned valuable as a fair and authentic narrative of the important events which happened during that period, and they are esteemed as remarkably accurate in their accounts of military transactions.

MANSUM, in *Geography*, a river of Africa, on the Gold Coast, which runs into the Atlantic; five miles W. of Fredericksburg.

MANSURA, a town of the Arabian Irak, seated on the Euphrates; 110 miles W.N.W. of Bassora.

MANSURCOTTA, a town of Hindoostan, in the circle of Cicacole; eight miles S.S.W. of Ganjam.

MANSURIA, an island in the river Nile; 25 miles N. of Syene.—Also, a town of Arabia, in the province of Yemen; eight miles N. of Bel el Fakih.

MANSWORTH, a town of Austria; nine miles S.E. of Vienna.

MANTA, LA, a town of France, in the department

of the Stura, situated between the Maritime and Cottian Alps; with a castle placed on an eminence near the town. The gardens are filled with trees of citrons, oranges, and myrtles, and tender plants not capable of enduring the other parts of Piedmont; two miles S. of Saluzzo.

MANTA Bay, a bay of the Pacific ocean, on the coast of Para, about 20 miles S. of the equator, famous formerly for a pearl fishery, which has been discontinued, and deriving its name from a multitude of large fishes called mantas, in the capture of which the adjacent inhabitants are employed.

MANTALINGA, a town of the island of Sibiu, one of the Philippines, inhabited by natives, exempted from tribute, because they first acknowledged the sovereignty of the Spaniards.

MANTANNARE, a small island in the East Indian sea, near the N.W. coast of the island of Borneo. N. lat. 6° 38'. E. long. 116° 27'.

MANTARO, a river of Jauja, so called from the province it pervades, joins the Maranon at 12° 6', and serves to propel the chief river towards the N.E.; the course having formerly been towards the N.W. See **MARANON**.

MANTECU, a sort of preparation of butter used by the Turks when they travel with their caravans. This is first boiled over the fire, and then salted and kept in vessels made of tough leather, worked round a wooden frame, of the same shape with the vessels in which they bring their balsam from Mecca.

MANTEGAR, or **MAN-TIGER**, as it is sometimes written, in *Zoology*, is the tufted ape, with a nose and head fourteen inches long; the nose of a deep red, face blue, and both naked; black eye-brows; ears like the human; on the top of the head is a long upright tuft of hair; and on the chin another; two long tusks in the upper jaw; fore-feet like hands, and the nails on the fingers flat; the hind-feet have the thumbs less perfect, and the nails imbricated; the fore-part of the body and the inside of the legs and arms naked; the outside covered with mottled brown and olive hair; that on the back dusky; the buttocks red and bare; and the length from the nose to the rump three feet two inches. This animal is very fierce and falacious; will sit on its rump, and support itself by a stick; and in this attitude hold a cup in its hand, and drink out of it; its food is fruit. Pennant. See **SIMIA Mormon**.

MANTEGNA, ANDREA, in *Biography*, born at Padua, or in its district, of low parents, in 1431, became the pupil of Squarcione, who was so deeply struck with his talents that he adopted him for his son. He repented of it when Andrea married a daughter of Jacopo Bellini, his competitor. But the censure, which now took place of the praise he had before lavished on his pupil, only added to his improvement. Certain basso-relievos of the ancient Greek style, possessed by the academy in which Andrea studied, captivated his taste by the correctness of their outline, the simplicity of the forms, the parallelism of the attitudes, and strictness of the drapery: the dry fervility with which he copied these, suffered him not to perceive that he had lost the great prerogative of the originals, the soul that animates them. The sarcasms of Squarcione on his picture of St. Jacopo, made him sensible of the necessity of expression and character: he gave more life to the figures in the story of St. Christophoro; and in the face of St. Marco, in the church of St. Giustina, united the attention of a philosopher with the enthusiasm of a prophet.

The criticisms of Squarcione improved Mantegna in expression, the friendly advice of the Bellini directed his method and fixed his principles of colour. During his short stay at Venice he made himself master of every advantage of that school, and in some of his pictures there are tones and tints in flesh and landscape of a richness and zest equal to the best Venetians of his day. Whether he taught the Bellini perspective is uncertain: Lomazzo affirms, that "Mantegna was the first who opened the eyes of artists in that branch."

The chief abode and the school of Mantegna were at Mantua, where, under the auspices of Marchese Lodovico Gonzaga, he established himself, with his family; but he continued to work in other places, and particularly at Rome, where the chapel which he had painted for Innocent VIII. in the Vatican existed, though injured by age, at the accession of Pius VI. The style of those frescoes proved that he continued steady in his attachment to the antique; but that from a copyist he was become an imitator.

Of his works in oil, Mantua possesses several; but the principal one, the masterpiece of the artist, and the assemblage of his powers, the picture called *La Virgine della Vittoria*, painted for J. F. de Gonzaga, Marchese di Mantua, in honour of a victory he gained over the French upon the banks of the Taro, and afterwards placed in the *Oratorio de Padri di S. Felippo*, is now among the spoils of the Louvre. The Madonna is seated on her throne with the infant standing on her lap, and giving benediction to the kneeling marquis in arms before her. At one side of the throne stands the archangel Michael, holding the mantle of the Madonna; at the other St. George, St. Maurice, John the Baptist, and St. Elizabeth on her knees. The side of the throne is ornamented with figures relative to the fall of Adam: the scene is a leafy bower peopled by birds, and here and there open to a lucid sky.

No known work of Mantegna equals, in design, the style of this picture: they generally shew him dry and emaciated: here he appears in all the beauty of select forms: the two infants and St. Elizabeth are figures of dignity, so is the archangel, who seems to have been, by the conceit of his attitude, and the care bestowed upon him, the painter's favourite object. The head has the beauty and the bloom of youth; the round fleshy neck and the breast, to where it confines with the armour, are treated with great art; the expression is, to a high degree, spirited and characteristic. The countenance of the Madonna is mild and benign; that of Christ, humane. The future prophet is announced in the uplifted arm of John. The guardian angel kindly contemplates the suppliant, who prays with devout simplicity. The whole has an air of life. All the draperies, especially that of St. Elizabeth, are elegantly and correctly folded: with more mass and less interfection of surfaces they would be perfect.

The extreme finish of execution, as it has not here that dryness which disfigures most other works of this master, does not impair the brilliancy of colour. The heads of the Madonna, of the infant, of St. Michael, have a genial bloom of tints. The lights are every where true, the shades alone are sometimes too grey, or too impure. The general scale of the light has more serenity than splendour, more the air of nature than of art, but the reflexes are too often cut off too glaringly from the opaque parts. The whole of the picture has preserved its tone to this day, is little damaged, and in no place retouched.

Of the remainder of Mantegna's works, besides some frescoes of considerable merit, but much injured, in a saloon of the castle of Mantua, and the well known *Triumph*

of Cæsar, in various compartments at Hampton Court, little now remains. His name is more frequent in galleries and collections than his hand: lankness of form, rectilinear folds, yellow landscape, and minute polished pebbles, are less genuine signs of originals, than correctness of design and delicacy of pencil. It is not probable that a man so occupied by large works, and so much engraving, should have had time to finish many cabinet pictures: the series of his plates consists of upwards of fifty pieces, executed by his own hand, and though he was not the inventor of the art, he was certainly the first engraver of his time.

Andrea had great influence in the style of his age, nor was the imitation of his style confined to his own school: Francesco, and another of his sons, finished some of the frescoes which he had begun in the castle, and added the beautiful ceiling, which shews that the science of foreshortening what the Italians call "*del sotto in su*," though Melozio be its reputed author, was carried much farther by Mantegna and his followers. He died in 1505, aged 74. Fufeli's *Pilkington*.

MANTEIGAS, in *Geography*, a town of Portugal, in the province of Beira; 27 miles S.E. of Viseu.

MANTELETS, in *Military Language*, a kind of moveable parapets, made of planks about three inches thick, nailed one over another to the height of almost six feet, generally cased with tin, set upon little wheels, and guided by a long pole; so that in a siege they may be driven before the pioneers, and serve as blinds, to shelter them from the enemy's small shot.

There are also other sorts of mantelets, covered on the top, of which the miners make use to approach the walls of a town or castle. See *Plate VI. Fortification, fig. 9*.

The double mantelets form an angle, and stand square, making two fronts, which cover both the front and flank of the sappers, &c. when at work: these have double planks, with earth rammed in between them; they are five feet high, and three in breadth, sometimes covered with plates of iron.

It appears from Vegetius, that mantelets were in use among the ancients under the name of *vincæ*; but they were built slighter and much larger than our's, being eight or nine feet high, as many broad, and sixteen long; they were defended by a double covering, the one of boards, the other of faggots, with the ribs of osiers; and were cased without with skins, steeped in water, to prevent fire.

MANTERA, in *Geography*, a small island in the Atlantic, near the coast of Africa. N. lat. 10° 45'.

MANTES, a town of France, and principal place of a district, in the department of the Siene and Oise, seated on the Seine, over which is a bridge of thirty-six arches. The place contains 4300, and the canton 13,803 inhabitants, on a territory of 132½ kilometres, in 23 communes. N. lat. 48° 59'. E. long. 1° 48'.

MANTICA, in *Zoology*, the name by which Piso and some other writers have expressed the pouch or bag of skin under the belly of the opossum, into which the young are received in time of danger.

MANTICLUS, in *Mythology*, a name given to Hercules under which title he had a temple without the walls of Messina, in Sicily. This temple was built by Manticlus the chief of a colony of Messenians, about 664 years before Christ: or, as others say, the leader of a colony which settled in the isle of Zacynthus, now Zante. Pausan. in Messen.

MANTICORA, in *Natural History*, a genus of insects of the order Coleoptera, of which there is but a single species. The generic character is, Antennæ filiform, the joints

joints cylindrical; four feelers which are filiform, the thorax is rounded before, and emarginate behind; the head is projecting, and the mandibles are exerted; the shells are united; it has no wings.

Species.

MANILLOSA. Body large and black; head subglobular, impressed on each side; mandible toothed at the inner base; thorax impressed in the middle, and elevated behind; the margin rounded and notched at the tip; shells above, flat, rough, deflected at the edge, with a very sharp lateral ferrate line; legs simple and black. It is described by M. Olivier, in his "Histoire Naturelle des Insectes," as inhabiting the Cape of Good Hope.

MANTINEA, in *Ancient Geography*, a town of Arcadia, E. of the river Ophis, and N. of Pallantium. This town, in the time of Homer, appears to have been considerable. Antinoe, the daughter of Cepheus, is said to have transported the inhabitants of the old city to a more convenient situation than that which it originally occupied to the banks of the river Ophis; and it is fabulously reported that Antinoe was led to the selection of the spot on which the New Mantinea was erected under the guidance of a serpent, whilst others say that the river derived its name from its winding or serpentine course. After the peace of Antalcidas, so called because he was the ambassador employed by the Greeks in negotiating it with the king of Persia, in the year 387 B.C., the Lacedæmonians, under the conduct of their king Agesipolis I., laid siege to Mantinea, as a punishment of its inhabitants for having taken part with the Athenians in the preceding war. Having defended themselves with invincible courage during the summer, the Lacedæmonians availed themselves of the approach of winter by damming up the current of the river, which was thus made to overflow its banks and overwhelm the houses of Mantinea, upon which the inhabitants were constrained to abandon the noble city which they had long occupied, and to retire to their old villages. After the battle of Leuctra, in the year 370 B.C. the Mantineans returned to their city and rebuilt it, deriving assistance in the undertaking from the Thebans: but they afterwards took part with the Lacedæmonians against their coadjutors. A battle was fought near Mantinea by the combining powers, in which, though the Thebans were victorious, they lost their famous general, Epaminondas. Some time after the formation of the Achæan league, Aretas made himself master of Mantinea: but the Achæans were defeated in a subsequent battle by the Lacedæmonians, under the command of Cleomenes, who took several of their cities, and they were reduced to the necessity of seeking the succour of Antigonus, king of Macedon. Thus aided and encouraged, the Achæans obliged Cleomenes to retire with great precipitation to Mantinea. But he was soon constrained to abandon it to the force brought against him by Antigonus, who took possession of it without any great resistance. The Mantineans, in compliment to Antigonus, suppressed the original name of their city, and called it "Antigonia," by which appellation it was distinguished till the time of Adrian, who caused it to resume its ancient name of Mantinea. Pausanias has particularly described this famous city and its magnificent temples. The first was a large edifice, separated into two parts by a high wall; on one side of which was the statue of Æsculapius by Alcamenes, and on the other that of Latona with her children, by the celebrated Praxiteles. Elevated upon a column was a statue of the historian Polybius, who rendered signal service to the Achæans in their wars with the

Roman republic. Another temple was that of Ceres and Proserpine, in which was a sacred fire which was kept continually burning. The temple of Juno was situated near the theatre, and the goddess was seated on a throne of ivory, having on both sides of her Minerva and Hebe, all which were the works of Praxiteles. Near the altar was the tomb of Arcas, son of Calisto and grandson of Lycaon. Another temple which disgraced the city was dedicated to the infamous Antinous, who contributed to the licentious debauchery of Adrian. From the centre of the town five roads passed in different directions to the principal places of Arcadia.

MANTINERA, in *Geography*, a small island in the Mediterranean, near the coast of Naples. N. lat. 39° 55'. E. long. 13° 52'.

MANTIS, in *Natural History*, a genus of insects of the order Hemiptera, of which there are sixty-four species scattered over the globe, but none of them are found in this country: two or three of them are worshipped by the Hottentots, as the ibis and ichneumon were of old by the Egyptians.

The generic character is, Head unsteady; mouth armed with jaws; feelers filiform; antennæ setaceous; thorax linear; wings four, which are membranaceous and convolute, the under ones plaited. The fore-legs are compressed, ferrated beneath, and armed with a single claw, and lateral jointed process; the hind-legs are smooth, and formed for walking. This is thought to be one of the most singular genera in the whole class of insects, and the imagination can hardly conceive shapes more strange than those exhibited by some particular species.

Species.

FILIFORMIS. Body, as its name imports, is filiform, apterous, and brown; the legs are longer than the body, unarmed. The antennæ are black, and it inhabits South America.

FERULA. Body is filiform, apterous, and green; the legs are longer than the body; the hind thighs are spinous at the tip. It inhabits Guadaloupe: it is large, long, and filiform. The antennæ are of a moderate size, green tipped with brown; body smooth glabrous, without wing-cases; thighs angular; the four hind ones spinous.

CALAMUS. Body filiform, apterous, greenish; thighs striate. Antennæ yellowish; head smooth yellowish; body cylindrical; legs yellowish; the thighs are striate, with raised lines. It inhabits Santa Cruz in America.

ROSSIA. Body filiform, apterous, green; thighs toothed; the legs are short and brown, the thighs are toothed beneath. It is found in many parts of Italy.

ANGULATA. This species is apterous; the head and thorax spinous; wing-cases rounded, very short; thighs angular beneath. This is sometimes denominated the "Mantis gigas," and is an inhabitant of Guadaloupe. The body is of a chestnut brown; the head has two spines and numerous raised dots; thorax with two sharp spines on the anterior lobe, and numerous raised dots, the sides ferrate; wing-cases short, rounded, reticulate; thighs very angular, the four hind ones spinous beneath.

GIGAS. Thorax rough and roundish; wing-cases very short; legs spinous: with respect to colour, the thorax is speckled with green; the wing-cases are reticulate, the base and tip green, pale in the middle; wings pale with transverse brown bars. It inhabits Amboina.

CYLINDRICA. Thorax cylindrical; fore-legs united to the fore-part of the thorax; wing-cases grey, the base and beneath rufous; the wings are brown dotted with white.

Its

MANTIS.

Its habitation is not clearly ascertained, but it is not found in Europe.

PHTHISICA. Thorax roundish, muricate; the wing-cafes are very short; the legs are unarmed. It inhabits South America and India.

NECYDALOIDES. In this species the thorax is rough; wing-cafes ovate, angular, very short: the wings are oblong. It is found in many parts of Asia. The wing-cafes have a raised flexuous line down the middle; the wings are brown, and as long as the abdomen.

ATROPHICA. Thorax four-spined; wing-cafes very short, mucronate at the base. It inhabits Java. The head is unarmed; the wing-cafes are ovate, truncate at the tip.

SPINOSA. Head and thorax spinous; wing-cafes very short and acute. It is found in India. The antennæ are as long as the body; the thorax is brown, rough, with a double spine each side on the fore-part; wing-cafes brown; wings brown, convolute, as long as the abdomen; fore-thighs unarmed, the rest spinous.

BISPINOSA. Thorax is rather round, with two spines on the fore-part; wing-cafes very short; wings rose colour. It inhabits America. The colours of this species are very fine; the antennæ are yellowish: the head is green, with a short spine each side on the crown; thorax green, yellowish on the back; wing-cafes green, striate with black; wings large, rosy, the outer margin green; abdomen linear, yellowish, green at the tip; the legs are spinous.

JAMAICENSIS. This, agreeably to its specific name, is found in the island of Jamaica; and it differs from the last only in having no spines on the thorax.

LATERALIS. Linear and black; the wing-cafes are very short, gibbous, and yellowish at the sides; the antennæ longer than the body, black; thorax yellowish at the sides; wing-cafes with a raised tooth in the middle; wings large, black, edged with yellow; the legs are black. It inhabits Brazil.

AURITA. The head and thorax are spinous; and the wing-cafes have a sub-compressed tubercle in the middle. It is found in the East Indies. The antennæ are as long as the body, varied with black and white; head brown, with numerous sharp spines; thorax brown and spinous; wing-cafes concave and very short; the wings are large and dusky, with a broad pale rufous border on the outer edge, spotted with black, and marked with a broad white band.

LINEARIS. Linear, brown; wing-cafes very short, sub-spinous at the base; antennæ as long as the body; wings long and brown; fore-thighs membranaceous. It inhabits the East Indies.

ROSEA. This species is linear and green; front fulvous; wing-cafes very short; and the wings are rosy, with a green rib; antennæ longer than the body, brown, with three or four white rings; thorax smooth, linear, greenish; wing-cafes vaulted with a black thick spine in the middle; the wings are striate, and the legs yellow.

FLABELLICORNIS. Thorax dilated and membranaceous at the tip; fore-thighs terminating in a spine, the rest in a lobe; antennæ pectinate: these are large, very much feathered and setaceous at the tip; the front is projecting, narrower in the middle, notched at the tip; wing-cafes and wings longer than the body, dusky, sub-pellucid and dilated at the anterior margin. It inhabits Tranquebar.

GONGYLODES. This is one of the most remarkable of the Mantis genus: from the thinness of its limbs, and the grotesque form of its body, especially in its dried state, it seems to resemble the conjunction of several fragments of withered stalks; which is the case also of the larvæ of many of the genera, before the wings are formed. The thorax is

uncommonly long and narrow; the head is small and flat, with two filiform antennæ; behind these, two large polished eyes are placed; the rostrum has the shape of an awl, but it is often split towards the extremity into two points; the elytra, which cover two-thirds of the body of the insect, are reticulated, and crossed over one another; the wings which they cover are veined and diaphanous; the four hind-legs have the appearance of being winged, on account of those large membranous lobes which emerge from their joints; the anterior pair are armed with spines at their first articulation, and towards their extremities they are ferrated on one side. It inhabits varicous parts of Africa and Asia.

PAUPERIA. Thorax is linear and spinulous; fore-thigh terminating in a spine, the others are lobate. It is found in Coromandel, and also in some parts of Portugal.

MENDICA. Thorax margined, toothed; wing-cafes varied with white and green; the margin is dotted with white. It inhabits Alexandria. The head is yellowish; front horned; legs yellowish.

TRUNCATA. Thorax dilated each side at the tip, yellowish; the wings are black at the base, and tipped with white. This is a small insect, and inhabits Cayenne. The thorax is linear, rough, membranaceous, and slightly crenate at the tip; abdomen short, flat, dilated; wing-cafes as long as the abdomen, and yellowish, with a brown callous dot in the middle.

STRUMARIA. This is a green insect. The thorax is much dilated in its whole length; wing-cafes and wings are longer than the abdomen; the body is short; and the abdomen yellowish. It is found in South America.

TRICOLOR. The sides of the thorax are expanded, lobate; head horned; fore-legs very broad. It inhabits India. The eyes of this species are very remarkable, terminating in sharp ear-like horns; wing-cafes pale, spotted with white; wings red at the base, brown in the middle, and tipped with white.

CANCELLATA. Thorax dilated at the sides, membranaceous, and flat; the body is of a dull brown colour; the thorax is flat.

SICCIFOLIA. The thorax is denticulate; the thighs are oval and membranaceous. It inhabits India. The insects of this species are usually denominated walking leaves, from their exact resemblance in colour and shape to a dried leaf. They have no wings, or, at most, mere rudiments; the first two pair of thighs are ferrate, the others simple; the body is very much dilated and rounded.

PECTICORNIS. Thorax smooth; crown subulate; antennæ pectinate. It inhabits Jamaica.

OCULATA. Thorax triangular, filiform; eyes oblong, projecting, spinous; the head is of a pale colour; the eyes are large, pointed, and conic; the thorax smooth testaceous, the angles more dusky; wing-cafes shorter than the wings, white diaphanous, striate, and obtuse; legs long, dusky, and unarmed.

SUPERSTITIOSA. Thorax linear, triangular, slightly ferrate on the fore-part; wing-cafes greenish; the rib of the wings is transversely striate. It is a large insect, and is found in Africa. The thorax is rough on the fore-part, smooth behind; the wings are whitish, having a rib with transverse raised brown lines.

UNDATA. Thorax carinate, grey; wings white, with black waves. It inhabits Tranquebar. The antennæ are filiform and pale; the thorax is filiform, triangular, and rough; wings shorter than the abdomen; thighs lobate at the tip, shanks at the base; the abdomen is long and filiform.

IRRORATA. Thorax is smooth subcarinate; wing-cafes green,

green, with scattered ferruginous dots; the wing-cafes are shorter than the wings. It is found in America.

STRIATA. Thorax carinate, and slightly ferrate at the sides; wing-cafes obscure, hyaline, striate with brown, and shorter than the wings; the head is grey; the antennæ are simple; and the body is brown.

ORATORIA, or Camel-cricket, is the chief of the European Mantis genus. It is found in most of the warmer parts of Europe, and is entirely of a beautiful green colour. It is nearly three inches in length, and in its sitting posture is observed to hold up the two fore-legs, slightly bent, as if in the attitude of prayer: hence the common people have conferred upon it the reputation of a sacred animal; and a popular notion has often prevailed, that a child or traveller, having lost his way, would be safely directed by observing the quarter to which the animal pointed, when taken into the hand. It is, however, in its real nature, a very rapacious animal, devouring all smaller insects that fall in its way, for which it lies in wait with anxious assiduity. It is also of a very quarrelsome nature; and when kept with others of its own species, in a state of captivity, will attack its neighbour with the utmost violence, till one or the other is destroyed in the contest. Among the Chinese, this quarrelsome property in the genus Mantis is turned into a similar entertainment with that afforded by fighting cocks and quails to Europeans. To insects of this kind Mr. Barrow is supposed to allude in his "Travels in China." He says, "They (the Chinese) have even extended their inquiries, after fighting animals, into the insect tribe, and have discovered a species of gryllus that will attack each other with such ferocity, as feldom to quit their hold without bringing away, at the same time, a limb of their antagonist. These little creatures are fed and kept apart in bamboo cages; and the custom of making them devour each other is so common, that, during the summer months, scarcely a boy is to be seen without his cage of grasshoppers." The *M. religiosa*, with the thorax subcarinate, is a mere variety of this species.

PRECARIA. Thorax ciliate with small spines; wing-cafes green, with a divided white and brown spot. An inhabitant of Africa. The head and thorax are of a yellowish-green; eyes ferruginous; fore-legs with a ferruginous spot; wing-cafes longer than the body; wings hyaline, spotted with green. This is the supposed idol of the Hottentots, which those superstitious people are reported to hold in the highest veneration; the person on whom the adored insect happens to light, being considered as favoured by the distinction of a celestial visitant, and regarded ever after in the light of a saint.

SANCTA. Thorax slightly ferrate, yellowish-green; wing-cafes green, immaculate; wings hyaline. It is found chiefly in the south of France. The wings are greenish at the tip; fore-shanks with two black spots beneath.

SIMULACRUM. Thorax ciliate; wing-cafes green, with a white spot in the middle. It very much resembles the *M. precaria*, but the thorax is shorter, thicker, and more ciliate. It inhabits America.

MONACHA. Thorax smooth testaceous; wing-cafes and wings green hyaline; the fore-shanks have two testaceous dots on the fore-side. It is found at the Cape of Good Hope.

OBSCURA. Thorax slightly ferrate, dull grey; wing-cafes with a black spot at the base; the wings also have one at the tip. It inhabits Africa. The head is grey, with a black frontal spot; thorax dusky, with a black dorsal line; fore-legs slightly ferrate; the other parts simple.

HYALIANA Thorax ciliate; wing-cafes hyaline, edged

with green; front is two-toothed. It is found in America. With respect to colour, the head is brown; antennæ ferrate; wings hyaline, striate with brown at the tip.

FENESTRATA. Thorax smooth; wings hyaline; exterior margin of the wing-cafes brown. It inhabits Africa. The thorax is linear; exterior margin of the wings is brown at the tip; legs pale; fore-shanks with a few black spots within.

BIDENS. Thorax is rough; wing-cafes green, with black bars; wings brown-black on the disk. It inhabits America. The head is brown; front with two sharp approximate teeth; thorax linear, grey, with a few black raised dots; wing-cafes with two oblique brown bands; legs brown; thighs pale at the base, and tipped with black; shanks of the second pair lobate.

GRIFEA. Thorax smooth; wing-cafes and wings grey, hyaline, spotted with brown. A specimen in the British Museum is middle-sized. Thighs of the fore-legs a little dilated at the upper margin; spinous on the lower; the other legs varied with grey and brown.

MINISTRALIS. Thorax rough, crenate, as long as the head, ferruginous on the fore-part; wing-cafes green; the head is yellowish; antennæ brown; thorax carinate; outer margin of the wing-cafes subferruginous; fore-thighs fulvous; abdomen brown, pale at the tip. Found in New Holland.

UIBANA. Thorax entire; wing-cafes green, with a ferruginous dot and band. It inhabits India.

RUSTICA. Thorax smooth, brown; wing-cafes shorter than the wings, brown hyaline; antennæ hairy. It inhabits the shores of Patagonia; the head is grey-brown, with globular raised stemmata; the legs are yellowish.

NASUTA. Thorax spinous and ciliate; front projecting, spinous, emarginate. It inhabits the Cape of Good Hope. Head flat; front two-toothed on each side, and widely emarginate at the tip; thorax black with a raised tubercle before and behind; wings and wing-cafes grey hyaline, with numerous brown dots at the nerves; the legs are black and annulate.

LOBATA. Thorax three-lobed; front with a bifid horn; eyes conic, pointed. This also is found at the Cape, and is particularly described by Thunberg; the mouth is varied with green and brown; the front is greenish, with a projecting bifid horn between the antennæ; wing-cafes green, with a white base and spot in the middle; wings black, tipped with white; body varied with green and white; margin of the abdomen elevated and lobate.

PULCHRA. Thorax green throughout; the wings are brown hyaline, ferruginous at the base. It inhabits Tranquebar. The antennæ are brown; head and thorax green, a little yellowish at the edge; wing-cafes green, the margin yellow at the base; abdomen above brown, beneath green; legs yellow.

FAUSTA. Linear, ash-coloured, spotted with black. This is an inhabitant of the Cape, and has been described by Thunberg: it is the tutelary deity of the Hottentots.

PERSPICUA. Dusky; wings and wing-cafes hyaline; but the wings have a brown marginal spot and tip. It is a small insect, and is found at Cayenne; the wing-cafes have a small black dot towards the base.

PAGANA. Wings reticulate, white with a lateral ferruginous spot; ends of the legs chelate. It inhabits France and Germany. The thorax is cylindrical, and entirely brown.

MINUTA. In this the thorax is cylindrical and yellowish; wing-cafes hyaline, with a greenish rib. It inhabits South America. The wing-cafes have a small white dot in the middle;

middle; the abdomen is greenish, and yellowish on the back; the legs of a greenish colour.

PUSILLA. Thorax cylindrical, yellowish; wing-cafes and wings hyaline, immaculate. It inhabits Africa.

CAROLINA. Thorax subciliate, carinate; wing-cafes whitish, waved with brown. It inhabits Carolina; wings and their cafes shorter than the body.

LABIATA. This is an inhabitant of India: it is linear, greenish, unarmed; sides of the head green.

MACULATA. Cinereous; thorax winged, subspinous; legs spotted within with black. This is found in the islands of Japan.

CAPENSIS. This also is cinereous; the thorax is unarmed; the head is conic entirely. It inhabits Africa and India.

PARVA. Livid and smooth; wing-cafes and wings hyaline; segments of the abdomen edged with black. It inhabits America.

CINGULATA. Thorax brownish; wing-cafes green, reticulate with black, and marked with four blackish spots; wings blackish, with black lines, the edge yellowish-brown. It inhabits Jamaica. Abdomen annulate with black; it is two-spined at the tip.

GIGANTEA. Brownish; neck, thorax, and thighs serrate. It inhabits Italy.

ANGUSTA. This is of a greenish colour; the tail is forked; the antennæ are filiform, and as long as the body. It inhabits Antigua.

SIBIRICA. This is supposed to be a variety of the *M. pusilla*, and is an inhabitant of Siberia: the body is varied with yellow and brown; wings hyaline with reddish nerves.

BRACHYPTERA. Cinereous; thorax toothed; wings half as long as the body. Is found also in the deserts of Siberia.

PENNICORNIS. The crown of this insect has a conic spine; the antennæ are feathered and linear; the hind thighs terminate in a lobe. It is found in the deserts bordering on the Caspian sea, and very much resembles in shape and colour the *M. gongyloides*.

MANTLE, or **MANTLE-tree**, in *Architecture*, is the lower part of the breast or front of a chimney. It was formerly a piece of timber that lay across the jambs, and supported the breast-work; but by a late act of parliament, chimney-breasts are not to be supported by a wooden mantle-tree, or turning-piece, but by an iron bar, or by a brick or stone arch. See **CHIMNEY**.

MANTLE, *Mantling*, or *Lambrequin*, in *Heraldry*, that appearance of folding of cloth, flourishing, or drapery, that is in any achievement drawn about the coat of arms. This, properly speaking, is an ornament that was anciently fixed to the helmet, like that now worn round the caps of our light dragoons.

It is supposed originally to have been the representation of a mantle, or military habit, worn by ancient cavaliers over their armour, to preserve it from rust; or, as others hold, a short covering only worn over the helmet to defend the head from the weather, which, in after-times, was lengthened, and made to hang from the helmet below the whole shield. Sometimes it hung in a loose, flowing, ragged manner; sometimes it is represented as cut or entire, and hanging back over the neck of a warrior, in which case it is called a "Cappeline." The forms of these ancient mantlings, and the manner in which they usually waved from the helmet of a warrior, are best represented on ancient seals. In length of time, the use and locality of these mantlings seem to have been forgotten; for we find the heralds, through an unaccountable inadvertency, forming them like

cloaks to receive or cover the whole achievement, instead of pursuing their ancient mode of representing them, as being coverings for the head, or ornaments flowing from the helmet of the warrior, and of the colour of his arms. According to such modernized manner of bearing mantlings, those of the sovereigns are supposed to be of gold doubled with ermine; those of the peers, crimson velvet, folded, and ermine inside; and those for knights and gentlemen, crimson velvet doubled with white satin. The prevalence of this mode becoming so general, that all sorts of persons painted mantles of crimson and ermine on their carriages, Mr. Edmondson, in the year 1760, proposed to several of the peers to paint (on their carriages) their arms, placed in mantles of crimson, with their edges thrown back so as to shew their doublings, or linings, which should be of ermine, and containing a number of rows of ermine spots, equal to those of the guards on their coronation robes, expressing their respective degrees, viz. a baron two rows, a viscount two and a half, an earl three, a marquis three and a half, a duke four, &c. This proposal having met with general approbation, was carried into execution, and had the desired effect of shewing the distinction between the several ranks and degrees of our nobility. After which Edmondson formed mantles for the knights companions of the several orders, taken from the mantle and robes which they wear at their installation.

The mantle is always said in blazon to be doubled, that is, lined throughout with one of the furs, as ermine, pean, vary, &c. See **COAT**.

MANTLE of the Knights of the Garter. See **GARTER**.

MANTLE is likewise a term used in *Falconry*. They say the hawk mantles, that is, spreads her wings after her legs.

MANTLE, Lady's, in *Botany*. See **ALCHEMILLA**.

MANTO, or **OLANCHO EL VIEJO**, a town of Mexico, in the province of Honduras. N. lat. 14° 4'. W. long. 86°.

MANTON, **THOMAS**, in *Biography*, a learned English divine, was born in the year 1620. He was educated in grammar-learning at Tiverton-school, and when he was about fifteen years of age was entered at Wadham-college, Oxford. Here he took his degrees, and was ordained deacon by the bishop of Exeter at the age of twenty. He was first settled at Columpton in Devonshire, and afterwards at Stoke Newington, in the vicinity of London, where he was highly esteemed as a preacher and expofitor of the holy scriptures. From Newington he went to St. Paul's Covent Garden, having been presented to that living by his grace the duke of Bedford. In 1653, he was appointed one of the chaplains of the protector Oliver Cromwell: but in 1660 he took an active part with the Presbyterian ministers in general, in bringing about the restoration of king Charles II., for which service he was nominated one of the chaplains to his majesty, and, in consequence of the king's mandamus, created doctor of divinity. He refused to submit to the act of Uniformity, and under the operation of that act he was, in 1662, ejected from his living, after which he held a private meeting in his own house, but was persecuted and imprisoned for exercising the ministerial functions. He was highly esteemed by persons of great consequence in the state, and was consulted by them with respect to all the treaties for the comprehension with the established church. He had great weight among his own brethren, on account of his zeal and activity in their affairs. He died in the year 1677. He was esteemed a man of great learning as a theologian, and was deeply read in ancient and modern history. He is characterized by doctor Bates as a divine of rich fancy, a strong memory, and happy elocution, improved by diligent

study. His sermons make five large folio volumes, one of which contains 190 on the 119th Psalm. The task of reading these sermons to his aunt, when he was but a child, produced a very unhappy effect on the mind of lord Bolingbroke. In a letter to Swift, he writes, "my next shall be as long as one of doctor Manton's sermons, who taught my youth to yawn, and prepared me to be a high churchman, that I might never hear him read, nor read him more."

MANTRA, in *Hindoo Mythology*. The Asiatics, generally speaking, have great faith in charms, talismans, and similar items imposed by craft on ignorance and superstition. Among the Hindoos this feeling is very prevalent. They have mantras, and tantras, and yantras; and as many books in the Sanskrit language are extant on these subjects, their differences and distinctions are doubtless well known to the Brahmans; although, hitherto, those books do not appear to have been sufficiently examined (and it may be well questioned, if they are worth the labour), to be understood by any of our oriental scholars. As far as hath been made known, a mantra generally means a curse, a sort of imprecatory incantation, either ejaculated or written, and composed of a passage from one of the Vedas, containing the name of some tremendous deity. Sometimes it appears rather to assume the form of what we understand of the word talisman; affecting supernatural purposes, such as rendering a person invisible, &c. Both Hindoos and Mahomedans have great faith in the efficacy of propitiatory incantations, more especially the former, and a corresponding dread of those of a malevolent tendency. It is, of course, the triumph of priestcraft to keep alive these impressions, and the sacred and other books of the Hindoos are well calculated for that effect. The malediction of a priest would seriously affect the comfort and quiet of a pious Hindoo. The following passage from the *Ramayana*, a much esteemed epic poem, as is noticed under that article, will serve to exemplify this, as well as the accredited semi-omnipotency of the Brahmans: and, with those who have faith in these doctrines, affords a sufficient reason to fear the effects of such curses. "Even he who cannot be slain by the ponderous arms of Indra, nor by those of Kali, nor by the terrible chakra of Vishnu, shall be destroyed if a Brahman curse him, as if he were consumed by fire." If the reader be desirous of farther information on the above passage, he will find, under the article **INDRA**, mention of his "ponderous arms," the vajra; and of the "terrible chakra" under **VISHNU**. See also **KALI**. A tantra is a sort of hieroglyphic mysteriously sacred to a particular deity. Of these tantras there are a great many, as we are informed by Mr. Paterfon, in his "Essay on the Origin of the Hindoo Religion," in the eighth volume of the *Asiatic Researches*. (See also the *Hindoo Pantheon*, under **Tantra** in the Index.) The term, as well as Yantra, is applied to invocations of a supplicatory tendency, or to defensive incantations; likewise to a philtre, or charm; and to other fooleries similar to our abracadabra and magic squares. These things are, however, not found in the Vedas, nor even in the Puranas, of the Hindoos, but are taught in great detail by the *Agama Sastra*, a compilation of much later date; fabricated, as hath been reasonably supposed, by persons, who in these, as in other matters, established many unjustifiable practices on the foundations of emblems and allegories, which they misunderstood.

MANTSALA, in *Geography*, a town of Sweden, in the province of Tavastland; 37 miles S. E. of Tavasthus.

MANTUA, in *Ancient Geography*, a town of Italy, S. E. of Brixia, and S. of the lake Benacus on the Mincius. Although this town is celebrated for its antiquity, its origin being traced to the Tusci, 600 years B. C., it is still more

distinguished as the place near which Virgil was born. The town was encompassed by a lake, which was formed by the waters of the river.

MANTUA, in *Geography*, was, previously to the arrangements subsequent to the French revolution, a duchy of Italy, bounded on the N. by the Bressan and Veronese, on the E. by the Ferrarese, on the S. by the duchy of Modena, and on the W. by the Cremonese. In length it is about 50 miles, and in breadth 35. It is watered by the Po, which runs through the middle of it, and also by the Oglio, Mincio, Secchia, &c. which discharge themselves into the Po. This territory abounds with corn, fruits, and legumes, and it affords some wine, great quantities of flax, and many good horses. The small duchy of Mantua was taken possession of by Lewis of Gonzaga in the year 1328, and was held by the house of Gonzaga from this period; till at length the last of the family was put under the ban of the empire. In 1703, the emperor transferred to the duke of Savoy that part of the duchy of Montferrat, which had been possessed by the dukes of Mantua as a fief. In 1707, the Imperialists over-ran the whole duchy, and duke Charles IV. died in the following year under the ban of the empire. From this time the house of Austria continued in possession of the duchy, annexed to the government of the Milanese, till by the peace of Luneville it was ceded to the Cisalpine republic, now the kingdom of Italy; and it forms the department of the *Mincio*; which see.

MANTUA, the capital of the late duchy and of the present department of the Mincio, situated on a lake formed by the inundations of the river Mincio; about 20 miles in circumference, and two broad. The two chief bridges leading to this city over the lake are Ponte di Molini, defended by two citadels, and Ponte di St. Giorgio, with fortifications at both ends. The water divides the city into two parts nearly equal, which communicate with each other by six bridges. In summer, when the water stagnates, the insalubrity of the air constrains the higher class of inhabitants to leave the city. The streets are, in general, long, broad, and straight, with handsome stone houses, fine squares, and stately churches. On the other side of the lake are three suburbs. Mantua comprehends four collegiate churches, 21 parochial, 14 other churches and alms-houses, 11 oratories, 40 convents; and without the city are three parish-churches, two other churches, and seven convents. The Jews, of whom there are about 4 or 5000, live in a distinct quarter. The population, exclusive of the garrison, was formerly estimated at 50,000; but it has since been reduced, so that at present it does not amount to more, as some say, than 16,000, or, according to others, 12,000. The position and fortifications render it a place of great strength. In the cathedral, which is a work of Julio Romano, are paintings of the most celebrated masters. The church of Antonio is more famous for relics than any other in the city. The Franciscan church has an elegant inside and a good library. The edifice formerly occupied as the ducal palace is spacious and roomy; but the ducal gallery and museum were pillaged in 1630 by the Imperialists, so that it is now empty and in ruins. The palace church, however, has some valuable relics and other rich furniture, besides two pictures of inestimable value, viz. one of the Baptism of Constantine the Great, and the other of the Martyrdom of St. Antonio. The university was founded in 1625. The silk and other manufactures are now inconsiderable. This city, after enduring a long siege, was taken by the French in February, 1797; 70 miles S. S. W. of Venice. N. lat. 45° 8'. E. long. 10° 44'.

MANTUA *Carpetanorum*, in *Ancient Geography*, the ancient name,

name, as some suppose, of Madrid; but others think that it was situated near it, and that the present name is Villamanta.

MANTUANO, in *Biography*. See **VENUSTI MARCELLO**.

MANTUANUS, the poetical name of *Battista Spagnuolo*, was born at Mantua in 1448; he entered into the order of the Carmelites, and pursued his studies in various cities, and under different masters. He was particularly attached to Latin poetry, but without neglecting his graver studies. He bore several important offices, undertook many journeys, and was finally made general of his order in 1513. He died in 1516, and a marble statue, crowned with laurel, was erected to his memory. The fame of Mantuanus once stood so high that some writers placed him in parallel with Virgil: others carried the matter still farther, and thought the Pagan ought not to be mentioned in comparison with the Christian poet. He is said to have written 55,000 verses. Erasmus thought highly of his talents, but Scaliger ranked him with mere versifiers. His "Poetical Works" were published at Bologna, in folio, in 1502; and at Antwerp they were re-published in 1576, in 4 vols. 8vo.

MANUAH, in *Geography*, a town of Hindoostan, in Guzerat, in the gulf of Cambay; 10 miles S. of Goge.

MANUAL, **MANUALIS**, signifies what is employed, or used by the hand, and whereof a present profit may be made.

Thus, such a thing is said to be in the manual occupation of one, where it is actually used or employed by him.

MANUAL is the name of a service-book used in the church of Rome, containing the rites, directions to the priests, and prayers used in the administration of baptism and other sacraments; the form of blessing holy water, and the whole service used in processions.

MANUAL Exercise, in *Military Language*, is the exercise of the musket, independently of powder and ball. About the year 1757, a new manual exercise was introduced into the British army, very much resembling the modern improved system of Frederic, the father of the great king of Prussia; who was the first that caused the manual exercise to be contracted; and the motions performed close to the body. This exercise has of late been simplified and reduced to a smaller number of motions. The following are the seven movements of the present manual exercise: 1. Order arms; three motions. 2. Fix bayonets; one motion. 3. Shoulder arms; one motion. 4. Present arms; three motions. 5. Shoulder arms; two motions. 6. Charge bayonets; two motions. 7. Shoulder arms; two motions. See **BATTALION**.

About the same time the evolutions, manœuvres, or field movements, which were various in different corps, and very numerous in some, were reduced to one standard, and confined in number to 18. The purposes of these changes were stated in the "Regulations" to be, the reconciliation of celerity with order; to prevent hurry; to insure precision and correctness; to inculcate and enforce the necessity of military dependence, and of mutual support in action; to adopt such motions only as are necessary for combined exertions in corps, rejecting only what is curious on parade; and to make utility, not show, the principal object. See **BATTALION**, *Formation and Order of the BATTALION*.

MANUBALISTA, the ancient name of the *cross-bow*; which see.

MANUBIÆ, among the *Romans*, the spoils of the

enemy, or rather the money made of the booty when sold by the quaestor.

MANUCAPTIO, in *Law*, a writ which lies for a man, who being taken on suspicion of felony, and offering sufficient bail for his appearance, is refused to be admitted thereto by the sheriff, or other having power to let to main-prise.

MANUCMANUC, in *Natural History*, a name given by the people of the Philippine islands to a very beautiful species of parrot, which is found very frequently wild in the woods there. It is of the same bigness with the common parrot, and is variegated with a great many different colours.

MANUCODE, in *Ornithology*. See **PARADISEA Regia**.

MANUCODIATA. See **PARADISEA Apoda**, **MEROPS Flavicans**, and **MUSICAPA Paradisi**.

MANUCODITOTA. See **TODUS Paradiseus**.

MANUDUCTOR, a name given to an ancient officer of the church; who from the middle of the choir, where he was placed, gave the signal for the choirsters to sing, and marked the measure, beat time, and regulated the music. The Greeks called him *mesochoros*, because seated in the middle of the choir; but, in the Latin church, he was called *manuductor*; from *manus*, and *duco*, *I lead*; because he led and guided the choir by the motions and gesture of the hand.

MANUEL, **COMNENUS**, in *Biography*, emperor of Constantinople, was appointed successor to his father, John Comnenus, at his death in 1139, to the prejudice of an elder brother. The soldiery approved of the nomination on account of his military talents and heroism. He is said to have equalled the most renowned champions of chivalry with regard to warlike prowess, but at the same time no one surpassed him in luxury and dissolute indulgence during the intervals of peace. Soon after his accession he marched into Asia with a powerful army, and having recovered several towns in Phrygia, which had been taken by the Turks, he laid siege to their capital Iconium. He was unable to reduce this important place; and after securing the frontiers by garrisons he returned to Constantinople. During his stay in the capital, he married Germana, or Irene, sister-in-law to the German emperor Conrad, but this connection did not prevent him from engaging in a criminal commerce with his own niece Theodora. In the crusade of 1146, led by Conrad, Manuel, jealous of the passage of a number of ferocious bands through his territories, is charged with having used means for their destruction, and it has been affirmed by the Latin historians, that he privately acquainted the Turkish sultan with the designs of the crusaders. Roger, king of Sicily, having made himself master of the isle of Corfu, which was considered as part of the Constantinopolitan empire, and having also plundered Corinth, Thebes, and other towns of Greece, insulted Constantinople itself. Manuel, therefore, assembled a great fleet, with which he recovered Corfu, after which he carried war into the dominions of his enemy, and reduced the greatest part of the provinces of Apulia and Calabria, by means of his lieutenant Michael Palæologus. His success was so great and important, that he even entertained hopes of acquiring Italy and the western empire: with this view he attached to his cause several nobles in Rome itself, and married his niece to one of the family of Frangipani. His expectations were, however, defeated through the jealousies which subsisted between the Roman and Greek churches, and he was obliged to make a treaty and renounce his conquests, retaining only the shadow of a nominal sovereignty.

reignty. Manuel had been engaged, in person, against the Servians, whom he repulsed with great loss, and several of whose towns he took and destroyed. In a progress afterwards through his Asiatic dominions, he was sumptuously entertained by the princes of the West; but an insult which he received from the Turks on his return, induced him to transport a powerful army into Asia, with which he struck such terror into the sultan, that he sued for peace, which was immediately concluded. When Manuel had overcome his foreign and political enemies, he engaged in religious contests, and disturbed the church by endeavours to introduce heterodox opinions. Finding his life drawing to a conclusion he put on the monastic habit, determining to retire from the world. He died in 1177, after a very busy reign of thirty-eight years. He left a son, Alexius, who succeeded him. Univer. Hist. Gibbon.

MANUEL PALÆOLOGUS, emperor of Constantinople, born in 1349, was second son of John Palæologus. His father was not only reduced to a servile dependence on the Turkish sultan, but meanly submitted, at his orders, to deprive his eldest son Andronicus of his sight; he, therefore, associated Manuel to his sceptre, which now ruled over little more than the metropolis and its immediate district. On the death of John in 1391, Manuel was serving by compulsion in the army of Bajazet, but upon receiving intelligence he escaped, and arriving at Constantinople, mounted the throne. Bajazet immediately invested the city, and compelled the new sovereign to purchase a peace on very ignominious conditions, and after carrying on the contest a short time, he resigned the royal power to his nephew, and embarked for Venice. From Venice he made a progress through the principal courts of the West, to engage the sovereigns to contribute their aid for the defence of the bulwark of Christendom against the Mahometan arms. He visited Italy, France, England, and Germany, and was every where received with a respect and commiseration due to his great misfortunes, but he was unable to rouse the princes to any effectual efforts. After an absence of two whole years he returned, in 1402, to the Morea, where he heard of the defeat and capture of Bajazet by Tamerlane, and of the temporary relief of Constantinople. He was now restored to his throne, and his competitor banished to Lesbos. He soon after recovered several of his provinces, which he enjoyed till his death in 1425, at the age of seventy-six. Univer. Hist. Gibbon.

MANUEL, DON JUAN, grandson of king St. Fernando of Castile, is frequently referred to in Spanish history during the reigns of Ferdinand IV. and Alonzo XI. with whom he was sometimes at open war; but having at length effected the marriage of his daughter Costanza with the infante D. Pedro, then heir of Portugal, peace was established between them. He was present at the great battle of Salado, in October 1340, after which, the victory being so complete and tremendous, Spain was never more endangered by the African Moors. He died in 1347. Don Juan Manuel holds a still higher rank in the literary than in the political history of his country: his writings are among the earliest specimens of Castilian prose; they are twelve in number, of which the titles are given in the General Biography, but only one of them, viz. "El Conde Lucanor," has yet been published. This was first printed by Argote de Molina, in 1575, and it was re-printed in 1642. It is a dialogue between the Conde Lucanor and his friend Patronio, in which the latter offers his friend some good advice, and illustrates all his precepts by examples. Gen. Biog.

MANUFACTORY, from *manu-factus*, q. d. *made with*

hands, a place where several artists and workmen are employed in the same kind of work, or make a commodity of the same kind.

MANUFACTURE is popularly used to signify the work itself; and by extension, the like work carried on independently in different parts of the country.

In this sense we say, the *cotton* manufacture, *woollen* manufacture, *silk* manufacture, *velvet* manufacture, *tapestry* manufacture, *muslin* manufacture, &c. manufacture of hats, stockings, &c.

By 23 Geo. II. c. 13. if any person exports any tools or utensils used in the silk, linen, cotton, or woollen manufactures, he forfeits the same, and 200*l.*; and the captain of the ship, having knowledge thereof, 100*l.* And if any captain of a king's ship, or officer of the customs, knowingly suffers such exportation, he forfeits 100*l.* and his employment, and is for ever made incapable of bearing any public office. And every person collecting such tools for exportation, shall on conviction forfeit them, and 200*l.* (See also 14 Geo. III. c. 71.) By 21 Geo. III. c. 37. the above penalties on the captain of the ship and officer of the customs are augmented to 200*l.*; and a person having in his custody, or procuring to be made any such tool, shall forfeit the same, and 200*l.*, and be imprisoned for twelve months. Prosecution on this clause to be within twelve months after the offence committed. By 22 Geo. III. c. 60. any person exporting any such tools, shall forfeit the same, and 500*l.*; and any officer of a ship, conniving at it, shall forfeit 500*l.*, and if it be a king's ship, forfeit also his office, and be incapacitated.

Much was done under the auspices of the magnanimous prince Edward III., for establishing our domestic manufactures, by prohibiting the exportation of English wool, and the importation or wear of foreign cloths or furs, and by encouraging cloth-workers from other countries to settle here.

MANUFACTURE, *Cotton*, one of the leading and most important branches of our national industry and commerce.

The history of its astonishing progress in the last century, the successive improvements in the machinery, which have been made by various inventors, and the extent of the trade, with other curious important facts, are detailed under the article COTTON: it is needless, therefore, to recapitulate these circumstances, and we shall proceed at once to describe this extensive manufacture, as conducted on the most improved system in some of our largest cotton-mills. Many of our readers may have viewed a cotton-mill with wonder, but not with intelligence, nor with leisure to trace the steps by which the wool from the bag ultimately assumes the form of a very fine thread. Bewildered by such a complication of machinery all in motion, very few, we imagine, are able to recollect, with distinctness and intelligence, the essential part of the processes by which the form of the cotton is so wonderfully changed. Such readers will not think a page or two misemployed, in giving a brief account of the different operations the cotton passes through, from the raw cotton or cotton wool, as imported, to the finished thread; and we shall afterwards enlarge upon each subject, and describe the machinery by which these operations are effected in the most expeditious and perfect manner. For the explanation of these, we have appropriated 13 of our plates, which are entitled *Cotton Manufacture*.

Cotton, it is well known, is the produce of a shrub in the warmer climates of the East and West Indies, and even in the more temperate countries which border on the Levant. It comes to us packed in bags, without any further preparation

MANUFACTURE OF COTTON

preparation than being pretty carefully picked out of the pod in which it grows; but still much dirt, husk, and other impurities remain in it. The cotton wool is imported either in bags or in bales: the bags weigh from $1\frac{1}{2}$ cwt. to 5 cwt., and the bales usually weigh $3\frac{3}{4}$ or $3\frac{1}{2}$ cwt. On arriving at the cotton-mill these are unpacked, and the contents examined at the same time it is turned over and beaten with a flick, and the gross impurities picked out with the fingers. This is called *forting*, and the object of the beating is to soften and open the fibre of the cotton, so as to expose every part. The *forting* is performed immediately when the bags of cotton are opened, but it has still to undergo a second examination, called *picking*; the principal object of the first examination, or *forting*, being intended to ascertain the quality of the cotton, and to find what kind of goods it is best adapted for manufacturing, and in this examination the coarsest impurities and yellow damaged parts are picked out.

After *forting* the cotton, it is carried to the *batting machine*, and the coarser sorts of cotton to the *opening machine*, which is known to the workmen by the name of *devil*. In the *batting machine*, the cotton is spread upon a platform of ropes strained very tight, and a number of rods strike very smartly upon it, by which they open the fibres and loosen the knots of cotton preparative to the succeeding operations: at the same time the violence of the *batting* loosens and shakes out all dirt, dust, and cotton seeds, of which the cotton in its raw state contains a great number, and which would be very prejudicial to the operations of the more delicate machines. The cotton, when first packed up in the bags, is compressed very closely, for the convenience of stowage, and this condenses it into a hard matted mass; but the *batting machine*, striking it violently with small sticks, causes the fibres, by their natural elasticity, and the motion occasioned among them, to gradually loosen and disengage themselves, and the cotton, by repeated strokes, recovers all its original volume.

The *opening machine* has the same objects, and produces the same effects, though in a very different manner, as it consists of a rapidly revolving cylinder, on which a great number of iron teeth, or spikes are fixed, which tear and open the cotton against other similar teeth, which are fixed in a stationary half cylinder or hood, enclosing the other. The *batting machine* is used for the finer kind of cotton; and the *opening machine*, which acts in a more rapid though less effective manner, is employed upon the coarser sorts. After *batting* or *opening*, the cotton is again picked, to remove those finer particles of dirt which were before enveloped in the cotton, but are exposed by the operation of the machine. It is performed by women, who remove all extraneous matter, and every particle of yellow or damaged cotton. The perfection of the article to be produced, depends in a great degree on the care with which the *picking* is performed, and this is almost the only process, in the cotton spinning, which cannot be performed by machinery, because it necessarily requires a discretionary power.

The cotton wool being picked clean, is next *mixed*, that is, the contents of different bags are mixed together with a view of obtaining a similarity in the quality of the cotton which is to be spun. In this operation the greatest art of cotton-spinning consists, and it is that department in which experience alone guides the manufacturer. By a judicious mixture of different sorts of cotton, some spinners will produce a very fine and capital yarn, from such cotton as would, if spun alone, or improperly mixed, only produce coarse and low priced goods. The mixture is effected by making a pile or heap, consisting of successive layers, of the different kinds

of cotton which are to be mixed; then by raking away a small quantity at a time from the edges of the heap, striking the rake from the top to the bottom, through all the different layers, the cotton will be very equally mixed. Sometimes the cotton wool is dyed, and different colours are mixed together. It is now spread out, very evenly and regularly, upon a long cloth, which is rolled up and carried to the

Carding machine.—This consists of a number of cylinders, covered with wire teeth or cards, and revolving with considerable velocity in opposite directions, nearly in contact with each other, and covered by a dome also lined with cards. The cotton, being introduced among these, is continually combed, or carded, by the teeth, until almost every individual fibre is separated and drawn straight, and every little knotty and entangled part disengaged. By passing gradually through the machine from one cylinder to another, the cotton is dispersed lightly and evenly among the teeth over the whole surface of the last, or finishing cylinder, from which it is detached by the mechanism in a continued fleece. This is drawn off, and lapped upon a cylinder turned slowly round by the machine, until the fleece has made a great number of turns upon the cylinder: it is then broken off, by dividing it at one part, so that it forms a fleece called a lap, which is the length of the circumference of the cylinder, and consisting of fifteen or twenty thickneffes, by which admirable contrivance very great regularity is obtained in the thickness of the lap, because if any one part of the fleece produced by the machine is thinner or thicker than it ought to be, in consequence of any irregularity in the spreading of the cotton-wool upon the cloth, previous to carding, such irregularity will have no sensible effect upon the ultimate thickness of the lap, because it is composed of thirty or forty strata, and there is no probability that the inequalities of these several strata will fall beneath each other, but every chance that they will be equally dispersed through the whole, and thus correct each other. The lap, when taken off, is laid flat on a cloth, which, with it, is rolled up and conveyed to a second carding-machine, called the *finishing card*, while the first is called the *breaker*. In this second card it undergoes a similar process to the first, but instead of the fleece being received on a cylinder, it is contracted by passing through a funnel, in which the fleece, being hemmed in on both sides, is gradually contracted to a thick roll, which may be continued to any length as long as the machine is supplied with cotton. This roll or band of cotton is drawn off between two rollers, which compress it into a pretty firm, flat ribband, about two inches broad. The rollers deliver it into a tin can, placed to receive it, and in this it is removed to the

Drawing Frame.—This machine consists of several pairs of rollers, between which the cotton is passed, and every successive pair it is drawn through moves, by means of the wheel-work, with a greater velocity than those preceding it, so as to stretch out the band or sliver of cotton, in the same manner as it would be drawn out, if one part of the sliver were held between the finger and thumb of one hand, and another part, at an inch or two distant, being held in the other hand. Then by drawing the two hands asunder to the extent of four inches, it is evident two inches in length of the cotton sliver would be extended or drawn out to four inches. In like manner, the first pair of rollers through which the sliver passes, are pressed together with a sufficient weight to hold the cotton firmly between them. The second pair of rollers are situated at one or two inches distant, and are made by the wheel-work to revolve more swiftly than the first. The difference of velocity, however, is but small, though the consequence is, that the sliver will be lengthened in the same proportion;

MANUFACTURE OF COTTON.

proportion; for the second rollers take up the cotton much faster than the first pair will deliver it out: it must, therefore, be either forcibly pulled through between the first rollers, or it must be stretched a little, by the fibres slipping among each other, or it must break. When the extension is small, the only effect of it is merely to begin to draw the fibres (which are at present lying in every possible direction) into a straight and parallel position, which is most favourable for the subsequent extensions. The drawing frame contains a third, and some of them a fourth pair of rollers, by which the sliver undergoes a second or third draught; but the combined effect of all these drawings is generally to extend the sliver to four times the length it was when first put to the machine. But as this would reduce the sliver to one-fourth of the size, which is not intended in this stage of the process, four ends or slivers are introduced between the rollers together, and being drawn into one, which is four times the length, it will of course be of the same size as any one of the four which is put in. This drawing process is repeated three or four times, and the alteration it makes in the cotton is to equalize the size of the sliver, on the same principle as before described of the breaking card, viz. by repeatedly combining four together, and drawing them into one: it also disposes the fibres longitudinally and in the most perfect state of parallelism. The operation of carding effects this in a certain degree; yet the fibres, though parallel, are not straight, but many of them doubled, as may easily be supposed, from the teeth of the cards catching the fibres sometimes in the middle, which become hooked or fastened upon them.

Though the general arrangement of the fibres of a sliver from the finishing card is longitudinal, yet they are doubled, bent, and interlaced in such a way, as to render the operation we are now speaking of absolutely necessary.

When the cardings have been passed four or five times through the drawing frame, every fibre is stretched out at full length, and disposed in the most even and regular direction, so that each fibre will, when twisted into a thread, take its proper bearing, in consequence of every one being straightened and having the same tension.

The sliver in this state presents a most beautiful appearance, being so extremely regular in its size, and all the fibres drawn so straight, that it bears a fine glossy or silky appearance. It is upon this sliver or ribband of cotton wool that the operation of spinning begins. The general effect of the spinning process is, to draw out this massive sliver, and to twist it as it is drawn out: but this is not to be done by the fingers, pulling out as many fibres of the cotton at once as are necessary for composing a thread of the intended fineness, and continuing this manipulation regularly across the whole end of the ribband, and thus, as it were, nibbling the whole of it away. The fingers must be directed for this purpose by an attentive eye; but in performing this by machinery, the whole ribband must be drawn out together and twisted as it is drawn. This requires great art and very delicate management: it cannot be done at once, that is, the cotton roll cannot be first stretched, or drawn out to the length that is ultimately produced, from the tenth of an inch of the sliver, and then twisted. There is not cohesion enough for this purpose, it would only break off a bit of the sliver, and could make no further use of it; for the fibres of cotton are very little implicated among each other in the sliver, because the operation of carding and drawing has laid them all parallel in the sliver; and though compressed a little, by its contraction in the card from a fleece of twenty inches to a ribband of two, and afterwards com-

pressed between the rollers of the drawing frame, yet they cohere so slightly, that a few fibres may be drawn out, without bringing many others along with them. For these reasons, the whole thickness and breadth of two or three inches are stretched to a very minute quantity, and then a very slight degree of twist is given it, viz. about two or three turns in the inch, so that it shall now compose an extremely soft and spongy cylinder, which cannot be called a thread or cord, because it has scarcely any firmness, and is merely rounder or slenderer than before, being stretched to about four times the former length. This is called *roving*, and the operation is performed in the

Roving Frame.—This machine is constructed in a great variety of forms, but all of them have the same object in view, viz. to draw out the sliver, so as to reduce it from a large band to a coarse and loose thread: but as this extension would render it so extremely tender, that it would scarcely hang together in passing through the succeeding machines, the roving frame, immediately after having drawn and extended it to the intended size by rollers, operating in the same manner as the rollers of the drawing frame, gives it a very slight twist, as before mentioned, and this loose thread, which is called the roving, is the first rudiment of a thread. Although it is extremely tender, and will not carry a weight of two ounces, it is much more cohesive than before, because the twist given to it makes all the longitudinal fibres bind each other together, and compress those which lie athwart; therefore it will require twice the force to pull out a fibre from among the rest, but still not near enough to break it. In drawing a single fibre others are drawn out along with it, and if we take hold of the whole assemblage in two places, about an inch or two asunder, we shall find that we may draw it to near twice its length, without any risk of its separating in any intermediate part, or becoming much smaller in one part than another. It seems to yield equally over all parts.

Our readers will now perceive, that these processes will ensure all that is wanted, and prepare a roving that is uniform, soft, and still very extensible: in short, fit for undergoing the last treatment of spinning, by which it is made a fine and firm yarn.

It is evident that the roving produced by these operations must be exceedingly uniform. The uniformity really produced exceeds all expectation; for even although there be some small inequalities in the carded fleece, yet if these are not matted clots which the card could not equalize, but only consist of a little more thickness of cotton in some places than in others, this inequality will first be diminished by the lapping of the fleece in the breaking card; and when such a part of the sliver comes to the first roller of the drawing frame, it will be rather more stretched by the second than a thin part would be. That this may be done with greater certainty, the weights of the first rollers are made very small, so that the middle part of the sliver can be drawn through, while the outer parts remain fast held.

Such is the state of the roving as prepared by the roving frame. All the preceding processes are to be considered as the preparations: and the operation of spinning is not yet begun. These preparations are the most tedious, and require more attendance and hand-labour than any subsequent part of the process. For the slivers from which the rovings are made are so light and bulky, that a few yards only can be piled up in the cans set to receive them from the carding and drawing: a person must therefore attend and watch each roller of the drawing and roving frames, to join fresh slivers as they are expended. It is also the most important depart-

ment

MANUFACTURE OF COTTON.

ment in the manufacture; for as every inch will meet with precisely the same drawing and same twisting in the subsequent parts of the process, therefore every inequality and fault of the sliver, indeed of the fleece as it quits the finishing card, will continue through the whole manufacture, in a greater or lesser degree, being only diminished, not corrected, by the drawing, doubling, &c. The spinning of cotton-yarn now divides itself into two branches. The first performed by what were called jennies, when worked by the hand, but since they are moved by the power of a mill, they are called mules: the manner of action resembles the ancient spinning with distaff and spindle. The second method, called spinning of *twist*, or *water-spinning*, because it was the first spinning performed by a water-wheel, is in imitation of the spinning with the fly-wheel, or jack and flyer. The two methods differ in the same manner, as the old wool or cotton-wheel differs from the spinning with the flax-wheel. Mr. Arkwright's chief invention, the substitution of the machinery for the immediate work of the human finger, was at first only applied to the manufacture of twist, or water-spinning. We shall, therefore, first direct our attention to this.

The *water-spinning* process is little more than a repetition of that gone through in making the first slivers or rovings, which are formed on bobbins, either by the roving frame, or are afterwards bound on bobbins by the hand. These bobbins are set on the back part of the

Spinning-frame, in which the roving is drawn, and extended to any required degree of fineness; and the proper twist being given to it, forms it to the required thread. The spinning-frame is provided with systems of rollers, in the manner of the drawing-frame, through which the roving passes, and is drawn out according to the size of the thread which is required to be spun, which varies from four to seventeen times; and it is then twisted more or less, as the thread is required to be hard or soft: therefore, the spinning process scarcely differs from the roving, except in the twist that is given it, after the last stretching, in its length. This is much greater than the roving, being intended to give the yarn hardness and firmness, so that it will afterwards break rather than stretch any more. The perfection of the ultimate thread or yarn depends, in a great measure, on the extreme softness of the roving; for it is this only which makes it susceptible of an equable stretching, all the fibres yielding and separating alike: and this property will be greatly influenced by the quantity of twist given by the roving-frame. For these points no very distinct rule can be given: it varies in different mills, and with different species of cotton wool, as may be easily imagined. The immediate mechanism, or manipulation, must be skilfully accommodated to the nature of that friction which the fibres of cotton exert on each other, enabling one of them to pull others along with it. This is greatly aided by the contorted curled form of a cotton fibre, and a considerable degree of elasticity which it possesses. In this respect it greatly resembles woollen fibres, and differs exceedingly from those of flax; and it is for this reason that it is so extremely difficult to spin flax in this way: its fibres become lank, and take any shape by the slightest compression, especially when damp in the slightest degree. But beside this, the surface of a cotton fibre has a harshness or roughness, which greatly augments their mutual friction. This probably is the reason why it is so unfit for tents, and other dressings for wounds, and is refused by the surgeons even in the meanest hospitals. But its harshness and elasticity fit it admirably for the manufacture of yarn. Even the shortness of the fibre is favourable; and the manufacture would be very difficult, if the fibre were thrice as long as it generally is. If it be just so long that, in the

finished thread, a fibre will rather break than come out from among the rest, it is plain that no additional length can make the yarn any stronger, with the same degree of compression by twining. A long fibre will indeed give the same firmness of adherence, with a smaller compression by twining. This would be an advantage in any other yarn; but in cotton, the compression is already as slight as can be allowed: were it less, it would become woolly and rough by the smallest usage; and it is already too much disposed to teaze out. Now, suppose the fibres much longer, some of them may chance to be stretched along the sliver through their whole length. If the sliver is pulled in opposite directions, by pinching it at each end of such long fibre, it is plain that it will not stretch till this fibre be broken up, or drawn out; and that while it is in its extended state, it is acting on the other fibres in a very unequable manner, according to their positions, and renders the whole apt to separate and draw more irregularly. This is one great obstacle to the spinning of flax by similar machinery.

Mule-spinning.—A great proportion of the cotton is spun in the mule instead of the water-frame. The preparation it undergoes for either method is the same; at least the processes are similar, except that the quantities of draft, and some other particulars, may be varied in the preparation of the cotton which is to be thus spun in this machine, which is called a mule, either because it is a kind of machine which might easily be turned by a mule, or more probably because it is a sort of mongrel, partaking of the nature of both drawing and spinning, or uniting the action of both the roller and spindle. It consists of three sets of fluted brass rollers, the flutes of which turn into each other. The first set goes faster than the second, and the second faster than the third; between which, when the sliver of carded cotton enters, it is a little lengthened out between the first and second, and farther still between the second and third; after passing which, it is slightly twisted by the rapid circular motion of the spindle. This has the same effect as the spinning-frame; but the quantity of draft between the rollers, or extension of the sliver, is not, like the water-frame, to the full extent which the thread is intended to be. The remainder of the stretching is performed in this manner: the spindles of the mule, which give the twist to the thread, are fitted in a frame, so that they can be moved backward and forward, in a straight line, to and from the rollers; a certain length of the roving being therefore given out by the rollers, the spindles are removed backward to take it up as fast as it comes, and in this motion they twist it slightly: at the same time, but after a certain quantity of the roving, a yard for instance, has been given out by the rollers, their motion ceases; but the spindle continues to recede from them, another half yard for instance, continuing to twist the thread all the while. By these means, it is evident that the thread will be stretched from a yard to a yard and half in length: by this contrivance, the cotton will bear a greater degree of extension than any other, because it is constantly twisted at the same time that it is extended in length.

The invention of mules forms quite an epoch in the history of the cotton trade. A vast improvement was made, about 35 years ago, by the introduction of the spinning jennies, by which from twenty to forty spindles were turned at a time. The spindles were the same as the mule, and had the same motion; but this machine was not provided with rollers to draw out the cotton, previous to twisting, merely depending upon the stretching, to give it the proper extension requisite to form the roving into a thread. But the combination of the jenny with sir Richard Arkwright's invention of drawing, by rollers, forms a method superior to both, at least

MANUFACTURE OF COTTON.

least for fine goods. The method of stretching gives the means, as we have before mentioned, of very great extension; but if this be carried so far as to draw out the coarse loose roving to a fine thread, there will be great danger of its drawing irregularly, that is, more in one place than another. In the original method by the jenny, the rovings were prepared by the hand-wheel: they were loose, coarse, untwisted threads, partaking somewhat of the nature of cardings, though approaching in some degree to spun twist. They were obliged to be prepared by the hand-wheel, because the cardings, which were prepared by hand-cards, were in detached pieces of a certain length, and regularly tapering towards each end: the joining of these together, in such a manner as to produce an equal and regular roving, required a care and attention which could not be effected by machinery.

The combination of sir R. Arkwright's system of preparation with the jenny produced the mule, which, without the defects of its original, spins in the most expeditious and perfect manner. The advantage of this mode of preparing the threads over that of the jenny is, that the fibres of the cotton are all laid longitudinally, and nearly in as small number as is wanted, before they are begun to be much twisted; by which means, threads of any required fineness are made much stronger than they were from rovings, made upon the spindle of the hand-wheel spun in the jenny, which twisted them too much in the first instance; and in the subsequent extension or stretching, by the removal of the spindle, for rendering them finer, many of the fibres were necessarily broken. On one of these mules 240 threads are often spun at once; and two of them may be managed by one woman, with a child to tie the threads which may occasionally break.

It is needless, as the jenny has become an obsolete machine in the cotton manufacture, to enter into any further details, particularly as the mechanism so nearly resembles the jenny still used in the WOOLLEN manufacture. See that article.

The reader moderately acquainted with mechanics, cannot but perceive that by each of the operations now described, the cotton-wool is prepared, and drawn into a fine strong thread, by repeatedly drawing the sliver till its fibres become straight, then reducing it in the roving frame to a coarse thread, and by a slight twist giving it sufficient strength to bear such an extension as will reduce it to the size intended, and then it is immediately twisted into a hard thread. All these processes are only a substitute for a single pull of the finger and thumb of the spinner, which she accommodates precisely to the peculiar condition of the lock of wool which she touches at the moment: she can follow this through all its irregularities, and, perhaps, no two succeeding plucks are alike. But when we cannot give this momentary attention to every minute portion, we must be careful to introduce the roving in a state of perfect uniformity, and then every inch being treated in the same manner, the final result will be equable, and the yarn will be uniform.

The thread being now finished, either by the water-frame or mule, it is carried to the

Reel, by which it is taken off the bobbins of the spinning frame, or the cops of the mule, and formed into hanks. The hank is a measure in cotton trade, composed of seven *leys*, each of 120 yards in length. The reel or frame round which the thread is wound is one yard and a half in circumference, and at every 80 turns (or *bouts*) which it makes, the 80 turns of the thread are tied together to keep them separate, and this measures out 120 yards, which is called a

ley: but the thread is not cut at the *ley*, it is continued to be wound on the reel, till seven such *leys*, or 840 yards, are reeled: it is then cut and called a hank, which is tied up.

The different sizes of cotton yarn, or thread, are denominated according to the number of these hanks which will weigh a pound. The hank of 840 yards in length is the measure used in all English cotton-mills, and thus affords a very accurate and convenient standard for the size of the cotton. The number is ascertained by weighing each individual hank in a little *weighing instrument*, which shews by an index what number of such hanks will weigh a pound. Each hank being twisted up is suspended on the hook of this instrument, and the number being ascertained, the hank is put on a proper shelf till they are all sorted. Then by a table on purpose it is seen how many hanks of any number will weigh 10 lbs. and this number being counted out from any one shelf, is packed up in the *bundling press*, and tied in papers, marked, and sent away for market. Sometimes, the cotton intended for weaving is warped in the warping-mill before it is sent away from the mill: this saves the weaver an immense deal of trouble.

Some of the twist is wound on quills for the shuttle; and others, again, are formed into hanks, some of which are tightly bound round at certain intervals previous to their being dyed, in order to prevent the parts so tied from taking the colour. This is done that the threads may be disposed to warp in the weaving loom, so as to produce the clouds which are seen in various species of the cotton goods, especially *ginghams*.

Some of the cotton thread is dyed in the hank, and other cotton which is intended for sewing, knitting, &c. or to weave fine goods, is bleached; and because in this process, or in dyeing, some shrinking takes place, it is wound from the hanks upon bobbins again by the *winding machine*, and from these bobbins it is again reeled into hanks, in which it is packed up and sent to market: other cotton thread for sewing, mending, and domestic use, is wound into balls of a figure resembling a cask, and the many interfections of the thread are so managed as to produce a very beautiful appearance.

The denominations of the quality of the different kinds of cotton threads are chiefly divided into *yarn* and *twist*, and this is called *mule twist*, or *water twist*, as it is spun either in the mule or water-frame. That thread which is denominated *water-twist*, is used for weaving calicoes, &c. It is spun hard, that is, with a great deal of twist, so that it forms a strong hard thread. It is manufactured of all numbers, from 10 to 60 hanks *per* pound.

The *mule-twist* is used for weaving muslins and the finest cotton goods. The essential differences between this and the water-twist are, that the mule produces much finer articles than are attempted on the water-frame, at the same time it makes a softer thread. As it requires much less power to work it than the water-frame, the manufacturer spins every thing in the mule which will admit of it; but it will only produce the soft kinds of thread. The mule will spin all numbers, from the lowest to 150 or 170 hanks *per lb.* The trade of Manchester is chiefly mule spinning, whilst the water-twist is mostly spun in the country by water-mills, because the great power it requires is too expensive for steam-engines, at least the water-mills have the advantage, being usually in situations where they have their power at a less expence than those turned by steam-engines.

Stocking yarn is spun softer than twist, and two threads are afterwards doubled together in the doubling machine, and then slightly twisted round each other in the twisting machine.

MANUFACTURE OF COTTON.

chine. Sometimes one of the threads is dyed black, or blue, before the twirling, and then it produces a speckled thread, which is called one-thread white. This yarn is chiefly used in the stocking-frame; it is spun in all numbers, from 10 hanks in the pound up to 60. The threads of stocking yarn are but slightly twisted, so that its composition of two threads is always distinctly visible.

Sewing cotton is made either from twist or cotton yarn doubled, and twisted very hard together by passing it a second time through the spinning frame, so as to form a strong thread, which may be compared to a small rope, as the two threads make one very compact and defined thread.

Mending cotton is the same as sewing, but of less twist: indeed the distinction is trifling.

Knitting cotton is twisted with two or three threads, but not so hard twisted as sewing cotton, though it is harder than mending. This cotton is frequently bleached after it is twisted.

Candlewick cotton is a very loose coarse thread, made from the cheapest and most inferior kind of cotton: being only intended for the wick of candles, no great care is used in the manufacturing. A great deal of candlewick is made from tow which is bleached, and makes an article something like the cotton in appearance, but by no means equal to it in quality. This is known by the cant term of *bump*, and many large mills are employed in spinning it. The cotton candlewick is known by the name of *Turkey*, which is made from Smyrna or other cheap inferior kinds of cotton. It is spun generally about $10\frac{1}{2}$ to 11 hanks *per lb.*, and sent off to market wound up in large balls. Oxford candlewick is made from inferior cotton, about seven hanks to the pound. Wiltshire candlewick is made from waste cotton, about No. 7. These articles are spun without the care requisite for yarn or twist: they are usually spun by mules, and in some mills for coarse goods they do not take the trouble to form them into rovings at all, but spin the candlewick at once from the slivers, as prepared by the drawing-frame.

To pursue the progress of the cotton after being spun into twist, we must remove from the cotton-mill to the cottage of the weaver. Here, the warp being fixed in the loom, or, in the language of the weaver, warped, it is divided to give passage to the weft in the shuttle, either by two, three, or more treadles: or if the pattern or course of changes in the order of raising and depressing the threads of the warp be various, so that the weaver could not manage the requisite number of treadles, it is done by a great number of strings which pass over pulleys above the loom, and are drawn one after another by a little boy, above whose head they are disposed in two rows by the sides and between two looms. These looms are, therefore, called draw-boys. These boys will shortly be set aside for machinery, which is rapidly introducing a substitute. For the formation of sprigs, &c. of various colours, there are often as many shuttles as colours, or a number of little swivel looms, such as they use for the weaving of tapes, introduced occasionally, as many as there are sprigs in the breadth of a piece. Quiltings appear to be two distinct cloths, tied as it were together by ditches, which go through both cloths, and in some cases, as in bed-quilts, there is a shuttle which throws in a quantity of coarsely spun cotton, to serve as a kind of wadding. The counterpanes are woven with two shuttles, one containing a much coarser weft than the other; the coarser of the threads is picked up at intervals with an iron pin, rather hooked at the point, so as to form knobs disposed in a sort of pattern.

When the goods are come from the loom, most sorts of

them, previously to being bleached, are fired or dressed, by being drawn, and that not very quickly, over red-hot cylinders of iron, by which the superfluous nap is burnt off. To see such an operation performed upon so combustible a substance, naturally fills a stranger with the utmost concern and astonishment. They are then washed in a wheel with soap and water, and having been well scoured with an alkaline lixivium, are dipped in the oxygenated muriatic acid, diluted to its proper strength. These preparations are repeated alternately, till the goods have attained the requisite whiteness; and between each dipping they are laid out upon the ground, and exposed to the action of the sun and air. When completely bleached, they are either smoothed upon long tables with smoothing irons, or calendered; that is, stretched and pressed between a course of rollers, by which they acquire a fine gloss. Calicoes are printed exactly in the same way as the kerseymeres in Yorkshire, but the works are usually upon a much larger scale. See PRINTING.

Thicksets, corduroys, velveteens, &c. are cut upon long tables, with a knife of a construction somewhat like the sting of a wasp, terminating in a very sharp point, defended on each side by a sort of sheath. This point is introduced under the upper course of threads which are intended to be cut, and with great ease carried forward the whole length of the table.

The rapid increase of the cotton trade appears to have been owing, in a great measure, to the more liberal introduction of machinery into every part of it, than into any other of our staple manufactures. The utility and policy of employing machines to shorten labour, have been a subject which has exercised the pens of many ingenious writers, while their introduction into almost every branch of manufacture has been attended in the outset with much riot and disorder. They are undoubtedly wonderful productions of human genius, the progressive exertions of which neither can nor ought to be stopped; they enable a manufacturer to produce a better article than can be made by the hand, in consequence of the uniformity and certainty of their operations, and at a much lower price, in consequence of the vast quantities of goods they are capable of performing. They thus support the credit of our manufactures abroad, and enable us under the vast load of taxes, and consequent increase in the price of every necessary of life, to meet our foreign competitors with advantage at market. They can even allow the goods to furnish in their passage a considerable revenue to government. And although they do, undoubtedly, on their first introduction, throw some persons out of employ, by changing the nature and course of business, they almost immediately make up for the inconvenience by astonishingly multiplying the absolute quantity of employment. If they have taken away work from carders and spinners, they have returned it them back tenfold, as winders, warpers, weavers, dressers, dyers, bleachers, printers, &c.

It is this machinery which we have now to explain. An extensive cotton mill contains most interesting specimens of human ingenuity and resource, and shews in a striking manner what may be done, when the talents of a great number of individuals are directed to one common object, and where the most trifling part is of such importance (from the frequent repetition of it which is necessary) as to become worthy the consideration of the manufacturer to devise machinery for accomplishing it in a better or cheaper manner. There is, in the cotton trade, such a spirit of improvement, that they have, as a body, less prejudice in favour of old established customs than perhaps any other class of men: this is doubtless a reason of the great perfection of their art,

MANUFACTURE OF COTTON.

as they have made trials of new ideas, without those years of reflection which men in other trades require before they will venture to embark in any new improvement, though ever so promising and favourable in appearance.

Our readers, who are unacquainted with the subject, will now by this sketch have obtained such a general idea of the cotton manufacture, as will enable them to comprehend the technical terms which are necessary to be used in the subsequent explanation of the machinery, and those references which must sometimes be made from one process to another. A large cotton mill is generally a building of five or six stories high: the two lowest are usually for the spinning frames, if they are for water twist, because of the great weight and vibration caused by these machines. The third and fourth floors contain the carding, drawing, and roving machines. The fifth story is appropriated to the reeling, doubling, twisting, and other operations performed on the finished thread. The sixth, which is usually in the roof, is for the batting machine, or opening machine, and for the cotton pickers, who for a large mill are very numerous. This last is not always so occupied, many manufacturers thinking it better to have out-buildings for these parts of the process, and only to have such parts in the mill as require the aid of the large water-wheel, or steam-engine, which turns the whole mill. If the mule is used for spinning instead of the water frame, then the cards are usually put below, because they are then the heaviest and most powerful machinery.

The first machine we shall describe is the *Batting machine*. *Plate II. Cotton Manufacture, fig. 1*, is an elevation sideways, and *fig. 2* an elevation endways, the frame being in both described by dotted lines, that it may not obscure the mechanism: *figs. 3, 4, and 5*, are detached parts of the machine. The moving power is communicated by the mill to an horizontal axis, on which the fly-wheel, *C*, is fixed, to regulate the motion. On this axis four cranks are formed, as shewn at *i, i, i, i*, making equal or right angles with each other; and connecting rods, *i, b*, being extended from these cranks to the lower ends of the levers *g, g*, which are moveable on the centres *f*, cause them to vibrate alternately when the cranks are turned. There are four of these levers situated on each side of the machine, all the four on each side having one common centre at *f*. Each crank on the main spindle has two connecting rods upon it, to actuate two different levers; but which being situated on opposite sides of the machine, of course receive their motion alternately: at the upper ends, *e, e*, of the levers, which, as the figure shews, are much longer than the lower ends, that is, the centre of motion, *f*, is placed considerably beneath the middle of the levers. At the upper ends, *e, e*, of the levers joints are formed, by which they are connected with rods, *x*: these perform the batting, by striking in the manner we shall describe upon the platform *A*, where the cotton is spread. This platform is formed of a long cord, which is repeatedly passed over two rollers, one of which is shewn at *m*, and the other is at the opposite end of the machine: the cord passing round from one of these to the other twenty or thirty times, and having all the turns made parallel to each other, at about an inch asunder, it forms an horizontal platform for the support of the cotton; but to fill up the interstices between these ropes another stationary set is placed. These are strained between two fixed beams of the frame, as shewn in *fig. 4*, which is a plan (and a section is situated immediately beneath it.) The roller *m, fig. 1*, is kept in continual rotation by a train of toothed wheels, marked *k k k k k l*, which communicate the motion by a pinion on the main axis from one to another,

and lastly to the roller by means of a contrate wheel *l*, in which a pinion acts. By these means the endless rope, which extends from one roller to the other, and forms one-half of the platform for the cotton, is in constant motion, and the cotton which is laid upon it at one end traverses slowly to the other, receiving in its passage the blows of the rods *x*, which strike upon it alternately. Their action is produced in this manner; the levers, *g, g*, are forked at the upper ends, as shewn in *fig. 5*, so as to afford a sufficient length of bearing for a short axis *3, 4*, on which the rod *x* moves. The small dotted circle *3*, in this figure, represents the place where the rod unites with the axis, or rather where a small iron tube proceeds from the axis; and in the end of this the wooden rod, *x*, is inserted, and held fast by means of a screw clamp, or hoop, surrounding the end of the tube, and compressing it upon the rod, one side of the tube being split down to admit of this compression. Upon the same axis as the rod *x* are fixed two small pulleys *1, 2*, to each of which a strap is attached, and, after making a turn round their respective pulleys, these are conducted away to a fixed part of the framing, in the manner shewn in *fig. 1*. These straps are of such a length, as to hang loose during a greater part of the time; but when, by the motion of the top of the levers *g, g, fig. 1*, they come to their tension, they operate upon the pulleys *1* or *2, fig. 5*, and turn them half round with their axis, at the same time turning over the rods *x, x*. This motion is more clearly explained by *fig. 3*, which will, at the first view, be seen to be only a detached section of the parts already described in *fig. 1*. *A* represents one of the vertical levers (*g, fig. 1*), and *F* its centre of motion, upon which it traverses from the position *A*, to that represented by the dotted lines *B*, by the action of the crank rod joined to the lower end of it, as before described; therefore the two positions, *A, B*, are to be considered as the extremes of its movement. *E* represents the pulleys which are fixed on the axis of the batting rod *b*, the two appearing as one in this view. One of the straps of these pulleys is fastened by one end at *n* to a fixed part of the frame, and the other end is made fast to the pulley at *o*. The other strap has one of its ends fastened to the pulley at *k*, while the opposite end is attached at *i* to a lever *i m*, whose centre, *G*, is stationary. The lower end, *m*, of the lever has a strap attached to it, which proceeds to the lever *A*, and is made fast thereto at *l*. The operation of this construction may be thus explained: in the position *B*, the strap, *if*, (answering to *ik* in the other position) hangs slack, as in the figure, while the other strap, *rn*, has come to its tension, and has turned over the batting rod to the position *g*. Now, suppose by the action of the crank rod the lever is moved towards the position *A*, it proceeds for some distance with the rod *g*, remaining horizontal, and merely drawing along endways; but when it is advanced rather more than half way, the straps, *lm* and *ik*, come to their tension: the former pulls the lower end, *m*, of the lever, *mi*, after it, and, of course, the upper end, *i*, at the same time moving in an opposite direction, draws the strap, *ik*, with it, turning the pulley *E*, and the batting rod attached to it, over into the position *b*, and striking on the cotton spread on the platform. This motion is performed almost instantaneously, because, the strap *ik* being drawn in one direction, whilst the centre of the pulley it is fastened to moves in an opposite direction, these motions cause the pulley *E*, and the batting rod which is attached to it, to turn over with a double velocity, to what it would have had if simply actuated by the motion of the lever *A*; so that this rapid motion causes the batting rod to strike with an exceedingly smart stroke upon the cotton laid upon the platform. In

MANUFACTURE OF COTTON.

returning back again to the position B, which the crank causes it to do very shortly after having made the stroke, it proceeds, as before mentioned, to beyond the half way, with the straps hanging slack and having no action; but when it has passed rather more than half way, the strap, *n f*, becomes tight, and turns the pulley over, bringing the batting rod to the position *g*, ready to make another stroke; but in turning it over to this position, the rod does not move with such velocity as to strike a blow upon the cushion *d*, *fig. 1*, which is placed to receive it, because the strap, *f n*, is fixed to a stationary point *n*, instead of having a motion in the opposite direction to the lever, as the other strap *l k*, which caused the stroke upon the cotton. In *fig. 1*, the frame is marked B, and *o, o*, represent the levers *i, C, m, fig. 3*. The lever *g, fig. 1*, which is nearly in a vertical position, appears to have two of the rods *x* proceeding from it in opposite directions. This appearance is occasioned by there being two levers in that position exactly behind each other, though they are moving in opposite directions, therefore one of the rods, *x*, remains upon the cotton at A: the other, which belongs to the lever concealed behind, is represented as just rising from the cushion *d*. *Fig. 2*, is an edge view of the machine, where A represents the strap which communicates motion to the machine by means of two pulleys, called the live and dead pulley, from the circumstance of one pulley being fitted loose, so as to slip round freely upon the axis, whilst the other pulley is fixed fast upon the axis: therefore, when the endless strap is shifted upon the loose or dead pulley, it slips round without communicating any motion to the machine; but when it is shifted on the other pulley, the machine immediately commences its motion. E represents the fly-wheel on the opposite end of the axis, and B, B, B, B, are the four cranks which actuate the levers C, C, C, C: *f* is one of the rollers on which the endless cord or platform, D, is wound, and it extends from this to a similar roller on which a wheel, *g*, is fixed; then returning again to the roller, *f*, and after having made in this manner more than twenty turns round the two rollers, the ends are strained tight and spliced together, so that it appears like *fig. 4*, forming a platform on which the cotton lies, and is regularly carried from *f* to *g* by the motion given to the roller *f* through the cog-wheel *e*, and the other train of wheel-work which communicates with the main axis, as before described. At the sides of the platform two boards are fixed which form a trough, and prevent the cotton getting off sideways. The batting rods strike down through openings or notches *d, d, d, d*, cut in these boards. The dotted lines represent other notches to admit the batting rods on the opposite side of the machine, which, as this figure shews, are not precisely opposite, but the rods on one side strike in the interval between those of the others. The cotton, after passing along with the moving cords through the machine, is thrown off, and falls upon a table *i, fig. 2*, which is covered with an endless canvas cloth, and is strained over two rollers *h, k*, which are kept in constant motion by an endless band passing round the wheels *b* and *g*. By this motion of the cloth the cotton is conveyed away as fast as the batting machine finishes it, and is taken off this table by women, who discharge it into baskets, in which it is conveyed to the picking room.

The opening Machine, or Devil.—This machine comes next to be described, being used for similar purposes as the batting-machine, though it is not to be considered as one of the same series, being used for the coarser sort of cotton in the same stage as the batting engine is used for the finer sorts. *Plate III.* contains drawings of one of these machines, in which *fig. 1*, is a plan, and *fig. 2*, a section. In

either of these A A represents a cylinder, put in rapid motion by an endless band passing round the pulley R. This cylinder has a great number of teeth fixed into its periphery, and the hood or arch, E E E E, contains a set of similar teeth or spikes fixed within it. This casing consists of a number of parallel bars or lags, one of which is shewn in perspective in *fig. 5*: these are supported by an iron semicircle B B, *fig. 3*, also erected on each side of the frame. Each of these circles has a number of pins, P P, projecting from it, and every lag has a notch, or cleft, cut at each end, by which they are hung on these pins, forming a very simple manner of fixing the lags; but they can be easily removed when required, to clear the machine from the flue and impurities which it gets out of the cotton. In front of the cylinder a pair of feeling rollers, *d, d*, are fixed, through which the cotton passes to the machine: these rollers are fluted and placed immediately above each other, as shewn in *fig. 2*; then a heavy weight L, being suspended from the pivots of the upper roller, causes them to press together with a sufficient force to draw cotton in between them, and the flutes or indentations of the two rollers mutually locking into each other, they take the cotton more certainly. The lower roller is turned round by means of a bevelled wheel *l, fig. 1*, fixed on its spindle, which receives its motion from a similar bevelled wheel *k*, fixed on the extreme end of a spindle I, fixed perpendicularly to the axis of the main cylinder, and receiving its motion therefrom by a wheel *b*, which is turned by an endless screw *g*, cut upon the extremity of the spindle of the great cylinder.

The cotton is spread upon an endless revolving cloth, which is strained between two rollers, *a, b*, and is in constant motion, in the direction of the arrow in *fig. 2*. This motion is communicated to the roller, *a*, by means of equal cog-wheels *d, d*, which are connected by an intermediate toothed wheel, as shewn in *fig. 2*; M S is a grating, or frame of brass wire (shewn separate in *fig. 4*.) which is extended beneath the cylinder, and against this the cotton is urged by the action of the teeth of the cylinder, and the dirt, dust, and flue, escape through it. It should be observed, that the frame for the machine is closely boarded up on all sides, to keep in the dust and flue which is separated from the cotton. *Fig. 5*, shews the form of one of the lags, and the manner in which the teeth are disposed in it, so that the teeth in the several rows fall opposite the spaces between the teeth of the others: at *i* is a small slip of sheet iron, which stands up perpendicular to the face of the lag like the spikes, and is supported by a kind of wedge, or prop of wood, as seen in the section of the machine, *fig. 2*. These slips of iron run across the whole length: the teeth on the cylinder are disposed in a similar manner, and are provided with a similar iron plate. Their use is to retain the cotton which is worked in the machine from passing through too quickly, and escaping without being sufficiently worked by the teeth. The cotton is spread evenly upon the cloth *b d*, which being in constant motion towards the cylinder, carries the cotton along upon it, and delivers it between the two rollers *d, d*: these give it regularly to the cylinder, which is rapidly revolving in the direction of the arrow near A: its teeth take the cotton, and carry it round between the cylinder and the hood, working it between them, to open and unravel every knot or tuft of cotton, part of which gets formed by the action of the cylinder into a small ball at every one of the iron plates *i*, and this roll, by the motion of the cylinder, keeps revolving slowly round, so that every part of its circumference is successively subjected to the action of the teeth of the cylinder

MANUFACTURE OF COTTON.

as they pass by them. The plates upon the cylinder act in a similar manner, and when the cotton is thrown out finished at M, upon the floor immediately beneath the feet cloth, it has been opened in every part, so as to completely disentangle it, and the dust, cotton seeds, or any other extraneous matter, drops out through the wire grating, S M, upon the floor.

The opening machines used in some of the most improved mills, are provided with two cylinders revolving against each other, so that they resemble two of these machines put together, by which means the cotton is more completely worked in passing through them. The cylinders have then none of the plates fixed upon them, because they are unnecessary, and the spikes or teeth are arranged in a spiral line round the circumference of each cylinder, so that they do not in their motion fall behind each other, and therefore work and open the cotton more effectually. Another great improvement in this double cylinder machine, is the addition of a flue or trunk, which proceeds horizontally from the opening or mouth M, where the cotton is delivered, for a considerable distance, and in the bottom of this is a revolving cloth, which receives the cotton as it is thrown out, and conveys it away to the end of the room containing the machine. Here it falls out into a basket, in which it is conveyed away to the picking room. The flue or trunk at this point rises up, and leads into a chamber of considerable size, and from this returns by a small trunk to the back of the machine. The operation of this trunk is, that the wind raised by the rapid motion of the cylinders proceeds along this narrow trunk with a considerable velocity, and blowing along over the surface of the cotton, which is traversing slowly along with the endless cloth in the bottom of the trunk, it carries away the flue or small cotton with the stream into the large chamber above-mentioned. Here, in consequence of the large area which the air has to pass through, the current is very slow, and the flue subsides quietly on the floor of it, from which it may be taken up in considerable quantities every week, and is a valuable article for making candlewick, or to mix with inferior cottons for that purpose; whereas, if suffered to fly about in the rooms, as in the machine delineated, it does great injury to the work people, for this flue is taken into the lungs by the respiration, causing asthma, and pulmonary complaints: but in the improved machine, this flue is preserved for useful purposes.

The next machine, in the order of the cotton manufacture, is the *Carding machine*. This is shewn in *Plate IV.*, where *fig. 1.* is a plan, *fig. 2.* a section, *fig. 3.* an elevation, and *fig. 4.* various parts to explain the action of this machine. It will not be amiss first to give a short idea of the nature of the operation to be performed by the machine. The card may be compared to a brush made with wires instead of hairs, stuck through a sheet of leather; the wires not being perpendicular to the plane, but all inclined one way in a certain angle. See *fig. 4.* of this plate, where D, C, are these sheets of leather for a pair of cards, and A, A, or B, B, represent the teeth or card-wires respectively belonging to each. Beneath is a view of one wire, insulated, shewing the two teeth, with their bend in the shank, or what is called knee-bend, by which they are inclined to the leather in the manner before mentioned. Now we may conceive that, cotton being stuck upon the teeth of one of these cards, another may be applied to it, and combed or scraped in such a direction as to strike the cotton inwards upon the teeth, rather than tend to draw it out. The consequence of a repetition of the strokes of the empty card, in this direction upon the full one, is a more equable distribution of the cotton upon the surface of the card-teeth; and in doing this, the fibres are combed and laid straight. Then

if one card be drawn in an opposite direction over the other, it will, in consequence of the inclination of its wires, take the whole of the cotton out of the card, whose inclination is the contrary way. In this mode, the operation was formerly conducted by sheets of cards nailed upon boards, which were worked together by hand. To explain how the carding machine imitates this process, we must return to the figures, in which A A is a large cylinder, turned rapidly round by an endless strap on the pulley R. The surface of the cylinder is covered with cards, the sheets of leather for which are glued or nailed on in stripes or sheets parallel with its axis, and disposed in such a direction, that when it revolves in the direction of the arrow, the teeth upon it go with their points forward, so that if a lock of cotton was held against them, it would be drawn inwards upon the teeth. The cylinder revolves under an arch C C, lined with the same kinds of cards as shewn in *fig. 2*; the teeth disposed to meet those of the cylinder. This arch of cards is supported on two iron arches, fixed on each side of the cylinder. These iron arches or bridges have spikes on them, on which the several pieces, lags, or flats which compose the arch are fastened; exactly the same as described in *Plate III.* of the opening machine.

One of the iron arches is shewn at E E, in *fig. 2*, but is not drawn off its full breadth, because it would have concealed the surface of the cylinder from the sight; but in *fig. 1.* they are seen at C C, and in *fig. 3.* at f f. The card-teeth on the cylinder, and those beneath the arch, do not touch each other, but work as close together that a half crown can be put in the space between them without touching, and they are made very accurately circular, that they may always accurately preserve the same distance between.

B is a second cylinder of cards, the teeth meeting the first, as the figure shews. This cylinder revolves much slower than the first, its motion being taken from a small pinion, *t*, *fig. 1*, on the end of the axis of the great cylinder. This works a wheel, situated on a stud or pin *s*; which has also a pinion fixed to it, working a wheel *z*, fitted on another stud, and this carries a small pulley *v*, which communicates by an endless strap with a pulley, E, fixed on the end of the spindle of the small cylinder. As the whole of this train of wheel-work consists of small wheels turning large ones, it is plain the motion of the cylinder, B, must be very slow. On the opposite end of its axis is a bevelled wheel W, working another upon the end of an axis *h*, which has, at its opposite extremity, a pinion, turning a face or contrate wheel *i*, which is on the axis of the fluted feeding rollers between which the cotton passes, and is delivered to the cylinder. The cotton is, as was before described of the opening machine, spread out upon a feeding cloth D, which traverses constantly round two rollers *k* and *l*, one of which is turned by a pinion from the feeding rollers by means of an intermediate wheel at *k*. A small heavy roller, or cylindrical weight, is put upon the cloth beneath, as shewn at *f*, *fig. 2*, and, by its weight, always keeps the cloth to its proper tension, preserving a flat surface above, for the cotton to be spread out upon, and then advancing with the cloth, it is thrown in between the fluted feeding rollers, which deliver it gradually and equably to the cylinder, which carries it round, and works it against the cards fixed within the arch. In this process it becomes very equably distributed over the teeth in the cylinder, and gets carded in so doing. The cotton continues in this manner hanging sometimes in the teeth of the cylinder, and sometimes in those of the arch, but advancing slowly from one tooth to the next, till it has passed clear through the arch, and then it comes to the small cylinder B, which, as before-mentioned, is revolving slowly, in such a direction that its surface

MANUFACTURE OF COTTON.

surface moves the same way as the cylinder, but much slower, and its teeth meet the teeth of the cylinder. Now, as before stated, it is the property of two cards meeting each other to distribute the cotton between them; therefore, the teeth of the cylinder B, having no cotton upon them, receive a full half of what is upon the teeth of the cylinder A, and as it constantly turns round, and bringing up fresh empty teeth, which in their turn take away the cotton from the great cylinder in a constant stream, and would soon empty it, but that it is supplied again with raw cotton from the feeding roller. The cotton taken up by the cylinder B, proceeds with it beneath, till it comes to the opposite side, and then it is removed by the *taker off*. This is a rod or iron bar *g*, situated parallel to the axis of the cylinder, and cut on the lower edge with fine teeth like a comb. It rises and falls parallel to itself, by being united to two rods, K, which are guided by sliding through small holes made in two standards shewn in *fig. 2*, and the lower ends of these rods are jointed to two cranks *e, e*, *fig. 3*, formed on a spindle, which is turned by a pulley *p*, with an endless strap from a pulley, S, fixed on the main axis, close behind the great pulley R. Now by the motion of these cranks, the rod *g* rises and falls, and at the same time moves a little to and from the surface of the cylinder B: indeed it describes a kind of ellipsis, and being so contrived by the direction of the motion of the cranks (caused by crossing the strap which works them), that it is descending at the time when its edge is nearest to the cylinder, and scrapes downwards against, or rather between the teeth thereof, and in consequence removes the cotton from them the whole length of the cylinder at once: and the motion of the crank is so quick, that by the time this piece of cotton, so detached from the teeth of the great cylinder, has moved round with the cylinder, B, as much as its own breadth, the crank makes another stroke, and, in consequence, the second piece detached from the teeth adheres to the first: the third adheres to the second, and so on. The cotton is thus *stripped* or skinned off the cylinder, B, in a continued and connected fleece. The disposal of this fleece constitutes the only difference between the breaking and finishing card. In the former it is received upon a plain cylinder, about half the size of the great cylinder A, which is turned round with a proper velocity by an endless cord from a pulley on the axis of the cylinder B, a small roller resting lightly upon the top of this cylinder with its own weight, and by its pressure causes the fleece to lap regularly upon the cylinder, which continues to turn until it has made 15 or 20 revolutions. The fleece, being then broken off, forms a small fleece, consisting of 15 or 20 thicknesses, called the lap, which is carried to the finishing card, and treated exactly as the raw cotton was at first. The advantage of this method of treating the cotton has been explained, in a preceding part of this article, to consist in the great equality thus produced in the thickness of the lap, which being fed to the finishing card will produce an equable and regular sliver therefrom, and on this circumstance the perfection of the ultimate thread very intimately depends.

The *finishing card* is that which is represented in *Plate IV*. The fleece or lap produced by the breaking card is spread out upon the feeding cloth D, and thus introduced to the machine, which cards it in exactly the same manner as we have described, and the taker off operates in the same way. But the fleece F, *fig. 1*, instead of going to the lapping cylinder, as we have described, is gathered up into a tin funnel marked *m* in *fig. 1*, and *l* in *fig. 2*: it then passes between a pair of rollers *m n*, which compress and flatten the fleece in its contracted state into a pretty firm and connected sliver or band, and deliver it into a can *n*. These rollers are situated

upon a spindle extending across the frame, and turned round by a pulley upon the end of it, which is connected by an endless band with the pulley E, upon the spindle of the cylinder B. By these means the cotton is reduced from the wool to a fine regular and even sliver, which is conveyed away in the tin can to the drawing frame, which we shall soon describe.

The carding engines in many mills are provided with small cylinders, known among the workmen by the technical term of *urchins*. These are covered with cards, and revolve, so that their teeth act with the teeth of the great cylinder, through proper openings left between the top lags of the arch. These small cylinders are turned round slowly by proper bands and pulleys from the main axis. These urchins are situated in pairs, one of which operates to take the cotton off the great cylinder, in the same manner as described of the cylinder B; but instead of being provided with a taker off, to strip the cotton from its surface, it runs close to the other urchin, of similar dimensions to itself, and turning with a different velocity, and the teeth meeting, so as to take it off the first urchin. This second urchin, having thus become charged with cotton, delivers it again to the great cylinder. The object of this contrivance is to obtain a more perfectly equal distribution of the cotton upon the surface of the cylinder, at the same time the urchins tend, by giving the cotton to the cylinder in a new direction, to work it more, as they prevent the cotton passing so quickly through the machine. The employment of urchins does not seem to afford any very great advantages, and it is not a very general system. When an urchin is applied to the lower part of the cylinder, immediately beneath the feeding roller, it is called a *tunner*: in this case it takes the cotton from the feed rolls, and gives it to the great cylinder as it revolves. The great cylinder of a carding engine, as well as any other part where the flue can escape, should be carefully inclosed by a tin plate, or thin boarding, to prevent its escape into the room, where it does great injury to the work people, producing an irritating and incessant cough, which is exceedingly hurtful, as well as the pernicious effects of such extraneous matter being received into the lungs. Carding engines have been used with two great cylinders, surrounded by a multitude of small urchins, in the same manner as those used for wool. (See *WOOLLEN Manufacture*.) These, having two cylinders, card the cotton sufficiently at one operation, without using a breaking card. The method is not near so perfect, because the equality and regularity of the sliver, produced by doubling the lap of the breaker 15 or 20 times, cannot be so completely attained by any other means, but leaves this equalization to be performed in the drawing frame. The double card, however, answers very well for coarse goods, and saves a great deal of attendance in conveying the lap of the breaking card to the feeding cloth of the finisher. Since the time that the drawing for *Plate IV*. was made, the cotton manufacturers have almost universally adopted what were at that time only partially employed, *viz.* cast iron frames for the carding machines, and iron circles for the cylinders, which are covered with lags of the best seasoned mahogany, or other wood least liable to warp. These circumstances, though they do not alter the parts of the machine, are great improvements of it, as the steadiness of such framing, and the stability of their figure, enables the cylinders to run much closer together, without the danger of the teeth of the cylinder coming in contact at times, as they will sometimes do in wooden frames, and thus destroy the card teeth very soon, as well as produce less perfect work. The same remark applies to all the other cotton machines, and, in point of expence, cast iron is far cheaper than wood when

MANUFACTURE OF COTTON.

when a number of the same part are to be made, so that they can all be cast from the same pattern: in point of stability and duration no comparison can be made; and when the mill is built fire proof, the safety from fire is not a trifling advantage, as it saves the manufacturer the heavy expence of insurance, or, what of course is nearly equal, the risk of losing his property by fire.

The drawing frame comes next to be described. *Plate V.* *fig. 1.* is an elevation of the machine, and *fig. 2.* is a plan of what is called a drawing frame of four heads, which is, in fact, a system composed of four distinct machines of exactly the same construction, but arranged on one frame, in the most convenient position to be used successively. *Fig. 3.* is a front view of one of the heads or separate machines drawn detached; and *fig. 4.* is a section answering to it. In *fig. 1.* A represents a cluster, consisting of four of the cans brought from the carding machine: the four slivers from these are passed through the rollers of the machine, and united into one sliver, which is received in the can C, the machine having drawn it out, and extended it to four times the length of the others; it is therefore the same size as any one of them. The construction of the rollers is explained by *fig. 3.* and also the figure at the left hand end of *fig. 2.* in which *ab* represents a live and dead pulley, upon the spindle of the principal, or front roller, by which it receives its motion from an endless strap. This roller is shewn, in *figs. 2.* and *3.* to be double, that is, it has two lengths or acting rollers upon it, each of which receives two distinct slivers from the cans *ll, ll, fig. 2.* In *fig. 4.* these two lengths of rollers appear like one, being behind each other, and exhibiting the circle marked *a*, the other circle described within this being the neck between the two lengths. This roller has another, marked *b*, placed directly over it, the pivots of which are retained in a vertical notch in the frame, and immediately above the pivots for the lower roller, as is shewn in *fig. 1.*; so that the whole weight of the upper roller rests upon the surface of the lower one, the bearings or notches in which its pivots are received being only to guide, not support it. Another pair of similar rollers, *c, d,* are situated at a small distance from the former, and receive their motion by pinions *e, d, figs. 2* and *3,* which are fixed on the pivots of each respectively, and are connected by an intermediate wheel, *e,* fitted loosely on a stud, in the manner very plainly shewn in *fig. 1,* which also expresses the grooves or notches in the standards; in these the pivots of the rollers are retained sideways upon one another, but, as before mentioned, the upper one rests upon the lower one. A small cross bar, *i, fig. 4,* extends from the pivot, or neck, of one of the upper rollers, *d,* to that of the other one, *b;* and from the centre of this bar an iron rod, with a heavy weight, *f,* at the lower end of it, is suspended by a hook formed at the upper end; so that this weight, as well as the weight of the upper rollers themselves, press the upper rollers, *b, d,* upon the lower ones, *a, c,* and thus the sliver of cotton, *g,* which passes between them, is held very firmly down on the flutes of the lower roller, and cannot slip between them. The wheel *c, figs. 2* and *3,* which is fixed upon the pivot of the first roller, is much smaller in diameter than the wheel, *d,* upon the pivot of the back roller, to which it gives motion by the intermediate wheel *e;* therefore it follows, that the motion of the front rollers, *a, b, fig. 4,* will be as much quicker than the back roller *c, d,* in proportion as the wheel, *d,* is larger than the wheel, *c,* which gives it motion; that is, the number of revolutions they will respectively make in any given space of time (as a minute for instance) will bear that proportion: but the back roller, *c,* (as shewn in *fig. 4.*) is much smaller than the other. The velocity of its circumference will, therefore, be slower than

a, in a still greater proportion than the proportion of the two wheels; and the proportion is such, that the roller, *a, b,* will, or ought to, draw four times the length of cotton through them which the back pair, *c, d,* will permit to pass in the same time. The four slivers, therefore, being introduced from the cans *l, l, l, l, fig. 2,* between the back rollers *c, d, fig. 4,* and pressed with such force upon the flutes of the lower roller *c,* that they cannot slip through them, and the other pair of rollers, *a, b,* holding the slivers in the same manner at another part, the consequence of their different velocities is, that as the front rollers, *a, b, fig. 4,* move so much quicker, they draw the sliver forwards faster than the back rollers will suffer it to come; it must be drawn out, or extended in length, between the two pair of rollers, in proportion to their relative velocities, which, as before-mentioned, is the same as the proportion between the wheels *c, d, figs. 2* and *3,* communicating the motion from one to the other, multiplied by the proportion between the diameter of the two rollers, *a* and *c, fig. 4.* The four slivers, after passing through these in two distinct pairs, are all drawn together through a tin funnel *f, fig. 2,* by means of a pair of rollers, the upper one, *i,* of which merely presses upon the sliver lightly by its own weight, and delivers it into the can *k:* the lowest of this pair of rollers receives its motion from the pinion, *e,* on the end of the spindle of the main, or front rollers, by means of an intermediate wheel, *g,* fitted upon a stud or pin in the frame, and turning a pinion, *b,* fixed on the extremity of the spindle of the lower of the two rollers. These pair of rollers do not draw or extend the cotton, their velocities being accurately adapted to take up the four slivers as fast as they come through the others in two distinct pairs, and by drawing them through the funnel, *f,* to unite the four into one, and the slight pressure of the roller compresses them into a firm and connected sliver, which, though compounded of four, is only the same size as any one of the four put in, because it is drawn out to four times the length, and the effect of the machine has only been to straighten and lay the fibres parallel to each other; for the motion the drawing produces among them, always tends to extend each individual fibre to its full length: and it is necessary to unite several slivers together, or the drawing would reduce the sliver to such a small size, that it would not bear sufficient extension without separating and breaking across. The plan, *fig. 2,* shews the disposition of four distinct heads, or sets of rollers, A, B, C, D, all fixed upon one iron frame, E, the upright of which is shewn in *fig. 1.* D is the first head, or that through which the slivers from the carding engine in the cans, *m, m, m, m,* are first drawn and united into one, which is delivered into the can *n.* In this head six cans, or ends, are shewn entering at once, in two sets of three each, and are all united into one, which will, therefore, if the rollers only draw four times, be rather thicker than those put in; but the number of ends put in, as well as the draught of the rollers, is optional: and as the command of the cotton-spinner, who alters them for different kinds of cotton, or different kinds of yarn to be spun as he finds best, having the means of changing the pinions for others of different sizes. It is plain that the can, *n,* will be filled with the sliver in one-fourth or one-sixth of the time that the four or six cans, *m, m,* will be exhausted; and, therefore, it will furnish four cans, or ends, to the second head, *c,* which are placed at *o,* and drawn into one at *p.* Four of these, when filled, go to *q,* and are drawn into one by the head B, and delivered into *r,* which is taken to *s,* and by the head A, delivered finished into the can *k,* in which it is carried to the roving frame. The several heads, as the figure shews, are reversed,

MANUFACTURE OF COTTON.

reversed, with respect to each other, on the frame, to avoid the necessity of carrying the cans round to the opposite side of the frame in passing from one head to the next. Being thus reversed, that is, the sliver of one moving in a contrary direction to that next it, it requires the straps, which turn the several live and dead pulleys, and which all come from one common axis, on which as many drums are fixed, to be alternately crossed, and put on in the common manner.

The drawing frame in *Plate V.* has now (1812) been drawn some years by a gentleman at Manchester, since which, the cotton manufacturers have very generally adopted a method of using three, and sometimes four pairs of rollers, instead of only two pair in each head: by this means, they draw the cotton at two or three times, and, by extending it only a small quantity at each, it is found to draw much more equably than by taking the whole draught at once. The construction of one of these heads will be readily understood, by examining a figure in the drawing (*Plate IX.*) of the spinning-frame we shall shortly describe, which drawing the writer of this article made from one of the spinning-frames in one of the most complete cotton-mills in the kingdom. The rollers used in this spinning and the drawing-frame are so nearly alike, that one may be very well understood from a description of the other.

The Roving-frame.—The preceding machines having prepared a sliver, of which the fibres are laid parallel, it is necessary to reduce this sliver to a convenient size for spinning into a small thread: but to make a sufficient extension to effect this reduction, it is necessary to give the sliver a slight twist as it is drawn, that it may have sufficient cohesion to undergo the spinning.

The preparation of such rovings as shall be perfectly regular in size, and have an equal quantity of twist in every part, and which shall be exceedingly soft, is a most essential point in cotton-spinning: As it is impossible to correct these imperfections in the spinning, they will be given to the thread. A great number of different constructions of roving-frame have been in repute, at different periods, among cotton-spinners; but it is only lately that by a machine, called the double-speeder, it has been brought to perfection. The old roving-can frame, first introduced by sir R. Arkwright, is represented in *Plate VI.*, which was drawn when that machine was much more extensively used than it is now. The figure immediately beneath the title of this plate is a plan of the roving-can frame, and the figure below is a front elevation: in these, *A* is a horizontal beam supported by standards at each end, and carrying the several heads of rollers, and is therefore called the roller-beam. The machine contains four heads or frames of rollers, each of which receives four ends or slivers from the cans, *D, D.* See also the section in the corner. They enter two together between the back roller *c*, and are drawn out between them and the front rollers, *b, d*, to the proper degree of fineness, but which varies with the quality of the yarn which is to be spun. The sliver, after passing through the rollers, is received into a tin can *C*, through a small funnel, *N*, at the mouth thereof. The can is supported on a pivot at bottom, and is kept in rapid motion by a band, working on a pulley fixed at the bottom of the can. The neck of the funnel, *N*, is guided by a collar, to keep the can steadily upright, as it revolves. The rollers of the machine are the same as those of the drawing-frame: they are turned by endless straps upon the pulleys, *p*, of the front rollers, coming up from similar pulleys on an horizontal spindle extended beneath the machine, through its whole length, and receiving motion by a live and dead pulley, *E, F*, from the mill. The same spindle has pulleys upon it, which, by means of bands,

actuate the pulleys on the bottom of the can. These bands are of course conducted over pulleys, to change their directions, from the vertical pulleys on the spindle of *E, F* to the horizontal pulleys on the bottom of the cans; but these are not shewn in the drawings. Each of the bands drives two cans, passing round the pulleys of both. The cans are made with a door, to open on one side, for taking out the cotton-roving, which falls into them from the rollers; and this door is kept closed by a ring, which fits upon the outside of the can, and keeps the door shut, when pushed down to the largest part of the cone; but when lifted up to the top, as shewn near *N*, the door can be opened, and the contained cotton taken out. *L* is what is called the clearer: it is a piece of wood placed over the top-rollers, and pressing gently upon them; its use is to prevent any part of the cotton *lapping*, that is, adhering to the roller, and being carried round with it, so as to wind it up, instead of drawing it through. The manner of action, in this machine, is easily gathered from the description: the slivers pass two together through the rollers, and are reduced or drawn out therein to the proper degree of fineness; then falling into the funnels, *N*, of the revolving cans, they are, by the rapid motion thereof, twisted round; because the centrifugal force disposes the cotton to lie round the inside of the can in a regular coil, forming as it were a lining of cotton to the whole of the interior surface; and by this means the end of the roving becomes in a measure attached to the can, and is twisted round by its motion, so as to form a coarse loose thread, with a very slight twist, and a very soft and open substance. The cans, when they have been in motion such a length of time as the attendant knows, by experience, they will be full of cotton, the ring is raised up, and the door opened to take out the roving, which is put into a box, and carried to a simple machine, called the winding-block: see the figure at the right hand corner of the plate. In this figure, which is an elevation, the box, containing two piles or coils of the roving, is plainly seen: just above it is a cylinder of considerable size, mounted upon a proper spindle, which is turned round by means of a winch: *k, k*, are two small bobbins, mounted on a wire, and receiving the end of the roving; they rest with their weight upon the surface of the great cylinder, and are by the motion thereof turned rapidly round, so as to wind up the roving very quickly on them. The rovings are conducted through holes in a strip or ruler of wood, which is moved slowly backwards and forwards, to lay the cotton equally on all parts of the length of the bobbin, and make a cylindrical figure to the surface of the cotton wound upon it. It is the necessity for this winding of the cotton upon bobbins by a separate process, which is the greatest objection to the roving-can frame, because the tender roving is damaged by every operation it undergoes, *viz.* removing it from the cans, and winding it upon the bobbins, which must be done preparatory to the spinning. Another objection to the roving-can frame is the uncertainty in the manner of twisting; because, when the cotton applies itself to the interior surface of the can, by the centrifugal force, it occasions a stretching or draught on the roving, tending to lengthen it out before it is sufficiently twisted to make any resistance to the slightest draught. This would occasion no inconvenience, if the degree of draught or extension thus occasioned was constant, and uniformly the same; but this is not the case: for it constantly happens that the roving, by gradually gathering from the circumference toward the centre of the can, in the manner of a spiral, and when it arrives in the centre it coincides with the axis of the can, and of course, as no centrifugal force operates to draw it out in length, it merely twists it round.

MANUFACTURE OF COTTON.

round. In consequence of these irregularities in the action, which are constantly happening, the rovings thus produced are always full of thick and thin places; for when the cotton lies close at the inside of the can, it is considerably stretched by the centrifugal force, and becomes thinner and longer, and with less twist in any given length; but when it happens to fall in the centre of the can, it is of a larger size, and of a more rapid twist: but the quantity of these irregularities is very uncertain, because, even when the end of the roving, where it rests upon the coil of it, which is settled in the bottom of the can, is in the centre of the can, it is to be presumed that no draught will take place; but this is not certain, because the roving may swing out into a belly, and by its vibration will occasion some draught, though not so great as in the first instance. For these reasons, the roving-cans are not found to produce such perfect rovings as many other methods, and they are generally laid aside. Sir R. Arkwright saw these defects at first, and in his earliest machine devised a pair of rollers to be placed in the mouth of the funnel of the can, which were, by very ingenious mechanism, kept in constant motion, with such a velocity as to gather the cotton sliver regularly into the can, as fast as it was delivered by the drawing-rollers. By these means the sliver was held between these rollers, and, from their revolution with the can, received a determinate quantity of twist for every given portion of length. The difficulties of this were very great, to cause the rollers, in the mouth of the can, to take the sliver with the exact velocity required, as fast as the upper rollers delivered it; and even when this was accomplished, the objections we have pointed out would in some measure take place within the can; and after all the operation of winding the rovings upon the bobbins, preparatory for the spinning-frame, by the winding-block, is certain to do them injury, stretching and extending them improperly. The next improvement in roving was the use of *skeleton-cans*: these are light frames of iron, revolving on vertical pivots, in the manner of the cans themselves, in *Plate VI.* Within each of these skeletons or frames a common tin can is placed, and revolves with them, receiving the rovings as we have above described. These cans, when full, are removed to a machine called the stretching-frame, which gives them rather more twist, and extends them still farther in length, at the same time winding them on bobbins, which are called cops or coppins, being bobbins with only one end, the other end being a point, so that the cop in figure resembles a *fir-ball*, or pine-apple. The construction of the stretching-frame is the same, except in its proportions, as the mule: we must, therefore, defer the description of this method of roving till we have explained the mule, when we come to speak of the spinning process. Many mills, where cotton is spun on the most improved and economic system, have adopted a method of roving altogether upon the stretching-frame, producing rovings at once from the slivers of the drawing-frame; and this method is found to succeed very well, and be a great improvement upon the method of employing the roving-can frame. We shall next describe a roving machine, called by the workmen in cotton-mills,

The Double-speeder.—This is a roving-frame, which is extremely perfect in its operation, making better work than any other method: it is an improvement upon some machines made by Sir Richard Arkwright, at a very early period of the cotton manufacture; but the improvements are so essential and ingenious, that the maker or makers of them deserve the whole credit. Who is entitled to the invention of these improvements, we have not been informed; but we have seen machines, made by Samuel Smith of Ramsbottom, near Bury in Lancashire, which were extremely good. The drawings, en-

titled *Plate VII.*, or roving-frame, *Plate I.* also *Plate VIII. Cotton Manufacture*, which we have given of this machine, have, like those preceding it, been made before the improvements were brought to the perfection they have since attained; and though the machine has the same parts, the proportions are such, that a machine, made exactly after them, would not operate so completely as those made by Mr. Smith, to whom we refer cotton manufacturers, who wish to adopt such machines, rather than attempting to make them from the drawings in our plates. They will serve, however, to illustrate the principles and mode of their construction. *Plate I.* is a horizontal plan of the machine; and *Plate VIII.* is an elevation, taken in front of the machine. In this figure, A represents the live and dead pulley, which communicates motion to the whole: it is fixed on a short axis, on the extreme end of which is a pulley, B, which communicates, by an endless strap, with another pulley, D, on an horizontal axis *g*: and this has at the end a bevelled wheel, which turns another on a vertical axis *k*, at the lower end of which a conical drum or barrel, H, is fixed; and beneath this it is formed cylindrical, to receive a strap, which passes round the pulleys, *b, b*, on the lower ends of the several spindles, I, I, I; and then returning to the drum again, the ends are united, and form an endless belt, which runs round the whole, turning them all at once with the same velocity: *l, l*, are small rollers, situated at intervals between every two pair of the spindles; these bend the strap out of the straight line, and thus cause it to press against the pulleys, *b, b*, of the spindles, and apply to a sufficient portion of their surface, to turn them round. This is very plainly shewn in *Plate I.*: each of the spindles, I, I, I, has at its upper end a forked piece of iron, *q, q*, fixed on, which is called the flyer; and one of the forks is made tubular, to receive the roving as fast as it is twisted by the motion of the flyer, and convey it to the bobbin, which is fitted quite loosely on the spindle. The cans from the drawing-frame are, as shewn in *Plate I.*, set behind the machine; and the slivers are drawn through a double pair of drawing-rollers, turned by means of a train of wheel-work from the main spindle, bearing the live and dead pulley, A, *Plate VIII.* The slivers pass singly through the rollers, and are drawn out or extended singly; they then pass forwards, and two are drawn together through another double pair of drawing-rollers, the front pair of which are shewn at *c, c*, in *Plate VIII.*: *a, b*, are the pair of wheels which turn them from the main spindle; *f, f*, the weights; and *e*, the clearer. These rollers deliver the sliver to the flyers, at the top of the spindles, I, I, where it first passes through a collar, or eye-hole, *r*, formed on each of the flyers, exactly in the centre of the spindle, and thence it passes through the tube, *q*, before mentioned, to the bobbin *p*: the two back pair of rollers extend or draw out the sliver twice; then the two front pair, which are shewn in *Plate VIII.*, draw it again, and the spindles twist it once for every inch and a half. The tube of the flyer, running swiftly round the bobbin, lays the roving upon it as fast as the rollers deliver it out. The bobbins, *p, p*, are constructed so as to rise and fall upon the spindles, I, I, that they may lay the roving, coming from the end of the tube *q*, regularly upon the length of the bobbin. This is done by an horizontal bar, or rail of wood, N, which has holes through it, to admit the several spindles I, I, I, and the weight of the bobbin *p, p*, rests upon it; so that when it rises and falls parallel to itself, it takes the bobbins with it, elevating them as at *p*, in *fig. 2.* In this position, the bobbin receives the roving, and winds it on the lower part of them; but as the machine continues to wind, the rail with the bobbins gradually sink down; so that every turn of the roving falls close to, but not upon, the former turn, thus disposing it equally through

MANUFACTURE OF COTTON.

through all the length of the bobbins; and when they have descended to the lowest point, and the bobbins have been filled up to the top, it rises gradually up again. This ascending and descending motion of the rail and bobbins is thus produced: the vertical axis of the conical drum, H, has a bevilled wheel upon it beneath, (not seen in the figure,) which turns another, *s*, fixed on an horizontal spindle; at the other end of which is a pinion, *t*, turning a toothed wheel upon the end of an horizontal axis *v*, which carries a bevilled wheel *w*, turning another, on a vertical axis *y*, which has an endless screw at the upper end, turning a wheel, R, upon a long horizontal axis, which has two pulleys or wheels, M, on it: each of these receive a chain, which chains, at the lower end, support the rail N; and when the chains wind up, they elevate the rail with the bobbins; but when they let down the chains, the rail, N, descends. The reversion of the motion which is necessary to effect this, is done by the wheel, *w*, having another bevilled wheel, exactly similar to it, fixed on the same spindle *v*, and very near to the horizontal wheel worked by it: therefore this wheel, on the spindle *y*, being made to work either in one of these wheels or the other, will, in consequence, turn round one way or the other, elevating or depressing the rail N, and the bobbins accordingly: the lower pivot of the vertical axis, *y*, is supported in a horizontal lever, which is, by the motion of the rail N, when it arrives at the highest point of its movement, moved to bring the wheel to work in the opposite bevilled wheel, on the spindle *v*; and then it turns M in a contrary direction, bringing the rail, N, down again; and when it arrives at the lowest point, the bevilled wheel is again thrown in gear with the wheel *w*, and being thus turned in a contrary direction, it raises the bobbins up again. The connecting parts by which the bevilled wheel is shifted every time it is necessary to reverse the motion, are not shewn in the drawing, but they may easily be imagined: *x, x*, represent the weights which are suspended from the upper front rollers, the same as those used in the drawing frame.

What we have hitherto explained of this machine is the original roving-frame, tried by sir Richard Arkwright on finding the defects of the roving-can frame. The objections to this machine in its original state were, that the bobbins, when they became filled with roving, required so much more force to turn them round, in consequence of their superior weight, than when they were empty and unloaded; that they acted, to stretch or draw out the rovings, in the same manner as the can before mentioned; for the revolution of the flyer *q*, round the bobbin *p*, gives the twist to the roving at the nose or socket, *r*, of the spindle; and if the bobbin was stationary, it is evident the roving would be lapped round it once for every turn of the spindle: but this would require the roving to be delivered out by the drawing-rollers much faster than they are intended to do. The consequence of the bobbin being fixed would be, that the roving must be stretched out to a sufficient length to supply as much length as the motion of the end of the tube of the flyer, *q*, requires. Now suppose, instead of the bobbin being fixed stationary, it is only retained by the friction of resting its lower end upon the rail N, the roving will then only be stretched with as much force as will drag the bobbin round after the flyer, with as much velocity as the difference between the quantity of motion of the end of the flyer, and of the roving, as delivered out by the drawing-roller: this difference will enable the bobbin to take up all the roving as it is made.

Now it is plain, that to drag a heavy bobbin thus about, must require more strain on the roving than for a light bobbin, and in consequence, it is always drawn out smaller towards the time when the bobbin becomes filled. This is particu-

larly hurtful, because the roving, which will afterwards spin to the greatest advantage, is so extremely delicate as not to be able to bear the slightest strain; and if the machine requires it to undergo any strain, it must be twisted harder, and this will render it less fit to undergo the spinning. The manner in which these objections are obviated in the double speeder, is by introducing machinery which will give motion to the bobbin, and turn it round with such a velocity, that it will take up the roving just as fast as it is produced; but it is necessary, in effecting this, that the velocity shall be altered every time the bobbin has a new layer or roving beginning to be lapped upon it, because every time this happens the bobbin increases in its diameter, and must therefore move in such a manner as will cause its acting circumference to keep the same velocity at all times. To describe this see *fig. 1*, where for every bobbin, *p*, a small pulley is shewn resting upon the rail N, the spindle passing through its centre. The bobbin, which rests upon it, has a hole made in the underside of it, and the wheel having a pin entering this hole, so that the wheel, being turned round, compels the bobbin to turn with it. An endless strap, *n*, passes round all these wheels, having binders *o*, or pulleys, which bend the strap, and cause it to act upon a sufficient part of the circumference of the wheels, to take such hold as will carry them round. This endless strap also passes round a cylindrical barrel L, fixed upon the upper end of the conical barrel K, which is of the same dimensions as the barrel H, but inverted, that is, the large end of the barrel, H, is opposite the small end of the barrel K. This being the case, an endless strap, *m*, which is passed round both, will communicate the motion of one to the other, and if the axes of the two cones are parallel, the strap will preserve the same tension, whether it works at one or other end of the two cones, because whatever quantity the strap will be loosed by acting on a small part of one cone, it will at the same time be tightened, or taken up as much, by being upon the larger part of the opposite cone; but it is plain that this alteration of the acting point of the strap will produce a correspondent alteration in the velocity of the motion of the cone K, which is turned round by the strap. Thus, the motion of the cone, H, is equable and uniform in velocity, being actuated by wheel-work from the principal spindle of the machine. Now suppose the strap, *m*, at the top of the cone H, then it acts with a small diameter upon the large diameter of the top of the cone K, which therefore moves much slower than H. Now by shifting the strap lower down upon the cones, the acting diameter of H is increased, while K diminishes till they come to a point, where they will be of equal diameter, and of course have equal velocities; but beneath this point, the diameter of K will be the smallest, and of course its velocity will be greater than H, which actuates it. When the machine is first put to work, and the bobbins are all empty, they must move slowly, because they are required to follow the flyer round, so that they will only take up as much as the rollers produce; for if they were stationary, they would gather up, as before-mentioned, as much as the motion of the end of the flyer, therefore, within certain limits, the slower the bobbin moves, the more it will take up; and if it moved as quick as the end of the flyer, it would take up none at all. For this reason, at first starting the machine, when the bobbins are all empty, the strap, *m*, must be at such a height up the cones, that the bobbins will have their proper velocities to wind up the rovings as fast as they are required, and the bobbins rise or fall, as is requisite, to lap the roving equally upon them; but having thus covered each bobbin with one layer of roving, and beginning to wind another layer upon it, the acting diameter of the bobbin is

MANUFACTURE OF COTTON.

increased, and it must therefore turn so much quicker, (that is, it must make so many more turns in any given space of time,) as will cause the increased acting circumference to wind up no faster than it did when it was smaller. This seems, at first hearing, to be a paradox, that it should be requisite to turn round quicker to wind up no faster upon the increased radius; but it is to be considered that, by the bobbin being moved quicker, it follows and keeps nearer the end of the flyer tube, and therefore winds up less, because the quantity which the bobbin will take up depends on the difference between two motions, that is, the difference between the flyer and that of the bobbin which follows it. This increased velocity of the bobbin is occasioned by the strap, *m*, being, at the time when the bobbin is filled with roving up to the top, or down to the bottom, depressed or shifted down on the cones a small quantity, which occasions, as before-described, a small increase in the velocity of the motion of the cone *K*, and of the bobbins. The depression of the strap is performed by a lever, which takes hold of the strap with a fork, and when urged, leads it up or down upon the conical barrel. This lever is actuated by a snail, upon the axis of which is fixed a ratchet-wheel, turned round by proper clicks, levers, and other connecting mechanism, one tooth every time the bobbins and rail, *N*, begin to ascend and descend, or, in other words, arrive at the extreme limits of their motion. Then the snail acting on the lever depresses the strap a sufficient quantity, to produce the alteration of velocity required.

Thus, as the bobbins increase in diameter by the addition of successive layers of the roving, they adapt their velocities to that increase, and taking it up just as fast as it is produced, and no faster, so that the roving, as it passes from the end of the flyer tube to the bobbin, is never stretched, and never becomes slack. The intelligent mechanic will readily perceive that this is practicable, but at the same time he will be sensible of the accuracy requisite in the adjustment of such a machine to its work, and the difficulty of making this adjustment for different sizes of roving. This, perhaps, is the only bar to its general use, that it requires a skilful mechanic to attend and take charge of it, because every different size of roving, which is made in it, will require a different rate of increase or decrease of motion, by means of the strap *m*, for a large thread causes the diameter of the bobbin to increase more rapidly than a small one, and therefore the quantity of shift which the strap, *m*, makes every time on the two cones *K*, *H*, must be determined by the size of the roving, as is also the height at which the strap shall stand when the machine is first set to work, and the bobbins are all empty. These adjustments are made in the lever snail, and other connecting mechanism, which are omitted in our plates. We have attended for a long time to the action of several double speeders of this kind, made by Mr. Smith, and adjusted by him, which performed their work in the most perfect manner, making a roving so loose and soft, that it would part with the slightest force, but at the same time as regular and even as possible, and the yarn spun from it was greatly superior to any which could be produced from the same material by any other means we have seen. We venture to prognosticate that the general introduction of this machine, when a sufficient number of managers are instructed how to make it work properly, will be a great improvement of a most essential department in cotton-spinning.

The rovings, thus prepared on bobbins, are carried to be spun, either, as before explained, in the water-frame, or mule. We shall describe the former first: it is constructed in two very different forms; and though in both the operating parts are the same, the machinery which actuates them are very different. One is called the water frame, being the original

spinning frame, as first constructed by sir Richard Arkwright, whilst the other is a more modern construction, and is known by the name of the throtle frame. Their comparative advantages we shall speak of after having described them both by the aid of drawings made from the most improved machines of both kinds. See *Plate IX.* which contains a drawing of

A Water spinning frame, taken by the writer of this article from Messrs. Struitts' mill, Belper, Derbyshire, whose works are the most complete for the water-spinning trade of any in the country. *Fig. 1.* is an elevation in front of the whole frame; *fig. 2.* an elevation endways, and *fig. 3.* is a plan: the remaining figures are the parts on an enlarged scale. In all the three first figures, the same parts are designated by the same letters of reference: *A* is a bevelled wheel, fixed upon the horizontal axis, which extends through the whole length of the mill. This turns a smaller bevelled wheel upon a vertical axis *B*, which has a drum, *C*, at the lower end, and by a strap, *a*, actuates the whole machine. Another strap, *b*, goes the other way, and works another frame on the opposite side, the drum, *C*, being common to both. The spindle, *B*, passes through the drum, *C*, with a circular fitting, so that it slips freely round within it, without giving motion to the drum, except when it is cast into gear. This is done by two locking bolts, shewn by dotted lines passing through the drum, and both fixed into a collar or socket-piece *d*, fitted to slide up and down the spindle. It has a groove formed round it, in which a fork, at the end of a lever *e*, is received, so that the fork embraces the piece, *d*, in the groove, and when lifted up, raises the two locking bolts with it. This lever is raised by the power of a second lever *D E*, the extremity, *E*, of which, being depressed, raises up the lever *e*, and unlocks the drum from the spindle *B*, by withdrawing the locking bolts from their contact with an arm, *f*, of a wheel, *g*, which is fixed fast on the spindle beneath the drum, and therefore turns with it; but the locking bolts being let down, that their ends may project through the drum, and intercept the cross arm, *f*, of the wheel, the drum and all the machinery are put in motion.

The endless strap, *a a*, passes, as shewn in the figure, the whole length of the frame, makes a turn round the pulley *m*, and comes back again. Other pulleys, *1, 2, 3*, of the same dimensions as *b*, are situated, at intervals, in a direct line between the drum *c*, and the pulley, *m*, to bear the strap, and in the intermediate spaces between these pulleys, the vertical spindles marked *n* are placed in pairs, exactly opposite each other. On the lower end of these, small wheels, *x*, called binders, are fixed, and the strap, *a a*, pressing against them, as shewn by the figure, turns them round, the object of the pulleys *1, 2, 3* being to bend the strap out of the straight line sufficiently, to make it apply to the surfaces of the several binders and turn them round. The last pulley, *m*, is fitted in a frame, and can, by a screw *4*, be moved to strain the strap tight. Above each binder, and on the same spindle, a wheel, *h*, is fixed: it receives two belts *i, k*, (*fig. 3.*) which turn four of the spindles *l, l, l, l*, each belt giving motion to two spindles. The binders *x*, (see *fig. 5.*) are fitted to slip round on their spindles *n*, but can, at any time, be united thereto, to give them motion by a locking bayonet *9*, which is cast in or out of action, at pleasure, by a small lever *10*, in exactly the same manner as the locking of the principal drum: therefore, by the lever *10*, any four spindles can be detached from the machine at pleasure. The spindles, *n*, of the binders have each at the upper end a pinion, which turns a face or contrate wheel *p*, fixed upon the spindle of the front rollers which give out the cotton to the spindles. These rollers are arranged in distinct heads or frames, containing four lengths in each, which supply four spindles.

The

MANUFACTURE OF COTTON.

The construction of one of the heads is shewn in *figs. 4, 5, and 6*; *fig. 4.* being a section of the rollers and spindle; *fig. 5.* a front view of the rollers; and *fig. 6.* an end view. In these, *p* still denotes the face wheel, and *4* the lower front roller. Upon this, which is fluted in the acting parts, the upper rollers *5*, made in two separate lengths, rest, and are pressed down upon the lower one by two heavy weights, *6, 6*, which are suspended, by means of hooks, *7*, from the necks or small parts of the upper rollers, and thus keep them firmly down upon the flutes of the front roller *4*. On the opposite end of the front roller to the wheel *p*, a pinion, *r*, of eleven teeth is fixed: this turns a wheel, *s*, of 28 teeth, which is mounted on a stud or pin, and has a pinion, *t*, of 16 teeth fixed to it, which works a wheel, *u*, of 32 teeth, fixed on the end of the middle roller, shewn in the section, (*fig. 4.*) at *12*, whose motion will be to the front roller nearly as five to one. On the other end of the roller is a pinion of 10, which turns another of 15, on the back roller, *13*, by means of an intermediate wheel, so that this turns only once for one and a half turns of the middle roller; consequently, the roving *14*, (*fig. 4.*) which is introduced between the back rollers, from the bobbins or cops set up in a frame *F*, (*figs. 1 and 2.*) above the machine, is, in passing between the back and middle rollers *12* and *13*, drawn out one and a half times; then between the middle and back rollers *12* and *14*, it is extended five times more, making a draught or extension of $7\frac{1}{2}$ times in the whole; and as fast as the rovings come through the front rollers, they are twisted into a thread by the rapid circular motion of the spindles. But these we have to explain; they are straight steel arbors, *l, l*, (*fig. 4.*) on the lower end of which the whirls or pullies, which receives the band, *i*, for them, are fixed: these spindles are mounted in a frame common to them all, which consists of two rails *14, 14*; the lower one supporting the points or toes of the spindles, and the other having bearings for the cylindrical parts of each spindle, and a strip of wood is screwed against this to keep them up to their bearings. Above this bearing the spindle is only a straight cylindrical wire, and on the upper end of it the flyer, *15*, is fastened, either by screwing it on, or it is stuck fast on by friction, which is sufficient to carry it about. The two arms or branches of the flyer are sufficiently distant for them to revolve round clear about the bobbin *16*, which is fitted loosely upon the cylindrical spindle, and with liberty to slide freely up and down upon it. The weight of the bobbin is supported by resting on a piece of wood *17*, attached by screwing to a rail *M*, which has a slow rising and falling motion, equal in extent to the length of the bobbin between its shoulders, by which means the thread, as it comes through the eye formed at the ends of either of the branches *15*, of the flyer, and is wound by the motion thereof upon the bobbin, becomes equally distributed throughout, its length giving it a cylindrical figure, instead of heaping all the thread at one part, like a barrel, as would happen if the bobbin did not rise and fall. This motion of the bobbin is produced by a bent lever, *16*, (*figs. 1. and 2.*) suspending the rail *M*, with all the bobbins upon it, from the arm *16*; the lower end of the other arm, *17*, bears against, and is moved by a heart or eccentric wheel *18*, nearly of the figure of a heart, which is fixed on an horizontal axis extending the whole length of the machine, and at the other end it bears a similar heart *18*, (*fig. 1.*) fixed on it, which operating upon another lever *16*, suspending the other end of the rail *M*, thus causing it, when the hearts are turned round, to rise and fall equally at each end, or parallel, and move all the bobbins resting upon it together. The motion is given to the spindle of the heart

18, by a small contrate wheel on the end of it, which is turned by a pinion on the lower end of the vertical spindle *19*, receiving its motion by a pair of bevelled wheels from an horizontal spindle *20*, in the middle of which is a cog-wheel *21*, turned by a spiral piece of iron *22*, which is fixed on the main spindle *B*, just beneath the great bevelled wheel. It operates in the same manner as an endless screw, turning the wheel, *21*, round one tooth for every revolution of the main spindle, and this slow motion is communicated by the spindle *19*, and wheel-work just described, to the hearts, which revolve with such a velocity, as will cause the bobbins to ascend and descend so fast, that they lie every turn of the thread close by the side of that preceding it, but not upon it, so that the figure of the bobbin, when filled with thread, will be nearly cylindrical.

The bobbins of the roving frame are put upon a wire, or temporary spindle, and in this state are set up in the frame, *F*, in two rows, one above another, so that they will all turn freely round when the rovings are drawn off from them. These rovings are conducted over wires, as shewn in *fig. 2*, to lead them in the right direction, and are brought, two together, through wire staples fixed in the board *G* (*fig. 4.*), then through notches made in the edge of a piece of iron plate fixed on the edge of the board, and projecting up above the surface of it, and after passing through these notches the rovings enter the back roller *13*, in *fig. 4.* The board, *G*, has a short traversing motion backwards and forwards, by which means it causes the roving to travel backwards and forwards between the rollers, or it would soon, if constantly conducted through the same part of the rollers, wear out the flutes at that part, making a smooth ring round it: but by this traversing motion the wear is equally distributed over the whole length of the fluted rollers, and does not act partially at any one part. The motion is caused, as shewn in *fig. 4*, where *18* is the spindle of the hearts *18* (*fig. 2.*), situated immediately beneath the board *G*: it has a cog-wheel of 18 teeth fixed upon it, turning another, *H*, of 36 teeth, on the axis of which a small crank, *K*, is formed, and by means of a connecting rod draws the board, *G*, backwards and forwards every time it makes a revolution, by means of the cog-wheels, which will be once for every two turns of the hearts. The rovings, two together, as before stated, enter between the back rollers, and then pass forwards to the middle pair, receiving in the passage a draught or extension of one and a half; then advancing through the middle rollers to the front, they are, by the motion thereof, drawn out five times, and in this state delivered to the spindle *L*, which twists the fibres round each other the instant their ends come out, before the rollers leave the other ends, or they would fall to pieces, being drawn out so fine, that the cohesion of the fibres is insufficient to bear any thing, and the twine given to the roving is entirely lost, for it was at first only one turn in $1\frac{1}{2}$ inch in length; and this $1\frac{1}{2}$ inch, being by the draught of the roller drawn out to more than 13 inches, the twist of one turn in this length is imperceptible, and adds no strength whatever to the roving, so that it is necessary the spindle should, by the connection of the thread *41*, passing down from the rollers to its flyer, give a twist to the fibres the instant they come through the roller, so that by twisting one end of each fibre round the other, whilst the opposite ends are held fast between the rollers, they will become a thread sufficiently cohesive to advance towards the spindle, and receive its full quantum of twist to become a hard and strong thread: it passes through a wire eye or staple fixed in a board at *34*, which changes its

MANUFACTURE OF COTTON.

direction into a line with the spindle, to which it is connected by passing through the eye formed at the end of either of the branches of the flyer, which revolves with the greatest rapidity along with the spindle, and thus give twist to the thread. The bobbin does not partake of the motion of the spindle, but is retained by the friction of its lower end resting on the piece of wood 17, and this is increased by a washer of leather put under it: then, as before explained of the bobbin of the roving frame, the thread, by the motion of the flyer, drags the bobbin about after it with a velocity equal to the difference between the motion of the end of the flyer, and the motion of the thread as delivered out by the front rollers. When the frame has been so long at work, that the bobbins become filled with thread, the child in attendance, by the handle of the lever 10 (*fig. 5.*), disengages the binder *a*, of the four spindles from its axis *n*, and then they, as well as the head of the rollers belonging to them, stop, and the child breaks the thread; then pulling off or unscrewing the flyer, he lifts off the bobbin, puts on an empty one, on which the end of the thread is previously lapped to make a beginning: the flyer is next fixed on, the thread passed through the eye at the end of the flyer, and it is ready to work again: the eye of the flyer is made open at one part, being curled in the manner of a cork-screw just at the end so that the thread can be hooked in and out of it by the child, but is in no danger of getting out by the motion of the flyer in its work. When a thread accidentally breaks, it is not always necessary to stop the spindle to unite it, but the attendant takes hold of the broken end which belongs to the bobbin, and draws off a considerable length, a yard for instance, from the bobbin, and breaking it, throws this away, because it has every chance of being unfound: then taking the end in the finger and thumb, and applying it against the end of the roving which is coming through between the rollers, leaving them overlapping a small quantity, and letting them go from the finger and thumb, the ends are instantly twined together, and united into one found thread. But this requires some dexterity, for if the end of the thread is held so long between the fingers in applying them together, that the roving coming through the rollers advances the length of the fibres of the cotton before it is let go, and suffers the spindle to twist it, the fibres will part and the thread breaks asunder, or is never formed at that part; it is therefore necessary to catch the roving as close as possible to the rollers, and apply the end of the thread quickly to it, then letting them go instantly, the fibres are twined in with each other, and the union takes place so perfectly, that it cannot be afterwards discovered where the joint was made. The lower rollers are made of cast iron, turned extremely true, and fluted by an engine; the upper rollers are also cast iron, but are covered with leather in the acting parts, so that this soft substance holds the cotton more firmly upon the flutes of the lower one than any other method would, as the roving is not liable to lap round the rollers like the sliver of the drawing frame. No clearer is used; but instead thereof, a small wooden roller covered with leather is placed over, between the front and middle roller, but it merely lays upon them, having no pivots or support; its surface is rubbed over with chalk or whiting, and this it communicates to the leather of the upper roller, and is found to improve their action, probably by not suffering the cotton to slip beneath the rollers: *fig. 4.* shews, that the middle and back rollers have their weights to keep down the upper rollers upon them in the same manner as the front rollers; but the weights are very different, the front weight, 6, being 20lbs., whilst the middle weights are but a few ounces, and the back rolls have a weight of

2lbs. The reason for the front roller requiring so great a weight is, that it is necessary for them to press and hold every one of the fibres of the roving while passing through them extremely tight; because if it only held a few in the middle of the roving, the others towards the edges of the roving might, by the twirling, be drawn out before their ends were fairly twined into the thread, and this would render the thread fuzzy in its whole length: the instant the foremost end of a fibre comes through between the rollers, it should, by the twine of the spindle, be twined over the middle of some other fibres which are coming through; and over the ends of others which have altogether escaped the roller, and the smoothness of the surface of the thread altogether depends upon this being done instantaneously on the foremost end presenting itself through the rollers; for the effect of all the preceding operations has been to disperse the ends of the fibres equally, so that they effectually break joints with each other, and then being equally twined, it forms a thread of equal strength in all parts.

The numbers of the wheel-work for the rollers of the roving frame, are varied with every different number of cottons which is to be spun; the draught being altered, when requisite, to produce such an extension of the sliver in passing through the rollers, as will make the roving, when finished, 4.3 times the weight (length for length) of the yarn it is to be spun into. This is a pretty general rule in cotton-mills, and the roving is occasionally measured and weighed, to ascertain if the machines are drawing the proper quantity, and if not, the pinions are changed for others which will produce the proper degree of extension. It is in this stage that the size of the yarn is determined, and the spinning frames have, in general, the same draught; but the velocity of the spindles with respect to the roller, so that they will give a greater or less degree of twine to any given length, is varied in spinning different kinds of twill, whether hard or soft twill. The alteration is made by employing larger or smaller pulleys, or whirls, on the spindles which cause them to revolve with a slower or quicker motion. Neither do the rollers of the spinning-frame give out the same quantity of roving in a given time when spinning coarse or fine goods, or when spinning very high numbers, as No. 60: the front rollers are adapted by the wheel-work to revolve at the rate of 35 times *per* minute; but for coarser goods, some of them will turn 60 times *per* minute: this is because a fine thread requires more twill in a certain length than coarse.

The frame from which the drawing was taken contained ten heads, or forty spindles, on each side, the frame = 80, and the frame on the opposite side of the drum, to be driven by the strap *b*, making 160 spindles, actuated by one cog-wheel *A*.

The construction of the locking bayonet *d*, for connecting the drum with the main spindle, we have explained; but one circumstance was then unnoticed, *viz.* that the bar *f*, *fig. 1.* is not permanently fixed to the wheel *g*, but that the wheel has a groove turned in the edge of it like a pulley; and an iron hoop or clip, made in two halves, screwed together, is fitted round the wheel in this groove, and to this clip the cross-bar, *f*, is united, by the ends of it turning down, and being received between the ends of the clip, the same screw-bolts holding all together. The consequence of this construction is, that the machine is not suddenly jerked into motion when the bayonet is let down, and intercepts the arm *f*, which is revolving rapidly with the spindle and wheel *g*: instead of jerking the frame, the bar, *f*, for a moment becomes stationary against the point of the bayonet,

MANUFACTURE OF COTTON.

bayonet, the wheel, *g*, slipping round within the clip, but the great friction of this soon sets the machine quietly in motion; and when it arrives at its full speed, the friction of the clip is sufficient to keep it in motion, without slipping any more, unless an accident happens, and then it is very useful, as it prevents the machine being broken.

The *throstle spinning-frame* is delineated in *Plate X.* of which *fig. 1.* is a section taken across the length of the frame; *fig. 2.* is an end view, and *fig. 3.* is an elevation of the machine in front. After the minute description we have given of the construction and operation of the roving-frame and water-frame, it will not be necessary to be very diffuse in our account of this machine, which has the same parts as those machines, but only differs in dimensions and proportion. The same letters of reference are employed in all the figures, and *A A* represents the live and dead pulley actuating the whole, fixed on the end of the spindle of a long tin cylinder *B*, which is called the throstle, and turns all the spindles and other machinery at once. On the main spindle of the throstle a pinion, *a*, is fixed: this turns a wheel *c*, which has a pinion, *b*, fixed on it, turning the wheels *D* and *E* (*fig. 2.*) by the intermediate wheels, *d*, on one side, and *e* and *f* on the other. The wheels, *D* and *E*, are fixed on the ends of the spindles of the front rollers *X*, as is plainly shewn in *fig. 3.* These rollers are made in lengths, which serve six spindles, and the lengths are united by connecting boxes, as shewn at *F*, to other lengths, so that one train of wheel-work, *a C b d e f E* and *D*, will turn the front rollers for 112 spindles, or 66 on each side of the frame, and then the rollers are made in 11 lengths. Some frames are longer, others shorter than this. Our drawing only contains 12 spindles, and two of these at each end are removed, to shew the works inside of the frame: at *g* a pinion is fixed on the spindle of the front roller, and turns a wheel on the end of the middle roller, by an intermediate wheel and pinion on a stud; and at the opposite end of the middle roller is a wheel *h*, turning the back roller with its proper velocity by means of an intermediate wheel, so that the motion of the rollers in this frame is exactly the same as in the water-frame. The spindles, *l, l*, are all driven by bands from the throstle cylinder *B*, the manner in which they cross being shewn at *k*, *fig. 1.* The bands are very loose, and, as the figure shews, are inclined, so that their weight tends to draw them tight, and turn the spindles, *l, l*, about with the proper velocity; but still the child attending the machine can, by pressing his knee against the whirl, as the pulley is called, stop the motion of any one spindle for a moment whilst a broken thread is repaired, the band slipping round it all the time. The spindles, being exactly the same as the water-frame, need little explanation, more than to enumerate their parts, which are, the bobbin *m*, the flyer *n*, stuck by friction, or else screwed on the top of the spindle, and its branches ending in a curled hook, through which the thread is passed to the bobbin. This is fitted quite loose on the spindle, and rests its weight on a piece of wood *o*, fixed to the underside of a rail *N*, which rises and falls, to lay the thread regularly in a coil upon the bobbin, as fast as it is taken up thereby. The rise and fall are thus produced: the two rails, *N, N*, on opposite sides of the frame, are suspended by iron rods, *p, p*, from horizontal levers *G*, which are mounted on an axis, extending the whole length of the frame, and having as many of the levers, *G*, upon it, as are necessary to suspend the rail, *N*, without bending. *H* is an iron rod jointed to the lever *G*, and coming down to a short lever *l*, which, at the opposite end to its connection with *H*, rests on the surface of the

heart *R*, fixed on a spindle, which is turned by the following train of wheel-work. The spindle of the wheel and pinion, *C b*, passes through the frame, and by a pair of bevelled wheels, *L* (*fig. 3.*), turns a vertical axis *M*, on the lower end of which is an endless screw, giving a slow rotation to the spindle of the hearts by a tooth-wheel, *m*, thereon, which is turned round one tooth by every revolution of the endless screw. A heavy weight, *P* (*fig. 1.*), is suspended from the lever, *G*, to counterbalance, and cause the end of the lever, *I*, always to press upon the surface of the heart *R*, which, as it turns round, elevates and depresses the bobbins on the opposite sides of the frame alternately. The joints of the levers, *G* and *I*, with the rods, *H* and *p p*, are made, as the figure shews, adjustable; that is, the centre pins are fixed to the levers by fitting in grooves, and are held in by nuts, so that they can be fixed at different distances from the centre, to accommodate the acting radius of the levers, so that the motion given by the heart, *R*, may be made to correspond with the length of the bobbin between the shoulders.

The bobbins for the roving are set up in a frame at *S S T*, between the two sets of rollers, *X. X*, and the roving is conducted immediately between the back rollers: but, as it goes through the same process as before described in the water-frame, it is needless to repeat it. The traverse motion, to prevent the cotton wearing away the rollers in any one part, is sometimes omitted; but we have seen throstle frames in which the whole of the frame *S T*, consisting of one board, *S*, below, and another, *T*, above, connected by proper pillars, together with all the bobbins of rovings, had a small traverse motion, which is found to be a great advantage in the wear of the rollers.

Respecting the comparative advantages of the throstle-frame and the water-frame, cotton-spinners are divided in their opinions: the simplicity, and consequently low price in the first erection of the throstle, is its recommendation, and it is generally stated to be driven with far less power, because it has fewer parts. To set against these advantages, it is said, that when the bobbins are filled, and require to be changed, the whole frame of 112 spindles must be stopped at once, by shifting the strap to the dead pulley *A*; whereas in the water-frame, any four spindles can be stopped together, by casting off their binder; and it is only necessary to stop the whole frame by the casting off the great drum, when the frame is to be repaired, or is out of use for a day, or longer period.

We have now explained the manner of spinning cotton into a thread by the water-frame, and shall proceed to describe the construction of the other method of spinning, *viz.*

The Mule.—This machine was introduced by a Mr. Crumpton, who lately received a reward of 500*l.* from parliament for the invention, which, as before mentioned, consisted only in the combination of Hargreave's spinning jenny with sir Richard Arkwright's drawing rollers. *Plate XI.* contains drawings of one of the best constructions of this machine, in which *fig. 2.* is an end view of the whole machine, and *fig. 1.* an end view of the carriage alone. *Fig. 3.* is a front view, and *fig. 4.* is a view of the operative parts detached: *fig. 5.* a similar view in another stage of its operation. As this machine is extremely complicated in its movements, it will first be proper to explain these movements before entering upon the machinery which causes them. This is shewn in *figs. 4* and *5*, where *W* represents a bobbin of the roving frame let up in a proper frame, and the roving is conducted from it, through three pairs of rollers, *A, B*, and *C*, which have the same draught as the rollers

MANUFACTURE OF COTTON.

rollers for the spinning-frame, and are moved by similar wheel-work: but the upper rollers, *a, b, c*, are weighed down in a different manner: thus, *d* is a piece of metal resting on the neck of the front roller, *a*, at one end, and the other end upon the middle of a second piece *e*, which bears upon the necks of the other two pairs of rollers, *b* and *c*; then an iron rod *f*, coming down from the piece *d*, loads all the three upper rollers *a, b, c*, at once, by means of a lever *g*, which is hooked beneath a fixed rail of the framing supporting the rollers at one end, and the other is made with a heavy knob, so that the purchase, or leverage of this piece *g*, draws down the wire, *f*, with sufficient force to load all three rollers with their relative forces: thus it is plain the roller, *a*, must bear the principal weight of the lever *g*, because the wire, *f*, is nearer to the roller *a*; but as it acts upon the piece, *e*, with a considerable length of leverage it bears lightly upon it, and this again bears upon two, and therefore still less upon either, the weight of the end of *d* being divided upon two rollers *b, c*; but it bears most powerfully upon *c*, the point or end of *d* being nearest to that roller, so that the operation of all these pieces is to load the three rollers nearly in the same proportion as the rollers of the spinning frame: but this proportion can readily be altered by shifting the acting lengths of the levers.

The roving, after passing through the rollers, is taken up by the spindle D G: this is placed rather inclined, but without any bobbin or flyer, like the spindle of the water frame; it is merely a plain conical arbor, supported at its point, or toe, in a step made on the rail, E, of the frame, and in a bearing at F, against another rail. It has nothing to keep it up against this bearing, the draught of the band, which passes round the pulley *b*, and gives motion to the spindle, being sufficient for this. The end of the thread is merely lapped round the upper end of the spindle, and its accumulation upon itself soon forms a mass G, which is called a cop, or coppin. Now it is evident that, from the inclined position of the spindle, it will, when turned round, give twist to that part of the thread which is between the end of the spindle and the roller A, although the spindle and the direction of the thread do not coincide, because, when the spindle is turned, the thread will slip over the top end of it and receive a twist, without winding up upon the cop; but when it is required to wind up, the thread, or wire H, is pressed down upon the thread. This removes it from the end of the spindle to the middle of the cop, as shewn in *fig. 5*, and then the motion winds up the thread upon the cop instead of twisting it. The wire, H, is extended at the end of a lever H I, moveable on a centre I, in the manner shewn in *fig. 5*, but when left at liberty, the weight of the opposite end of the lever restores it to the position *fig. 4*, and then the spindle twists the thread instead of winding it up.

The operation of the machine is this: the rails E and F, supporting the spindle, are part of a carriage or frame carrying above 100 such spindles, and moving on wheels which traverse on railways to and from the rollers in a direct line, for the extent of a yard and a half. Now suppose it wheeled home, that the ends of the spindle are close to the front roller A, then suppose the rollers set in motion, they take in the roving from the bobbin W, and draw it out or extend it eight or more times, giving it out between the front roller A, to the spindle G, which, with its carriage, recedes, by the movement of the machine, from the rollers, taking up the thread as fast as it comes out between them; and, at the same time the machinery draws the spindle back, it turns it round rapidly, giving twist to the

thread as fast as the rollers deliver it out, and thus producing such a compression of the fibres by twisting them round each other, as will form a thread of sufficient strength to bear *stretching*. This means, that when a yard of thread has been given out by the rollers their motion ceases, so that they deliver no more, but the spindle continues to recede from the rollers to the further distance of a yard and half, twisting the thread all the time it stretches it out in length, till it forms a fair and strong thread. The twisting motion of the spindle then stops, as does also the drawing-out movement of the spindle, with its carriage. Thus one yard and a half of thread is made and finished. The attendant to the machine now thrusts the spindle, with its carriage, home to the rollers, holding the wire H, done in the manner shewn in *fig. 5*, and at the same time turning round the spindle at such a rate, that it will wind up the thread upon the coppin, and the wire H, which is held down by the hand, is so humoured, as to make the thread wind up with regularity. The rotatory motion given to the spindle is, in this instance, done by the other hand of the attendant, and is so accommodated, as to wind up the thread just as fast as the advance of the spindle towards the rollers requires, and no more; but when it arrives close to them, the wire, H, is raised up, and the machinery is put in motion again, the rollers begin to draw out, and the spindles to recede, turning all the time. The mechanism by which all this is effected is described by *figs. 1, 2, and 3*; first, see *fig. 2*, where K is a live and dead pulley for the endless strap actuating the whole by the power of the mill. The pulley is mounted on a short spindle, having a winch or handle, L, at one end, and on the other a large pulley M, which has a number of different-sized grooves formed round it, to receive an endless rope *i*; see also *fig. 2*: this rope, after making a half turn round M, passes under a wheel *k*, fixed on a pin or stud projecting from the frame. From this wheel the rope, *i*, proceeds to another wheel, *l*, at the opposite end of the frame, and returning from this goes over a wheel situated close behind *k* on the same centre pin. The ends of the rope are then joined, and it forms an endless band, which, when the strap is cast on the live pulley *k*, and the wheel, M, turned by it, the rope, *i*, constantly runs in a straight line from the wheel *k* to *l*; but in this passage the rope makes a quarter turn round a wheel *m*, upon a vertical axis, which is mounted on the frame or carriage E F, for the spindles D, G, shewn separately in *fig. 1*. The rope, *i*, not only passes round the wheel on this spindle, but goes forwards into the carriage, and passes round a groove upon the upper end of a vertical drum, (not seen in the figures,) which has several bands upon it, each driving two spindles, D, by passing round the pulleys, *b*, of two of them, as shewn in *fig. 3*, in which it is also seen that the bands are all at different heights, that they may not interfere with each other upon the drum, but each take its proper place upon the length thereof. The carriage runs upon four wheels 1, 2, (*fig. 2*.) two of which are placed at each end, and run upon an iron railway, so that the carriage containing all the spindles and drums runs backwards and forwards, to and from the rollers, for the length of a yard and half. But during this motion, the power of the mill is all the time conveyed to turn the spindles by means of the endless cord *i*, which, as before-mentioned, making a straight line from the wheel *k* to *l*, will not be affected by the motion of the carriage, but will always circulate round the several wheels, and give motion to the drum which turns the spindles: 4, (*figs. 1 and 2*.) is an iron bracket, supporting the axis I I' of the lever, H, *fig. 4*, which supports the wire H, and as many of these levers are fixed on the axis I, as shewn in *fig. 3*, as are sufficient

MANUFACTURE OF COTTON.

cient to make the wire H, stiff enough to press down all the threads together, in the manner of *fig. 5*. The remaining parts of the carriage, being only its frame, are evident from *fig. 1*, and need no farther notice, except a double pulley; that is, a pulley 5, with two grooves upon it, fitted on a stud or pin in the underside of the frame, between the two wheels 1 and 2. The use of this pulley, with its ropes, as we shall describe, is to make the whole carriage move parallel, or both ends equally, which, in a carriage of twenty feet long, requires some nicety. As the two wheels 1 and 2 cannot be placed very distant, and therefore give little steadiness to a carriage of such a great length, the parallelism is thus preserved: a rope, 6, is made fast at one end to a fixed part of the framing, then passes a quarter round the upper groove of the pulley 5, and runs along the whole length of the carriage, and turns a quarter round a similar pulley 7, *fig. 3*, and then goes forward parallel to its first direction, from 6 to 5, and is made fast to the frame in a similar position to 8, *fig. 2*, but at the farther end of the frame. In the same manner, another rope is fastened to the frame at 8, and making a quarter turn round the lower groove of the pulley 5, proceeds the whole length of the carriage, makes a quarter turn over the pulley 7, *fig. 3*, and proceeds parallel to the first direction, from 8 to 5, and is made fast to the frame in a similar position to 6, but at the opposite side of the frame. The two ropes cross each other in the centre of the carriage, and they always pass over opposite sides of the pulleys 5 and 7. Their effect, which is not easily explained without a separate figure on purpose, is to make the carriage move equally at both ends, for it must do this, unless one or other of the ropes slip upon the grooves of their respective pulleys 5 or 7, and this they will not do if strained tight. We have clearly stated the passage of the two ropes 6 and 8, and the mechanic who knows this, will readily see the manner of its operation, though it is difficult to explain it by words only.

We must now attend to the wheel-work for the rollers: a bevelled wheel *o*, fixed close behind the wheel M, on the main axis, turns another on the end of an inclined axis *p*, *fig. 2*, at the opposite end of which is another bevelled wheel, turning *q*, fixed on the extremity of the front roller; which being connected with the middle and back rollers by the same wheel-work as the throttle frame, and the rollers being of a similar construction, demand no further description, except what we have already given in *fig. 4*, of the weights for pressing down the upper rollers. When the rollers are to be cast out of gear, it is done by disengaging the wheel, *p*, from the wheel *o*; for which purpose the bearing for the upper end of the inclined axis carrying the former, is made in the upper end of a lever *r*, which moves on a centre pin, fixed in the standard supporting the bearings for the axis of the wheel M: the lower end of this lever is connected with the end of a short lever *s*, moveable on a vertical centre pin fixed in the frame: this lever has an arm proceeding from the centre at right angles with that seen in *fig. 2*, and is therefore hidden behind the centre, its form being shewn at Z, which is a plan of this lever. From this second arm a wire proceeds to the pendulous lever P *t* *v*, moveable on the centre pin *t*. Now by moving the end, P, of the lever, P *t*, away from the wheel, M, it draws the wire and arm of the lever *s*, the other arm of which acting upon the lower end of the lever *r*, to throw it inwards, throws the upper end outwards, and brings the wheel, *p*, in contact with the wheel *o*, so that the inclined axis, and the front rollers also, are set in motion, as long as the end of lever, P, is kept held towards the end of the

frame. This holding is performed by its arm *v*, which, as in the figure, may be hooked under and kept down by a small catch *w*, and from this a fine wire, *g*, proceeds back to the opposite end of the frame, and is then linked to a short lever, which is fitted loosely on the same centre pin which connects the lower end of the lever, *r*, with the arm of the lever *s*. This lever is shewn at *z*, in the separate figure Z, but its use is only to support the end of the wire *g*, and keep it up, so that a part of the carriage of spindles, in running back, may, by intercepting the end of it, draw the wire and the catch *w*, thus relieving the arm, *v*, of the lever P, and this, as before explained, throws the wheel, *p*, out of gear, and the motion of the rollers ceases. On the return of the carriage towards the rollers, a piece of wood, *x*, fixed to it, runs against the lower end of P, and moves it back so far that the catch, *w*, engages it. This sets the rollers in motion, which they continue, until, in the retreat of the carriage, a piece of iron *y*, *fig. 1*, projecting up from it, catches the short lever, *z*, near *s*, supporting the wire *g*, which being thus drawn, disengages the catch *w*, and then the wheel, *p*, is cast out of the gear with *o*, as before-mentioned, and stops the motion of the rollers. The motion for drawing out the carriage from the rollers is thus performed: a cog-wheel R, which has a pulley fixed on against it, receives an endless rope, 10, passing round a pulley, 11, at the end of the frame. One part of the endless rope is tied to an iron arm projecting from the carriage, so that when the wheel, R, is turned round, by engaging its teeth with a cog-wheel fixed upon the end of the front roller, the endless rope, 10, traverses, and moves or draws the carriage out with it. The wheel R, which is called the Mendoza wheel, is made to lock in or out, by fitting it on a centre pin, which is fastened into the upper end of a lever T, (see the separate view,) moveable on a pin fixed in the frame. The lower end of this lever is moved by a horizontal lever, seen endways near V, which represents its vertical centre pin or stud. The end of this lever, which is before the stud, or nearest the eye, is connected by a strong wire with the lever P, and therefore, when this lever is pushed by the motion of the carriage, it engages the Mendoza wheel, and draws out the carriage, at the same time that the rollers are put in motion, and give out the roving between them; but the carriage, being drawn out to the length of roving which it is to have to stretch and spin the Mendoza wheel, is not disengaged the moment the rollers are cast out by the wire *g* and catch *w*, in the manner we have just described, because the lever, T, carrying that wheel is provided with a catch, similar in its properties to *w*, that is, it holds the wheel, R, in its work until the carriage has run a yard and a half, and then it seizes a wire communicating with this catch, thus disengaging the catch holding up the lever T: the Mendoza wheel then falls back, and the drawing-out movement of the spindles ceases. This catch and wire are not shewn in the figures, as it would produce much confusion, but being so exactly similar in this action to the catch *w*, and its wire *g*, they may be easily imagined.

We have now to describe the manner in which the rotation of the spindles is cast in and out. The reader, if not confused by the complication of this machine, may remember that we explained the connection from the wheel M, by means of the endless cord *i*, to the wheel *m*, and thence to the vertical drum turning the spindles. When this motion is to be thrown in and out, it is done by shifting the main strap, driving the whole machine on the live or dead pulley K, *fig. 3*. The strap is guided by passing through an eye or loop at the extremity of a lever, W Y, fixed on a

vertical

MANUFACTURE OF COTTON.

vertical axis 12. On the lower end of this axis is a long lever 13, and at right angles to this a shorter lever, which being seen endways is not apparent, but it advances some distance forwards from the centre of the lever, and has a wire, 14, jointed to it, which is extended to a lever 15, against which the carriage runs when it is pushed home, and the spindles are close up to the front rollers. When this happens it draws the wire 14, which acting on the short lever of the axis, 12, turns it round, and the lever Y W with it, shifting the main strap from the dead to the live pulley K, and thus putting the whole machine in motion; at the same time that, by the operation we have before explained, the Mendoza wheel is thrown in, and also the movement of the rollers. The former of these draws back the carriage, till, as described, the catches are released, and the movement, first of the rollers, and then of the Mendoza wheel, are thrown out. At the moment before this happens, the carriage intercepts the end of the lever 13, which is formed like an inclined plane; it is therefore thrown outwards by the carriage running against it, and the end of the lever, W, being at the same time moved, it shifts the strap upon the dead pulley, and the motion of the whole machine ceases. The attendant to the machine now takes hold of the handle L, and pushes the whole carriage back again, till the spindle comes close home to the rollers; then by the carriage striking the levers 15 and P, it shifts the strap to the live pulley, and puts the spindles all in motion together, at the same time casts, in the motion of the rollers, to give out the roving; and also it casts in the Mendoza wheel, which traverses back the carriage and all the spindles to take up the roving as fast as it comes from the rollers, twisting it by the motion of the spindles all the time.

To describe the operation of this ingeniously constructed machine, will be only to recapitulate movements which we have repeated several times over; but this recapitulation will give the order in which they succeed each other. The man or woman who attends the mule stands in front of the spindles, at such a distance from the right-hand end of the frame that he can conveniently reach the handle L. In the other hand he holds the axis, I, of the wire H. Suppose, to commence, that the spindles are close to the rollers, then the movements succeed each other as follow:

1. The lever 15, being thrust back by the carriage running against it, draws the wire 14, and by the lever, W, shifts the strap upon the live pulley, putting the wheel M, and the wheels *k*, *l*, with the endless rope *i*, the wheel *m*, and all the spindles in motion.

2. The end of the lever, P, being pressed by the carriage, engages the wheel for the motion of the rollers, and they begin to deliver out the roving at the same time.

3. The Mendoza wheel is cast into gear, and begins to cause the carriage to retreat from the rollers as fast as they give out the roving. These first, second, and third motions, all happen at the same instant.

4. The spinning of the rovings is now performed by the above motions, the spindles twisting the rovings as fast as they are given out; but the motion of the rollers is so quick, that the twist now given is slight, but having thus extended, or taken out, a yard in length from each spindle to the roller, the piece of iron *y*, *fig. 1*, on the carriage, meets the end of the lever *s*, and

5. Disengages the wheel-work for the rollers, which are therefore stopped, and deliver out no more roving; but the retreat of the carriage and the twine of the spindles continues for another half yard, stretching out the thread, and twisting it, till the piece of iron, *y*, meets the catch of the next wire, which is not drawn in the figure, and

6. Disengages the Mendoza wheel, consequently the carriage draws out no farther. The thread being sufficiently extended and twisted,

7. The carriage takes hold of the end of the lever 13, and thus shifts the strap to the dead pulley K, *fig. 3*, and the motion of the whole machine ceases.

8. The attendant, by turning round the axis, I, of the wire H, presses down all the threads together from the points of the spindles to the middle of the coppin, in the manner of *fig. 5*; then

9. Takes hold of the winch L, to regulate the winding of the thread on the coppins, when he

10. Drives the carriage home to the rollers. In this motion the spindles all revolve, and lap up the thread upon the coppins. The revolution is caused by the endless rope *i*, which may, when the machine is standing still, be considered as a stationary rope acting upon the wheel *m*, and the drum for the spindles, and as their centres traverse, turning them all round, on the same principle as a carriage wheel is turned by rolling on the stationary road. In like manner *m* is turned, by moving along while the rope, *i*, is immovable. Now the quantity of motion, or the number of revolutions the spindles will make during this return of the carriage, is, in all cases, the same, and the quantity of thread to be wound up is always the same; but it is evident that it will require a greater number of revolutions to wind up the length ($1\frac{1}{2}$ yard) of thread, when winding upon the spindle, or upon the circumference of a small coppin, than when the same coppin is increased by the accumulated thread to ten or fifteen times the size of the spindle. To accommodate this, it is necessary for the spinner to have the handle, L, in his hand, because he can, by turning this one way or the other, add or diminish so much to the number of turns the spindle will make, as will just take up the thread as fast as the carriage advances towards the rollers. Thus, at first beginning, when the coppins are small, the handle, L, will require to be turned forwards a considerable quantity, to make them wind up the thread sufficiently fast; but as the size of the coppins increase, they will come to such a diameter, that the handle requires to be held quite still. The motion given to the spindles by the return of the carriage, being then just equal to wind up the thread at the proper rate, any increase of the dimensions of the coppins after this will require the handle, L, to be turned backwards, to diminish the motion of the spindles, or they would wind up too fast, and break the threads.

The spinner accommodates the motion of the handle, L, so exactly by habit, as to keep the threads always to that degree of tension as will make the coppin compact, but not injure the thread; at the same time by the other hand, which holds the spindle of the wire H, he lays the thread regularly on the length of the cop.

The carriage, having with these precautions been wheeled up close to the rollers, the several operations are repeated as before; and thus the mule continues to spin a yard and a half upon each spindle every time it is drawn out, and then wind it up on the several coppins. A good spinner will draw out 3000 times per day of a mule with 240 spindles; and many women will attend two machines, having them placed opposite to each other; and while one is drawing out she will thrust home the other. This makes 108,000 yards per day upon each mule, or both together will make more than 1200 miles to be spun in one day by one woman; who, on the old method of the hand-wheel spinning, on which the mule is an improvement, would only have managed a single spindle, instead of 480; and this single spindle would not have spun half the quantity of any one in the mule; and
with

MANUFACTURE OF COTTON.

with respect to the regularity and accuracy of the thread no comparison can be drawn. A mule of 240 spindles has nine drums in the carriage to turn them; all the length, therefore, is nine repetitions of *fig. 3*, which only contains the spindles turned by one drum.

The motion of the mule can at any time be stopped, if a thread break, or any other accident happens, by means of a long wooden rail, *Y*, which is joined to the end of the lever *W Y*, and extends along over the whole length of the rollers, so as to give the spinner the means of stopping the mule when standing opposite to any part of its length; for it is evident, that by thrusting this rod one way or the other, the strap will be shifted either on the live or the dead pulley, stopping or putting the wheels in motion at pleasure.

The thread spun upon the mule is much softer, and has a smoother surface than the water-twist: this is owing to the manner in which the extension of the thread is made, after it has been twisted slightly, and the fibres thereby compressed together in some degree; for the effect of stretching a slightly twisted thread is, to draw all the ends of the fibres into it. All these fibres having assumed a spirally curved form in the thread, by drawing or stretching them out in the length of the thread one among another, these fibres are drawn along with a spiral movement, and all their ends are thus brought into, and concealed in the body of the thread. This operation, at the same time it makes the surface of the thread even and smooth from projecting fibres, increases the strength of the thread by bringing them all into use; and the strength obtained by this means does not require the thread to be twisted hard, but leaves it soft and pliable, which is the great recommendation of the mule-twist.

The thread thus spun, either by the water-frame or mule, has many other operations to go through to prepare it for the market, where it is to be sold to the weaver or manufacturer. The chief end of these operations is, measuring it out in lengths, weighing it to ascertain the number, and packing it up for carriage. The first machine the thread is taken to after spinning is

The Reel; see *figs. 1 and 2 of Plate XII*. The former being an elevation of the end, and the other an elevation in front, a very short explanation of this machine will suffice; its framing and some other parts being evident. *A A* is a row of the bobbins of the spinning frame, or for mule-twist, the coppins of the mule stuck upon pins, on which they will revolve freely and give off their thread. *B, fig. 1*, is another row placed behind the former, and arranged in the intermediate spaces between the bobbins of the first row, which arrangement is necessary, because the bobbins would touch each other if all placed side by side. The threads for these bobbins are conducted between several pins or wires, stuck up in a rail of wood *D*, and each thread is twisted once round one of these pins, that it may be drawn off with such a degree of force, from the friction thus occasioned, as will cause the thread to lap or wind with a sufficient tension upon the reel *E E*, which consists of a horizontal shaft *E*, from which three sets of arms, *F*, proceed, supporting six rails, *G, G*, parallel to the axis, and upon these the thread is wound, as shown in the figures at *J*. The dimensions of the reel is such, that it takes exactly a yard and a half of thread to make one turn round it: this, therefore, is the measure of length, and the mechanism which remains to be described is for the purpose of counting the number of revolutions it has made. The reel is turned round by means of a cog-wheel, *H*, on the end of the spindle: this is turned round by a wheel *K*, on the

axis of which is a pulley *M*, to receive an endless rope, which is turned round by the mill; but the bearing for the pivot of the axis, *E*, is fitted in a groove, formed on the top rail of the frame, so that the wheel, *H*, may, by sliding the bearing in this groove, be disengaged from the teeth of the wheel *K*, and then the movement being thrown out of gear, the reel stops. On the opposite end of the axis of the reel, a pinion, *a*, of 14 teeth is fixed, which turns a bevelled wheel of 28 teeth on the upper end of a vertical axis *b*, which has an endless screw upon it, turning a wheel, *d, fig. 1*, of 40 teeth, on the axis of which is a pinion of eight leaves, turning a wheel, *e*, of 56 teeth. This wheel has a small circular ring fixed on the face of it, which is formed like a snail on the front edge, that is, its surface is not parallel to the plane of the wheel, but is inclined to it in such an angle, that in turning round it operates upon a lever, *f*, to move it backwards and forwards, and this motion is, by means of a vertical lever, *h h*, communicated to the rails, *A B* and *D*, at the top of the reel, which carry the bobbins, and also the pins, *D*, that guide the thread, and having thus a short traverse motion parallel to the axis of the reel, the threads are laid regularly by the side of each other, without overlaying each other in one place, as they would do without this motion, and by thus enlarging the diameter of the reel, the thread that winds upon the measure would be incorrect.

By calculating the numbers of the train of wheel-work, *a, b, d*, &c. which we have before explained, *viz.* by multiplying the number of all the pinions together, and the number of all the wheels together, and dividing one sum by the other, thus, $14 \times 1 \times 8 = 112$, the product of all the pinions: again, $28 \times 40 \times 56 = 62,720$, the product of the wheels. Divide 62,720 by 112, and the result is 560; therefore the wheel *e*, of 56 teeth, will make one turn for 560 turns, or bouts of the reel. The wheel *d* makes only one-seventh of this number, or once for 80 bouts; and a pin being fixed in the back of its rim, seizes the tail of a bell, *m*, once for every turn it makes, consequently this bell rings at every 80 bouts of a yard and a half each, = 120 yards of thread wound upon the reel. The reeler, in beginning, makes the end of each thread fast to one of the rails, *G*, of the reel, then casts it on, and sets it going until the bell, *m*, rings; it will then have made 80 bouts, or reeled 20 yards, which is called a ley. The reel is stopped the instant the bell rings, and every one of the leys of thread, *r, r, fig. 2*, is tied up by a piece of thread to keep these 80 bouts distinct; then the reel is set on again and another ley reeled, which is tied in its turn; and when seven leys have been thus done, it makes 560 bouts, or 840 yards, which length is called a hank: the seven leys composing it are tied all together, the ends of the thread cut off, and the hanks are removed from the reel. They are got off by what is called striking the reel, to do which, the arms supporting one of the rails, *G*, are divided across in the middle of each, and united by hinges. When the arms are set straight, and kept so by a small bolt, the reel is of the true dimensions; but by withdrawing the bolt, and bending the arms on the hinges, the rail falls in towards the centre, and the reel is so diminished in size, that the hanks hang slack upon it, and can easily be slipped off at the end of the reel, which is lifted off its bearings for that purpose.

A reel usually winds 30 bobbins at once, and the principal care of the attendant is to watch the bobbins, supplying others, and tying the ends of the threads as fast as they are exhausted.

The hanks are now twisted up into a knot, by catching one end of them over an iron hook fixed to the wall, then putting

MANUFACTURE OF COTTON.

ting a small iron rod in the other end, the hank is twisted up very hard, using the rod as a lever to turn it round. To prevent its untwisting again, it is taken by the middle of its length, and without suffering the ends to entwine it is doubled, then the ends are released, and the two halves twist over each other, forming a bundle or knot of thread, resembling a piece of thick rope, about eight or nine inches in length, and perhaps two inches girt. The hanks, being thus all knotted, are weighed, to ascertain their number. The weighing instrument consists of a short pendulum, from which an arm proceeds on each side, at top passing through the centre of suspension, so that it resembles the letter T. From one of the horizontal arms a hook is suspended, by which the hank is hung on; and at the end of the other arm is an index pointing to an arch which is divided, and has figures upon it, shewing how many of such hanks (as the index is brought to by hanging any one upon the hook) will weigh a pound. The divisions are made by experiment, and frequently verified by means of small leaden weights, which the overseer is provided with.

As fast as the number of the several hanks is determined by this index, they are thrown into different bins or shelves, and when they are to be made up for market, as many hanks of any number as will weigh ten pounds are counted out, weighed, as a check upon the weighing instrument, and packed up in paper, forming a small square bundle, which is made compact and tight in the bundling-press. This is a small square chest, of about eight and a half inches by nine and a half, formed of vertical iron bars set upon a table, and a lid of iron bars shuts down over the top, with bolts or other fastenings. The bottom of the chest is moveable up and down by means of a rack and pinion, a screw or other means, which will enable the workman to give a great pressure upwards. The hanks are packed closely into this chest with paper round them, and the whole number being packed in, the lid is shut down and bolted upon them; then by turning a handle the bottom of the press is raised up, and compresses the bundle together into as small a compass as is required. The bundle in this state is tied round with several strings, the interstices between the iron bars composing the press leaving sufficient room for the admission of such strings, and for the knots to be tied to confine the bundle. In these bundles the greatest portion of the twist is sent to market; but what is called hard twist, must be twisted two threads together, as is also stocking-yarn. Such thread as is intended to be doubled for these purposes, is taken from the spinning-frame to the

Doubling machine, instead of the reel. Here the threads, two together, are wound upon bobbins, as preparatory to twisting them round each other. See *Plate XIII.*, *figs.* 1 and 2, which represent a doubling mill; in front *fig.* 1, and endways at *fig.* 2. A is the pulley which is turned round by the mill: this pulley is loose on its spindle, but has a clutch or locking-box at the back which connects it with its spindle, when the upper end of the lever, B, is moved towards the machine. But when it is moved the other way the machine stands still, though the pulley continues all the time to turn round. A wedge, *a*, being put on either side of the lever in its mortise through the piece of wood D, retains the pulley, A, either unlocked or locked in gear, with the spindle which is fixed in the end of a throttle-cylinder, R, and by bands turns all the spindles, *b, b*, together. The bobbins of the spinning-frame are stuck upon pins in the top rail, E, of the frame, and the threads descend to wires, *d*, round which they make a turn, two threads in company, to produce a friction, as before explained, sufficient to lay the turns on the bobbin of the spindles, *b, b*,

tight and even. The threads then go through wire staples or eyes fixed in a rail, F, situated opposite to the bobbins *e, e*, which are stuck fast on the upper ends of the spindles *b, b*, and being turned thereby, wind up the thread from the bobbins at E: the rail, F, is adapted to rise and fall parallel to itself, being attached by radial bars to an axis moving on centre pins fixed in the frame. Its motion is occasioned by an iron rod, *f*, which is jointed to it, and connects it to a lever, *g*, fixed on an axis; and at the extreme end of this is a lever, *h*, *fig.* 2, resting upon the circumference of a heart, *h*, fixed on the face of a cog-wheel *i*. This is turned by a pinion fixed against a wheel *k*, which receives its motion from another pinion upon the end of the spindle of the throttle cylinder R. By this train of wheel-work the heart is slowly turned round, and raises and falls the lever, *h*, at the same time giving a similar motion to the rail F, and by that means regularly winding the thread upon the bobbins *e, e*, which are turned rapidly round by the motion of the vertical spindles *b, b*, which receive their motion from the throttle cylinder, R, by the bands, as before described. The bobbins are such as shewn separate at X, and have a hole through them exactly fitting the conical end of the spindle, on which it ticks so fast, that the bobbin will, by the motion of the spindle, wind up the two threads together off the bobbins at E. When the bobbins are filled with double thread, they are removed to the twisting-machine, if it is intended to make stocking-yarn, or if it is to be what is called hard twist, for sewing, knitting, or mending-cotton, it is done in the water-frame, which, however, undergoes some alterations, *viz.* the spindles are made to turn about in a contrary direction to that in which they moved to spin the thread. It is done by turning the whole frame the other way about, but as this would make the rollers move the wrong way, the pinion at the upper end of the spindle of the binder is placed at the outside instead of the inside of the face-wheel on the end of the front roller. The rollers then turn the right way about to deliver the thread to the spindle, but the back and middle rollers are removed, as it is not required to draw out the thread, the rollers being merely wanted to hold the threads fast whilst they are twisted one about the other, and to deliver it regularly to the spindle, which operates in the same manner as for the first spinning, except that it twists in the contrary direction; because when any two threads are to be turned together, it must be done by a contrary twist to that which composed the two separate threads themselves. After spinning this hard twist it goes to the reel, and is treated in all respects as other twist is. When it is merely required to twine the two threads slightly together for stocking-yarn, the bobbins of the doubling-machine, when filled with double threads, are carried away to

The twisting-machine, see *Plate XIII.*, *fig.* 3, of which is an elevation endways; and *fig.* 4, another elevation taken in front. In this, A represents the live and dead pulleys turning the whole machine: the strap is conducted through an eye at the end of an iron branch *a*, affixed to a rod or beam B, which slides in guides beneath the machine, and can be moved endways by means of a lever *b*, which comes out in the middle of the length of the machine, and the attendant, by applying his foot to this lever, and moving it sideways, shifts the beam B, and the eye at the end of the branch, *a*, guides the strap upon the dead pulley: the machine then stands still. The live and dead pulley is fitted on the end of the spindle of the throttle cylinder D, which, by bands going to both sides, turns a double row of vertical spindles on each side, E *e* and F *f*, the internal row on either side being placed opposite the spaces between the outer row, so that the

MANUFACTURE OF COTTON.

the spindles are not crowded too close together. On these spindles the bobbins are stuck in the same manner as those of the doubling-mill; and the threads proceeding from the bobbins are conducted through wire eyes, which are fixed in rails, G, of the framing, then each twisted thread makes a turn round a wire fixed in the rails, H, just above G, and these have a slight traverse motion backwards and forwards, by which they lay the thread evenly upon the reels, I, K, which take up the threads, as before described, of the reeling-machine. The reels are slowly turned round by a train of wheel-work from the main spindle of the pulley A. This train consists, first, of a pair of bevelled wheels, one on the main axis, and the other at the lower end of a vertical spindle L, which at the upper end has a pinion actuating another wheel, g, upon the middle of a horizontal axis, which at each end carries a pinion, turning wheels, M, N, on the ends of the pivots of the two reels. The proportions of the wheels are such, that the reel turns once for about 24 turns of the main throstle D, or about one for every 72 revolutions of the spindles, and as the reel is a yard and a half about, the thread will be twisted about 72 times in that length by the rotation of the bobbin and the thread with it. The motion of the reel draws the thread off the bobbin as fast as above-mentioned, so that the proportion of the wheel-work determines the quantity of twist which shall be given in any certain length. The reels are provided with counting wheel-work of the same operation as that before explained in the reeling-machine. Thus, on the end of the spindle of the reel is a pinion turning a wheel *i*, on the axis of which is a screw turning a wheel *k*, and this has a pinion on it turning a wheel *m*, by means of the intermediate wheel *l*. The spindle of this latter wheel has a nail fixed upon it, which operates upon a lever *n*, the lower end of which presses against a cross-bar, connecting the rail, H, with its fellow. On the opposite side of the machine there is another similar cross-bar at the other end, and the two rails being thus united, form a frame which is supported on iron radial bars *p, p*, which move upon centre pins fixed in the rail, G, of the frame; so that the frame, with the rails H, H, has a free motion to traverse without friction, and guide the threads to lay regularly upon the reels I, K. At the opposite end of the frame a string is tied which passes over a pulley, and has a weight, *r*, suspended from it, which always draws the frame one way, and tends to keep the upper end of the lever, *n*, in contact with the snail upon the axis of the wheel *m*. This axis has also a pin projecting from it, which every time the spindle turns round, rings the bell P. The motion of the wheel-work is so calculated, that the bell shall ring once for every 280 bouts of the reel, and the size thereof is such, that this 280 bouts shall measure 420 yards, being the length of the double thread hank, *r*, equal to half the length of the single thread hank, which is, as before mentioned, 840 yards, and the number of double thread yarn, is according to the number of these hanks of 420 yards each to the pound. The reels, I, K, when filled, are struck, and the hanks taken off them in the same manner as the reeling-machine before described.

Hard twist, which is intended for sewing, knitting, or mending-cotton, after being twisted and reeled in hanks, is sent to the bleach-field, and bleached by some of the processes described in our article BLEACHING.

But the process which is most generally in use for bleaching yarn, is thus conducted: an earthen-ware retort is filled with one quart of oil of vitriol, two quarts of sea-salt, and one quart of the ore of manganese. The hood of the retort being put on and luted, it is set over a small

stove or sand-bath, and the heat soon raises from it the oxygenated muriatic acid gas, which is received in a square wooden chest, about seven or eight feet square, and as many deep, forming a small air-tight chamber, in the upper part of which the goods are suspended upon a rack or frame. The lower part of the chest, for about three feet deep, is filled with water, sometimes impregnated with a ley of pot-ash, and sometimes with lime-water, or water mixed with lime. The gas is introduced betwixt the fluid and the goods, amongst which it ascends, and by its action upon any colour they may contain, renders them white: at the same time, by occasionally immersing the goods in the fluid below, it is sought to modify the action of the acid, and prevent the operation proceeding too rapidly. This is effected by means of a pole or long rod connected with the frame on which the goods are suspended, the centre of which pole moves on a swivel fixed in a hole in the partition, or lid of the chamber, which is occasionally stopped with clay, and enables a person to raise the goods by means of a small crane, or, at pleasure, to let them down into the fluid, not always, however, without inconvenience, which occasioned it the name of the *Bellam process*, as the workmen, if they inhale the gas, are stupified.

Previously to the yarn being subjected to the action of the gas, it is boiled in a ley of pearl-ashes, then milled for twenty minutes in a fulling mill, and the hanks are hung upon the racks or cross rails of the square frame in which they are suspended, to be let down into the bleaching-chamber. This frame is, as before-mentioned, attached to a long pole, that suspends it from the crane, which being swung over the chamber, is let down therein, and the lid is closed over it, the joints being made tight with clay, and the pole coming through a hole in the lid, which is carefully made tight round it by a wet cloth. The gas is now admitted to the chamber, but the yarn is not subjected to its action more than ten minutes before it is let down and immersed into the liquor at the bottom of it, which thus defends it from the action of the gas for a few minutes, until it becomes thoroughly wetted, when it is drawn up again into the gas, and remains in it for half an hour to be bleached: it is then let down again, for a few minutes, into the liquor to wet it; it is then drawn up again, and in this manner the process continues, until such time as it is known, by experience, that the yarn will be sufficiently bleached. The frame is drawn up by the crane, and the cotton removed from the rails on which it hangs, and being rinsed in clean water, is carried out and spread on the grass in the fields, to be subjected to the sun and air, by which the bleaching is completed. It is not the business of the present article to enter into the theory or chemical principles of this process, which will be found under the article BLEACHING.

After the hanks are returned bleached, the yarn is found to be much lighter, so that it will generally be two numbers higher: thus, cotton of N^o 48 hanks to the pound being sent to bleach, will return so much diminished in weight, as to require 50 of the hanks to weigh a pound. But this rule is not so exact as is requisite; the thread must therefore be reeled over again, weighed, and packed. A great proportion of the sewing cotton is wound into balls of a very beautiful appearance by a curious winding machine. As a preparation to this winding, the thread must be wound off the hanks in which it was bleached to large bobbins. This is done in a machine provided with several spindles, like the doubling machine, upon which bobbins are stuck, and the thread wound on them from the hanks, when they are extended or stretched out between two pul-

MANUFACTURE OF COTTON.

les, or small reels, on which the hank revolves in the manner of an endless band. These bobbins are taken to the

Ball Winding Machine, see *figs. 3. and 4. of Plate XII.* the former being a plan of the acting parts, and the latter an elevation of the whole machine on a smaller scale. In *fig. 4.* A is the bobbin from the winding machine, which is stuck upon a pin projecting upwards from the bench, and a small lead weight is laid upon the top of the bobbin, to load it, and cause such a friction as will make the thread wind with a proper tension upon the ball. The principal part of the machine is a spindle B, which is perforated through its length, and receives the thread: it runs, in bearings, at the top of two standards *a, b,* and at the extreme end of the spindle, beyond the front standard, a flyer or branch, D, is fixed, and the end, *d,* of it therefore describes a circle when the spindle, B, turns round by the endless band which surrounds the pulley E, and gives it motion from the mill. The spindle has an endless screw cut upon it, turning a wheel, G, at the upper end of the vertical spindle F, which, at the lower end, has an universal joint, *e,* connecting it with an inclined spindle H: this, at the lower end, has a small bevelled wheel, *h,* turning another, *f,* on a small vertical axis, carrying, at the upper end, an universal joint, which communicates motion to an inclined spindle I, and this, by another similar joint at *i,* connects with a vertical axis *r,* which has a pinion, *k,* turning a wheel *l,* upon whose spindle, *m,* the thread is lapped to form the ball; as shewn in *fig. 3:* the spindle, *m,* is supported by a piece of metal, K, formed like the letter L, and moveable on a centre pin *n,* which is situated exactly in a line with the short vertical axis of the wheel *f:* M is a circular plate, on which the piece, K, rests, when turned about on its centre pin *n,* and N is the handle by which it is turned about at pleasure upon it. The two spindles, B and *m,* are, as shewn in *fig. 4,* on the same level, but are capable, as shewn in *fig. 3,* of being set at any angle to each other by inclining *m* on its centre pin *n,* and this being in the line of the spindle of *f,* the motion does not tend to lengthen or shorten the spindles I and *r;* but they always convey the motion, communicated from the spindle, B, by means of the axes F H I and *r,* to *m,* by the several wheels G, *h, f, k,* and *l,* which have been described: they are so apportioned, that the spindle, *m,* turns only once for 48, 60, or 72 revolutions of the spindle B. These different numbers are used in different machines, and the appearance of the ball they will wind materially depends upon this circumstance.

To explain its operation, suppose the spindle, *m,* inclined to B, as in *fig. 3,* the rapid motion of the spindle, and its flyer D, (over the point, *d,* of which the thread is conducted) laps the thread round the spindle, *m,* in an oblique direction. At first, the ball thus formed has no regular figure, but as the thread accumulates and forms a cone, the lapping of the thread in a regular order begins and continues, as in *fig. 3;* here it is seen, that the motion of the flyer will lap the thread obliquely upon the ball from one end to the other, as the figure shews; but at every succeeding revolution of the flyer, the ball itself has made $\frac{1}{48}, \frac{1}{60}, \frac{1}{72}$ part of a revolution upon its own axis *m,* according to the proportion of the wheel-work, and thus the thread is not always disposed on the same oblique line, but on another parallel to it, and removed a small distance from the former. Now it is plain, that the thread on the underside of the ball must be inclined in a contrary direction to that lapped on the upper side; therefore, when the ball is looked at, the oblique threads of every alternate layer cross each other, in the manner of the figure. This will, however, be much

more readily understood from an inspection of a ball of this kind, than from any verbal description. The length of the ball depends upon the angle which the spindle, *m,* makes with the spindle B; it can, therefore, by shifting the handle N, be wound off of any required figure; but the most general method is, when about one half the size of the ball is wound, to give the spindle a greater degree of obliquity: this occasions the ball to wind longer from that period, as well as a greater diameter: the consequence is, that when the ball is finished, on looking at the end of it a circular hollow is seen in it, as though it had been turned in a lathe, and sometimes a thin-membrane, consisting of about two or three layers of thread, is extended nearly across the end, leaving the hollow beneath, which can be seen into from a small hole in the end. This membrane is made by setting the handle, N, at the greatest angle it will make, the thread then not only lays over the whole surface of the ball, but is stretched partly across the end of it; and the intersection of a great number of these forms a transparent membrane, which has a circular hole in the centre. After laying this layer two or three times over, the handle, N, is returned to its original angle, and winds the ball as at first.

The bench or table R R, on which the machine stands, is made long enough to contain fourteen spindles, all placed in one row; and a throfile cylinder, running along under the bench, gives motion to them all at once. Two children attend the whole fourteen, which they can readily do, having only to lap the thread, at the beginning, upon the spindle *m,* and then, when the ball has arrived at a certain size, to turn the handle N; but the period or quantity of this alteration is not of any great importance, as it only influences the figure of the ball, and, as we before described, those fancy ornaments within the hollow end: these may, by great attention in frequently and artfully shifting the handle N, be made very delicate and beautiful. The machine we have just described was made after a model of a machine invented by Mr. Brunell, who first devised the means of connecting the spindles, B and *m,* by wheel-work. The machines, before this, were turned by endless bands, from the principal cylinder which gave motion to the whole. The defect of this method was, that the relative diameters of the wheels could not be so exactly proportioned, as to produce one turn of *m* for exactly forty-eight, &c. of B; that the threads of the successive layers would lay exactly one over the other, because the least variation in this respect would greatly injure the effect of the ball. But in the machine before us, the motions are so accurate, that, on inspecting the ball, it appears honey-combed, or consisting of regular cells, which gradually diminish in size as they approach the centre: the partitions between these cells are only one thread in thickness, but consisting of a great number, stretched so exactly over each other, that they form regular plane sides to the interior of the several cells.

We have now presented our readers with all the operations of cotton-spinning; but these operations are conducted on so grand a scale by many manufacturers, that the system of their management, the arrangement of the buildings, the construction of their water-wheels, steam-engines, or other first movers, and many other particulars, are no less admirable, and worthy of description, than the machines themselves. To describe all these curiosities of the cotton trade would fill a volume; but we must content ourselves with describing one plate, which contains drawings of one of the most complete cotton-mills we have ever visited. It is one of the four mills at Belper, in Derbyshire, belonging to Messrs. Strutts, whose very extensive works contain almost every improvement in the cotton trade. The whole of these

MANUFACTURE OF COTTON.

these mills is built fire-proof, being without any timber beams in the floors, or much wood work of large size in any of the machines, which makes them very secure from danger by fire.

Fig. 1. of *Plate XIV.* is a longitudinal section of the whole mill, shewing all the floors, and all the machines upon them, at one view. *Fig. 2.* is a section, across the length of the former; and *fig. 3.* is a similar cross section of the mill, and, at the same time, a longitudinal section of the wing, which extends from the centre of the mill, at right angles, to its length; so that the plan of the mill is of the figure of the letter T. We will first explain the manner of building fire-proof mills without timber, which has been adopted by Messrs. Strutt in their very extensive works.

The side walls A A, B B, and the end walls C C, D D, are built up as usual, and with the usual doors and windows in them; the several floors, E, F, G, H, I, K, are composed of brick arches, as shewn in the figures. In *fig. 1.* these arches are shewn cut across the span; and in *fig. 2.* they are shewn cut through the crown, parallel to the axis. These arches have a very small rise, and their span is nine feet from one to the next. The abutments, or springings of the arches, are supported by iron columns, *a, a*, as shewn in the figures, which are erected, one upon another, in the several floors, through the whole height of the mill. They are connected by cast-iron beams or girders, *b, b*, shewn in *fig. 2.*, one of which extends from the top of every column to the next, and forms a support or springing for the arches. In an opposite direction to these girders, every pair of the columns, *a, a*, are tied together, across the arch, by a wrought iron bar, which has an eye at each end, to be hooked over the tops of the columns, and keep them tied together, resisting the lateral thrust of the arch, and preventing the columns from being thrust asunder from each other, as they would otherwise be. Thus, though every floor is formed of a system of arches, like a bridge, as shewn in *fig. 1.*, yet the lateral strain of each is supported by iron ties; so that each arch stands by its own supports, independent of its neighbours. The arches are of only one brick thickness, and are covered over at top by a floor of paving bricks, to make a flat surface above, the haunches of the arches being filled up by rubbish. The iron ties across the arches are concealed within the brick-work of the arch, so that they do not appear; the ceilings of the rooms, therefore, consist of regular arches, which have a very good appearance, and make the most firm and solid floors above that can be imagined. The roof is of cast-iron, as shewn in *fig. 2.*, where the two columns, *d, d*, are a continuation of the columns, *a, a*, in the lower floors; and a cross or girder beam, *e*, which connects them, is also a support of the cast-iron principals, *f, f*, of the roof; and *g, g*, are further stays, proceeding from the iron girders uniting the columns of the ceiling, *k*, beneath: the space between the two columns, *d, d*, in the roof, forms a small room, which is used as a school-room for the work-people on Sundays. The desks and forms are shewn in the figure.

The mill contains fifteen arches in length, as shewn in *fig. 1.* between the walls C C, D D, which are the end walls of the mills. Besides these is another wall, L, to which the floors are continued by two additional arches, added beyond the end wall, C, of the mill. This space forms a small room on each floor, which is occupied by the counting-house, stair-case, and the stove, which warms the mill in winter; and also a crane of a peculiar construction, for drawing up the goods to the machines on the several floors.

The space of the mill, therefore, between the walls C

and D, is appropriated to the machinery, as is also the wing, which consists of six arches, as shewn in *fig. 3.* projecting from the middle of the mill, perpendicular to its length.

The width both of the mill and the wing is, as shewn in *fig. 3.* composed of three lengths of arches, having three iron girders that they rise from, and two columns to support them. The arches in the ground-floor, or cave of the mill, are supported by very strong piers, *m*, instead of iron columns. These piers are founded very firmly in the earth, and every caution taken to prevent them subsiding, or settling under the great weight they have to carry. The columns of the first floor are erected immediately upon the top of these piers: on the top of these columns are those for the second floor; the third surmount these, and so on to the top of the mill: the columns being thus erected, one upon another for the whole height of the mill, forms the staunchest building that can be imagined.

We shall now proceed to describe the machinery of the mill. The whole motion is taken from the great water-wheel M, situated underneath the wing, in the cave, or lowest room of the mill; and as it is of so great a size, namely, 18 feet diameter, and 23 feet long, that no cast-iron girder could be thrown across it strong enough to support the arches for the wing above it, a strong stone arch, N, is thrown across from the wall *b*, which is built up at one end of the water-wheel, to the wall, A, of the mill, which is at the other end of the mill; and to resist the thrust of this arch, two strong iron bolts, *v*, are extended across it, and render it as strong as possible; so that the iron columns of the wing over it may be raised upon it as safely as they could upon foundation piers, *m*, like the others. But as a precaution against overloading the walls, *b* and A, which, as they settled in the least, the arches of the wing immediately over the water-wheel are built, instead of solid brick, with small pots like garden pots, so that they are light, but sufficiently strong to bear any thing which is ever required to be loaded upon them. These small pots are also used to build the arched floor, K, of the roof; that it may be light, and as it has nothing to bear but the school room, they are sufficiently strong to make the floor.

The great water-wheel has a cog-wheel, *o*, upon the end of its shaft, which turns a pinion, *p*, on a strong shaft, that carries a wheel *q*, and thus turns a pinion on a third shaft, *r*: this, at the end, has a bevelled wheel, which gives motion to a vertical shaft, *s*, proceeding up to the top of the mill, and turning the machinery in the several floors. The bevelled wheel on the shaft, *r*, also drives a horizontal shaft, *t*, extending the whole length of the mill, and having upon it, just beneath every arch, a bevelled wheel, turning another on a vertical spindle, which rises up through the two floors D and G. These are the main spindles of the spinning frames, and the great frames are fixed upon them. The frames are all shewn endways in *fig. 1.*; but in *fig. 3.* on the floor F, a pair of frames are shewn in front, as they stand side by side, and the floor, G, over it has just the same, as has also the wing, though not put in the drawing; but these last are turned by a bevelled wheel, *v*, *fig. 1.* on the shaft *s*, in the floor G, which turns a horizontal shaft, *v*, *fig. 3.* extending the whole length of the wing, and turning the spindles of the several frames as it passes over them. The two lowest floors, F, G, which are appropriated to the spinning frames, contain 28 frames on each floor, 56 and 12 more in the two floors of the wing, in all containing 4236 spindles, a considerable proportion of which are, however, employed in spinning the hard twill. The two next floors, *viz.* the

MANUFACTURE OF COTTON.

the 3d, H, and the 4th, I, are occupied in the body of the mill with carding machines, which stand in three rows: they are turned by straps from a horizontal shaft, extending the whole length of the mill, over the machines. In *fig. 1.* they are shewn endways, and *fig. 3.* shews them in front of the floor H, while that above it is just the same, though not drawn: in all these two floors are 64 breaking cards, and 72 finishers. The same floors, H and I, in the wing, contain 16 drawing frames and four stretching frames or mules, in which the rovings are prepared as described in our account of the different methods of making rovings. The fifth floor, L, contains the reeling, doubling, and twisting machines, &c. as we have described; but the numbers of the different kinds of these last mentioned machines vary in every mill, according to the kind of cotton which is to be spun in it, and that branch of trade its proprietor intended to carry on: if it is for spinning twist for weavers, only reels will be wanted in the fifth floor; or if it is to spin stocking yarn, doubling and twisting machines will be wanted. Indeed these last machines are altered every few years in cotton mills, according as the state of the trade varies from a demand of one article to another.

The space of the mill, between the walls C and L, contains, as before-mentioned, the staircase O, which is of stone, ascending from one floor to the next, and also the crane P P. This is a most ingenious and useful machine, which has been adopted by Messrs. Strutts in all their cotton mills, and it is applicable to many other manufactories. The crane consists of a large square basket, or cradle, four feet six inches square in the bottom, within side, and six feet deep: it is open in front. The bottom is a floor of wood, and the sides wicker or basket work strongly bound with iron straps. This basket or cradle is suspended by a rope in a well P, extending from the top to the bottom of the mill, through all its floors. The cradle exactly fills the well, and is guided by iron sliders in each angle, so that it may be steadily drawn up from one floor to any other by the power of the mill, and stopped or set in motion, either up or down, at pleasure, by pulling two guide ropes, which are always in reach of a little boy who sits at the top of the cradle in a seat made for the purpose. Now the machinery for effecting this is the only difficulty: it is necessary, in such a crane, that the machinery, when call on to draw up the cradle, should move with a regular and equable velocity, without making any shock or jerk when it first starts; that it should stop the instant it is required, otherwise it would be very difficult to set the cradle, with its floor, exactly on a level with any of the floors of the mill, and if not so, it would be very inconvenient for the people to get in or out of it.

The cradle must also be let down by the power of the mill as well as drawn up, because if suffered to run down by its own weight, it would always run down too quick or too slow, and be dangerous and uncertain: it must, at the same time, be so contrived, that the cradle itself will stop the machine if drawn up too high, or let down too low, to prevent its being over-wound and breaking the works. All these conditions are effected, in the most perfect manner, by very ingenious mechanism, which was invented by Mr. H. Strutt, and has been adopted in all his father's mills, rendering these cranes as safe and manageable as possible. The rope suspending the cradle in the well is double, to ensure greater strength, and is conducted over a pulley, or grooved wheel, situated in the roof of the mill. The other end has such a weight suspended from it, as will balance the weight of the cradle, together with half the weight of the usual load the crane is expected to carry. This weight, therefore, draws the rope so tight upon the grooved wheel, that it will, by

turning round one way or the other, elevate or depress the cradle at pleasure, and at the same time the balance weight, which has a small well of its own to work in. The axis of the grooved wheel has a cog-wheel on the end of it, which is turned round by a small pinion fixed on the extremity of an axis on which the mechanism is placed: it consists, first, of a large wheel, like a coach wheel, shewn at *x*, *fig. 1.* fixed on the middle of the axis, and on each side of this are two broad riggers or drums to receive the endless straps, which give the motion against these riggers on the outside of each. A dead pulley or rigger is fitted loosely on the axis, and being exactly the same size as the live riggers or pulleys, the strap can be shifted from one to the other in a moment. The axis is actuated by two endless straps coming from one drawn at *y*, *fig. 1.* which is turned by wheel-work from the shaft in the fifth floor of the mill, as the figure shews. One of these straps is crossed between the two drums, and the other is not, so that the motion of the two dead pulleys on which these straps act are always in contrary directions to each other, whilst the axis on which they run is stationary. The two straps are guided by passing through eyes attached to a side rail of a square frame, which includes the axis with both its riggers and great wheel, and is suspended from the top of the machine by four pendulous rods, so that it has free motion to swing backwards and forwards in a direction parallel to the length of the axis of the pulleys, which motion is communicated by a crank formed on a spindle, having a grooved wheel on the end of it. An endless rope passes over this wheel, and then descends to the bottom of the well, where it is frained beneath another wheel, so that the two sides of this rope are always in reach of the boy before-mentioned, who rides in a seat at the top of the cradle, giving him the means of turning the wheel and crank either way about, for by pulling down one of these guide ropes, he turns the wheel and crank, and draws the suspended frame one way, or by pulling down the other guide rope it is drawn the other. The consequence of these movements is, that the endless straps are shifted both together on one or other of their live pulleys, whilst the other strap will be shifted upon the opposite dead pulley; consequently, the strap which is upon the live pulley turns the axis round one way or the other, drawing the cradle up or down, as it happens to be the crossed strap, or the opposite one, which is shifted on the live pulley, fixed on the axis at either side of the great wheel, which we first compared to a coach wheel. This is, in reality, a brake wheel, having a broad strap surrounding the lower half of it, both ends of which are conducted over two pulleys, and levers with heavy weights draw down the ends, so that it has a constant tendency to press upwards beneath the wheel, to break, or cause such a friction upon it, as will stop its motion, when the two endless straps are shifted upon their dead pulleys; but when the swinging frame is shifted either way, by the boy pulling down one of the guide ropes, which go down to the bottom of the well, and either of the straps are thus shifted upon the live pulleys, the frame seizes the tail of a bent lever on each side the wheel, and relieves the weights which draw the strap against the wheel, and it hangs quite slack beneath the wheel, with a considerable space all round, so that its motion is quite free, and only under the influence of that strap which, being upon one of the live pulleys, gives it motion in either direction. The crank before-mentioned for shifting the swinging frame is so contrived, that it always has a tendency, by means of a weight, to assume such a position, that it will direct the swinging frame, and the straps, both upon the dead pulleys and the brake strap, being at the same time in contact with the lower half of the wheel, the cradle will stand

MANUFACTURE OF COTTON.

stand still; but when the crank, by pulling one of the guide ropes which go down to the bottom of the well, is turned to shift the endless straps either way, and consequently put the cradle in motion, the crank drops into a kind of hitch, or catch, which holds it in that position, but not so fast but that it can be relieved in a moment by snatching the guide or rope, and if left to itself it then assumes that position in which the crane will stand still. By this means the crane is in no danger of any accident, as it is always under the action of one or other of the endless straps, which cause it to ascend or descend, or it is under the brake strap, which makes it stand still, and the great advantage of all these movements are, that they act so softly, without any sudden jerks or snatches in changing from one state to another. The well has a gate fixed up at every floor to prevent people falling down into the mill, and if any person, on the fifth floor for instance, wishes to descend to the third, he goes to the gate and calls the boy, who, with the cradle, is perhaps below, to come to No. 5, which he does by snatching that guide rope which makes the crane draw up, when he sees the floor of the basket come exactly opposite the floor of the mill No. 5. He snatches the opposite rope; this jerks the crank out of its hitch, and it shifts the straps and brake, stopping the cradle in an instant, so that it is seldom half an inch out of level with the floor. The person who wishes to go down can now open the gate, which he could not do before, because the latch of the gate is lifted up by the cradle, when its floor is level with the floor of the gate, and stepping into the cradle he mentions the floor he wishes to go to, and the boy pulls down that directing rope which lets him down, and stops it at the floor he wishes, by snatching the other rope; but if he should pull the wrong, no harm can ensue, because the brake will always act to stop the machine, if the straps do not act to move it. The bobbins of the spinning frame, and the cops of the mule, are set up in little frames mounted on wheels, and thus wheeled along by little children to the crane, and drawn up or let down as required, without any hard labour; in fact the stairs are seldom used except for the people to go up and down when they begin and leave off work.

The stove which warms all the mill is situated down in the cave beneath the staircase: it is very ingeniously contrived with an iron cockle, or inverted cubical vessel, beneath which a fire is made, and the smoke escapes by a flue behind into a chimney. The air is then brought in a current to strike upon the external surface of this cockle, and being thus warmed, rises up through flues into every floor of the building, where it is admitted in any quantity at pleasure by registers, which are regulated to produce an agreeable warmth, but as the warm air escapes again with a draught through a proper ventilator, there is nothing of closeness connected with it.

Our limits will not permit us to describe more of the ingenious contrivances with which Messrs. Strutt's extensive mills at Belper abound, neither could the reader form a good idea of them without additional plates, and we have already exceeded our proposed number. Messrs. Strutt very liberally permitted the writer of this article to visit their works, for the purpose of composing it, to take drawings of the principal machines, which are of the very best construction of any in the cotton trade. These would have appeared here; but that the first six plates of our series were drawn and engraved some years ago, being intended for the article COTTON, at a time when the machinery was not brought to that perfection, in point of construction, that it is now. Indeed, the mechanical ingenuity called forth in

the whole manufacture of cotton, is beyond the conception of those who have not visited the countries where it is carried on. The tools and implements employed in constructing the different machines are very curious; for as there are such immense numbers of each part of every machine to be made, it becomes, in the same manner as with the clock-maker, worth the machine-maker's trouble to construct complicated tools and engines to expedite the manufacture of the parts; thus cutting engines for forming the teeth of the numerous wheels, see *Cutting Engine*. And here we would remark, that Mr. George Gilpin of Sheffield has, since the printing of that article, invented a method of cutting wheels from solid cast iron, with as much accuracy and as good a finish as brass wheels have hitherto been cut, making a very great saving in the expence of brass for a large mill, and much more durable when done. Card wires are manufactured in a very extensive scale in Yorkshire, and many very curious machines have been invented to diminish the labour of cutting and bending the wire teeth, and pricking the leathers for them: but a patent has been lately taken out, by Mr. J. C. Dyer, for a machine which cuts and bends the wires, pricks the leathers, and puts them in all at one operation, and with such rapidity, that it completes four *per* second. It is one of the most ingenious and perfect machines we ever met with, and it will prick and stick any sort or size of teeth, by altering adjustments introduced for that purpose. Drawings and a full description of this curious machine are lodged in the patent office by the patentee, who brought over the invention from America, where it has been some time in constant use. Curious lathes for turning spindles, and various other circular work, are used in the workshops of the cotton mills and fluting machines, for cutting the flutes in the lengths of the rollers of the drawing and spinning frames: in short, such works as Messrs. Strutt's at Belper, Mr. Arkwright at Crauford, in Derbyshire, Messrs. Phillips and Lees at Manchester, Mr. Peeles' and many others, are schools for mechanics in almost every department of the science; and good ones too, as the cotton manufacturers in general are convinced, that it is their interest to attend to every minutia in the construction of their machines, which may render them more durable or their operations more perfect. Among these improvements we may mention, what is becoming very general, *viz.* the addition of governors, or regulating balls, to the water-wheel, which turn the cotton mills, as they always keep it moving at the same speed, without which all the machines in the mill act irregularly, and it must happen that the velocity of the common water-wheel varies, when any number of machines are stopped, or cast in motion; but the regulated water-wheel always adapts its draught of water to the work it has to perform, preserving an uniform velocity in itself and all the machines it turns. This is brought to such perfection, that many such mills have a clock turned by the mill; close to it another clock, regulated in the usual manner by a pendulum, and the motion of the mill is so regular, that these two clocks will never vary more than two or three minutes. Both are made with dials and hands exactly alike, but one has a title on the dial, *mill* time, and the other, *clock* time. We shall take an opportunity of explaining a regulated water-wheel, under WATER-WHEEL.

We shall here close this article, though we have only gone through the detail of cotton-spinning, because the subsequent processes of weaving cotton-thread into cloth, dressing, finishing, printing, &c., have been or will be explained

plained under the following several heads; viz. for explanations of the weaving processes, see DRAUGHT of looms, or CORDING, DRAW-LOOM, DRAFER, DIMITY, DORSOCK. Though the three last are rather linen than cotton, still the same processes apply in part to the weaving of cotton goods; see also FUSTIAN, and lastly, WEAVING. For the dressing of cloth after weaving, see CALENDAR, or rather PRINTING of Calico, which precedes the calendar, except for some particular goods; and as a part of calico-printing see DIPPING; also BLEACHING, DYEING, DISCHARGING, and WASHING-WHEELS. And, as we have before mentioned, a full account of the wonderful rise and progress of the cotton manufacture, which is wholly founded upon the improvements in the machinery for spinning, will be found under COTTON. Under the head of SPINNING, we shall describe those variations of the cotton machines, which have been made to adapt them to the spinning of flax, wool, and worsted.

MANUFACTURERS. Persons enticing artificers into foreign countries incur the penalty of 500*l.* and twelve months imprisonment, for the first offence, for each person so seduced, and 1000*l.* and two years imprisonment, for the second offence. (23 Geo. II. c. 13.) And such artificers not returning within six months after warning, shall be deemed aliens, forfeit all their lands and goods, and be incapable of any legacy or gift. (5 Geo. I. c. 27.) By 22 Geo. III. c. 60. if any person shall contract with, or endeavour to persuade any artificer concerned in printing calicoes, cottons, muslins, or linens, or preparing any tools for such manufactory, to go out of the kingdom, he shall forfeit 500*l.* and be imprisoned for twelve months; for a second offence, 1000*l.* and be imprisoned for two years.

MANUGASTA, in *Geography*, a town of South America, in the province of Tucuman; 20 miles S. of St. Yago el Eiteros.

MANULCA, in *Antiquity*, that part of the catapulta to which the cord used in working it was fixed.

MANULEA, in *Botany*, so named, as it should seem, from *manulea*, a covering for the hand, in allusion to the form of the corolla, the four segments of whose limb pointing one way, and the fifth separate from them, suggest the idea of a glove, at least in *Manulea Cheiranthus*. Linnæus, who gave this name, scarcely ever deigned to give any explanation of the names he contrived, and we offer the above as a conjecture only. Professor Martyn leaves it unexplained. Linn. Mant. 12. Schreb. 416. Willd. Sp. Pl. v. 3. 327. Mart. Mill. Dict. v. 3. Thunb. Prod. 100. Juss. 100. Lamarck Illustr. t. 520. Gært. t. 55. (Nemia; Berg. Cap. 160.) Gen. Ch. *Cal.* Perianth inferior, in five deep, linear, erect, equal, permanent segments. *Cor.* of one petal, irregular; tube cylindrical, contracted at the mouth; limb spreading, in five deep awl-shaped segments, the four uppermost of which are most connected at their base, the lower one being reflexed. *Stam.* Filaments four, very short; anthers of the upper two in the mouth of the corolla, those of the two lower rather oblong, within the tube. *Pist.* Germen superior, roundish; style thread-shaped, the length of the lower stamens; stigma simple. *Peric.* Capsule ovate, the length of the calyx, with two cells and two valves, which last when ripe are half cloven; partition double, formed of the inflexed margins of the valves. *Seeds* numerous, small, affixed to an oblong, compressed, central column.

Eff. Ch. Calyx inferior, in five deep segments. Limb of the corolla in five deep awl-shaped segments, the upper four of which are most connected. Capsule of two cells, with many seeds.

Obs. The above characters are taken from the original species, *M. Cheiranthus* above-mentioned, but they by no means agree, at least in the limb of the corolla, with the generality of those subsequently referred to this genus in the *Supplementum* and elsewhere. Bergius gives as the essential character of his *Nemia*, which includes *M. Cheiranthus* and *rubra* of Linnæus, that the two upper anthers are roundish, the two lower oblong. This however is probably variable, and certainly not very important. Thunberg indicates no generic character, but enumerates a great number of species, 28, in his *Prodromus Plantarum Capensium*, four of which have entire, 23 toothed or serrated, and one pinnatifid leaves. Willdenow admits but 17 in all, not having, when he wrote, seen the second part of Thunberg's work.—The chief difficulties are found in distinguishing between *Manulea*, *Erinus* and *Buchnera*. Ventenat in his *Jard. de la Malmaison*, 15, suggests that the two former are most nearly allied, and differ only in the lobes of the corolla of *Erinus* being more or less notched or cloven, while those of the genus before us are entire. *Buchnera*, according to this writer, differs so essentially from both as to belong to a distinct natural order, the *Pedicularis* of Jussieu, as having the partition of its fruit, contrary to the valves; whereas the other two genera, having it parallel, belong to the *Scrophulariæ* of that author. As the matter is so obscure, and the plants so little known, we shall take a view of all those in Willdenow, giving what illustration is possible from original specimens, and adding what we can that has escaped him.

1. *M. Cheiranthus*. Hand-flowered Manulea. Linn. Mant. 88. Willd. n. 1. (*Lobelia Cheiranthus*; Linn. Sp. Pl. 1319. *Nemia Cheiranthus*; Berg. Cap. 160. *Cheiranthus africana*, flore luteo; Commel. Hort. v. 2. 83. t. 42.)—Leaves obovate-oblong, serrated, hairy. Stems nearly leafless, somewhat racemose. Segments of the corolla taper-pointed.—Native of the Cape of Good Hope, as are all the following species. Commelin cultivated it at Amsterdam in 1697, and named it *Cheiranthus*, from the resemblance of the flower to a hand, an etymology that confirms our explanation of the Linnæan generic name above. The root is annual, spindle-shaped. Stems about a span high, erect or ascending, nearly simple, almost leafless, each terminating in a simple, elongated, bracteated cluster, of numerous yellow flowers, whose form is described in the generic character. The leaves are almost all radical, stalked, obovate or oblong, strongly serrated, more or less hairy, paler beneath. The herbage, calyx, bractæas, and even the outside of the corolla, are besprinkled with silvery dots or granulations. The capsule is elliptical and smooth, its partition formed by the inflexed margins of the valves, and so far parallel thereto.

2. *M. corymbosa*. Corymbose Manulea. Linn. Suppl. 286. Thunb. Prod. 102. Willd. n. 2.—“Leaves obovate, toothed, smooth. Flowers in level-topped, somewhat umbellate, clusters.”—We know nothing of this species but the above characters, given by Thunberg and the younger Linnæus. The stem is said to be naked.

3. *M. altissima*. Tall Manulea. Linn. Suppl. 286. Thunb. Prod. 102. Willd. n. 3.—Leaves radical, lanceolate, somewhat toothed, hairy. Stem elongated, almost naked. Spike ovate-oblong. Lobes of the corolla rounded.—The leaves are all radical, about four inches long, lanceolate, tapering down into a footstalk; their edges unequally

equally toothed; their surface clothed with short glandular white hairs. *Stem* two feet high, erect, hairy in the same manner, scarcely at all branched, terminating in a dense, rather corymbose, *spike*, of numerous, large, and apparently handsome, *flowers*, the segments of whose corolla are unequal, spreading horizontally, of a rounded somewhat kidney-like shape; the mouth closed. *Calyx* hairy, divided to the very base. *Capsule* of the structure proper to the genus.

4. *M. plantaginea*. Plantain-like Manulea. Thunb. Prod. 101. (*M. Plantaginis*; Linn. Suppl. 286. Willd. n. 5.)—Leaves ovate, obtuse, stalked, entire or toothed, smooth. Stems diffuse, nearly naked. Spikes ovate. Bractees obovate, longer than the flowers.—*Root* long, fibrous, apparently annual. *Stems* three or four, decumbent, divaricated, about two inches long, simple, almost leafless, hairy. *Leaves* not unlike those of a daisy, ovate, obtuse, smooth, fleshy, occasionally toothed, measuring, with their *footstalk*, rather above an inch in length. *Spikes* mostly solitary, short, round and dense, of many small *flowers*, separated by obovate, obtuse *bractees*, twice their own length, whose base only is hairy. *Calyx* bell-shaped, hairy, not very deeply divided. Segments of the *corolla* rounded, and some of them, if we mistake not, cloven, in which case this plant becomes an *Erinus*.

5. *M. linifolia*. Flax-leaved Manulea. Thunb. Prod. 100.—“Leaves linear, nearly entire, rough with minute hairs.”—We received from Kew garden in 1791, specimens by the name of *Manulea*, which answer exactly to the above characters of Thunberg, of whose plant we have no further information, it not being described by Linnæus or Willdenow. Our’s has a slender, branched, leafy, nearly smooth *stem*. The *leaves* are opposite, stalked, an inch and half long, about a line broad, bluntish, rough with minute glandular pubescence; their margin occasionally toothed; their base tapering into a slender *footstalk*. *Flowers* numerous, in loose, compound, terminal clusters, with small oblong *bractees*. *Calyx* small, obtuse, smooth. *Corolla* slender, above half an inch long, its tube glandular in the upper part, its limb of a rich deep yellow, in five oblong, obtuse segments, whose edges are reflexed, and one of which seems more spreading than the rest, as in the first species.—Can what we describe be *Buchnera viscosa*, Ait. Hort. Kew. ed. 1. v. 2. 357? L’Heritier’s figure has never appeared.

6. *M. pinnatifida*. Pinnatifid Manulea. Linn. Suppl. 286. Thunb. Prod. 102. Willd. n. 4.—“Leaves ovate, pinnatifid; their segments toothed.”—This we have not met with.

7. *M. capitata*. Capitata Manulea. Linn. Suppl. 286. Thunb. Prod. 101. Willd. n. 6.—“Leaves ovate, ferrated, villose. Flowers in globose heads. Branches diffuse.”—Such is the Linnæan character, but Thunberg says the *leaves* are oblong and smooth. It seems next akin to *M. plantaginea*.

8. *M. antirrhinoides*. Snap-dragon Manulea. Linn. Suppl. 286. Thunb. Prod. 101? Willd. n. 7.—“Leaves ovate, toothed, smooth. Flowers alternate.”—Here again is some contrariety between Linnæus and Thunberg. The latter, who gathered the plant, defines it “leaves ovato-lanceolate, ferrated, villose. Heads of flowers globose. Stem erect.”—Linnæus says it looks like an *Antirrhinum*. We have in vain attempted to determine it by his herbarium.

9. *M. thyrsoiflora*. Crowded-flowered Manulea. Linn. Suppl. 286. Thunb. Prod. 102. Willd. n. 8.—“Leaves obovate, downy, toothed. Corymb terminal, elongated, compound.”—Thunberg describes the *leaves* as crenate, the

flowers panicled. We have what seems to be this species, gathered by Sparrmann in shady places at the Cape. The *stem* is somewhat shrubby, and very much branched, hairy. *Leaves* opposite, hairy, strongly toothed. *Inflorescence* at first corymbose, afterwards becoming more loose and panicled. *Calyx* hairy, with long slender divisions, not quite separate to the base. Segments of the *corolla* obovate.

10. *M. argentea*. Silvery Manulea. Linn. Suppl. 286. Thunb. Prod. 102. Willd. n. 9.—Leaves alternate, obovate, wedge-shaped, ferrated, besprinkled with silvery dots. Flower-stalks axillary, single-flowered, longer than the leaves.—Thunberg’s own specimen, given to Linnæus, here leaves no doubt on our minds, though their definitions of it a little vary. The *stem* is woody, with numerous crowded leafy branches. *Leaves* stalked, small, alternate, with little axillary tufts of still smaller ones; their form obovate or roundish, strongly ferrated, wedge-shaped and entire at the base; the under side, more especially, clothed with glandular silvery dots, as is also the deeply-divided *calyx*. Segments of the *corolla* rounded. The *flower-stalks* are solitary, axillary, simple, smooth, about an inch long, much exceeding the leaves. *Capsule* proper to the genus. The plant turns black in drying.

11. *M. oppositiflora*. Opposite-flowered Manulea. Ventenat. Malmail. t. 15.—Shrubby, downy. Leaves opposite, ovate, deeply ferrated. Flower-stalks axillary, single-flowered, the length of the leaves.—M. Ventenat describes this as a native of the Cape, flowering profusely during the summer and autumn. It has the shrubby habit and aspect of the last, but the opposite *leaves* and *flowers* clearly distinguish it. If *Buchnera pedunculata*, Andr. Repos. t. 84. be, as Ventenat says, generically distinct, and even essentially different in its capsule, from these two species, it must be allowed their habit is too similar to make such a difference credible in all the force he allows it.

Buchnera aethiopica and *capensis* of Linnæus if, as Thunberg now makes them, species of *Manulea*, should follow here, the former being nearly akin in habit to the two or three last described. But as habit seems treacherous with regard to these plants, we dare not decide. See BUCHNERA.

12. *M. tomentosa*. Woolly Manulea. Linn. Mant. 420. Willd. n. 10. Jacq. Ic. Rar. t. 498. Curt. Mag. t. 322. Thunb. Prod. 101. (Selago tomentosa; Linn. Sp. Pl. 877.)—Leaves obovate, downy, bluntly toothed. Stem leafy. Cluster compound, terminal, many-flowered.—Mr. Masson is said in the Hort. Kew. to have introduced this species into the gardens of Britain in 1774. It is we believe naturally shrubby and perennial. The *branches* are round, leafy, and they, as well as the foliage, *inflorescence*, and even the outside of the flowers, are clothed with dense hoary pubescence. *Leaves* mostly opposite, an inch or more in length, obovate, very obtuse, unequally and bluntly toothed. *Flowers* very numerous, in a dense, compound, hoary cluster, produced from May to November, having, according to Mr. Curtis, “a singular but unpleasant smell, not perceptible at a distance.” The outside of the *corolla* is pale yellow, as is the upper side of the limb when first expanded, but the latter gradually assumes a deeper and deeper orange. There is a great affinity between these flowers and those of our *M. linifolia*, n. 5.

13. *M. rubra*. Red Manulea. Linn. Suppl. 286. Thunb. Prod. 102. Willd. n. 11. (*Nemia rubra*; Berg. Cap. 161.)—Leaves lanceolate, toothed, villous. Cluster lax. Flowers nearly sessile.—Linnæus had no specimen of this. Bergius describes it with an herbaceous, round, nearly

smooth stem. Upper leaves, (or bractes,) linear, toothed, rough, sessile; the lower he had not seen. Cluster terminal, very long and slender, its branches alternate, distant and erect, the flowers nearly sessile. Calyx fringed. Tube of the corolla long, slender, pale red, thickened and hairy upwards; segments of the limb linear-ovate, obtuse, hairy beneath, spreading, nearly equal, revolute in the margin, deep scarlet.

14. *M. capillaris*. Capillary Manulea. Linn. Suppl. 285. Thunb. Prod. 101. Willd. n. 12.—“Stem-leaves obovate, smooth; those of the branches linear. Spikes ovate.” Linn. Thunb.

15. *M. cuneifolia*. Wedge-leaved Manulea. Linn. Suppl. 285. Thunb. Prod. 101. Willd. n. 13.—“Leaves elliptic-ovate, toothed, nearly smooth. Spikes at length oblong. Calyx fringed.—The stem is shrubby, much branched, leafy, round and downy. Leaves nearly opposite, stalked, about half an inch long, ovate, obtuse, with coarse blunt serratures; both sides occasionally slightly hairy, often smooth. Spikes terminal, solitary; at first dense and almost capitate, with a linear, obtuse, fringed bractea to each flower, longer than the flower itself. Segments of the calyx very deep, linear, obtuse, fringed with soft hairs. As the fruit advances, the spike becomes very long. The lobes of the corolla are rounded, obtuse and entire. Capsule elliptical, narrow, obtuse, with a strong furrow at each side.

16. *M. cerulea*. Blue Manulea. Linn. Suppl. 285. Thunb. Prod. 101? Willd. n. 14.—“Leaves linear, opposite, downy, toothed. Flowers racemose.” Linn.—Thunberg defines the leaves as lanceolate, the flowers axillary and solitary. We have seen no specimen.

17. *M. heterophylla*. Various-leaved Manulea. Linn. Suppl. 285. Thunb. Prod. 101. Willd. n. 15.—“Leaves linear, scattered, villose, entire or toothed.” Linn.—Thunberg says “lower leaves ovate, somewhat toothed, villous; upper linear entire. Heads of flowers globose.” We know no more of this than of the last.

18. *M. integrifolia*. Entire-leaved Manulea. Linn. Suppl. 285. Thunb. Prod. 100. Willd. n. 16.—“Leaves opposite, ovate, nearly entire, smooth. Flower-stalks axillary, single-flowered, the length of the leaves.—This is perhaps next akin to our tenth and eleventh species, though essentially different in its leaves, being at most but slightly serrated. They greatly resemble those of *Thymus Acinos*, and the species might well have been named *thymifolia* or *ocymifolia*. The stem is shrubby, round, much branched. Leaves opposite, on short downy footstalks, which embrace the stem; nor are they by any means scattered, as Linnæus defines them. Calyx smooth, its segments long and narrow. Tube of the corolla swelling upwards; segments of the limb rounded, obtuse.

19. *M. microphylla*. Small-leaved Manulea. Linn. Suppl. 285. Thunb. Prod. 100. Willd. n. 17. (Pluk. Phyt. t. 272. f. 7.)—“Leaves densely tufted, ovate, entire, smooth. Flower-stalks lateral, solitary, single-flowered, downy, much longer than the leaves.—Gathered by Sparrmann as well as Thunberg at the Cape. Stem woody, with very numerous branches, along which are arranged crowded dense tufts of innumerable, extremely minute, leaves, each tuft seeming the rudiment of a future branch. The flower-stalks, scattered here and there, are about half an inch long, solitary, simple, ascending, rigid. Segments of the calyx oblong, obtuse, downy, deeply separated. Plukenet perhaps represents the calyx, not the corolla; the latter we have not seen. His figure was justly indicated by Linnæus himself on the specimen, though omitted in the Suppl.

We subjoin the remaining species of Thunberg, without regard to the order in which they ought to come, as we have no means of correctly ascertaining it.

20. *M. revoluta*. Revolute Manulea. Thunb. Prod. 100.—“Leaves linear, entire, revolute in the margin. Flowers axillary.”—This he places next after his *linifolia*; see n. 5.

21. *M. incana*. Hoary Manulea. Ibid. 101.—“Leaves oblong, serrated. Spikes level-topped. Calyx hoary.”—Before *cuneifolia*, n. 15.

22. *M. divaricata*. Spreading Manulea. Ibid.—“Leaves elliptical, toothed. Spike terminal, level-topped.”

23. *M. virgata*. Wand-like Manulea. Ibid.—“Leaves obovate, serrated, villous. Branches paniced. Flowers alternate, remote.”

24. *M. cephalotes*. Great-headed Manulea. Ibid.—“Leaves oblong, unequally serrated, smooth. Flowers somewhat umbellate.”

25. *M. hirta*. Hairy Manulea. Ibid.—“Leaves obovate, doubly serrated, hairy. Flowers axillary, remote.”

26. *M. hispida*. Hispid Manulea. Ibid. 102.—“Leaves ovate, serrated, villous. Stem decumbent.”

27. *M. cordata*. Heart-leaved Manulea. Ibid.—“Leaves heart-shaped, serrated. Stem decumbent, creeping.” S. MANUMISSION, MANUMISSIO, an act whereby a slave, or villain, is set at liberty, or let out of bondage.

The word comes from the Latin *manus*, hand, and *mittere*, to send; quia servus mittebatur extra manum, seu potestatem domini sui.

Some authors define manumission an act by which a lord enfranchises his tenants, who till that time had been his vassals, and in a state of slavery, inconsistent with the sanctity of the Christian faith.

Among the Romans, the manumission of slaves was performed three several ways. 1. When, with his master's consent, a slave had his name entered in the census, or public register, of the citizens. 2. When the slave was led before the prætor, and that magistrate laid his wand, called *vindicta*, on his head. 3. When the master gave the slave his freedom by his testament. Servius Tullus is said to have set on foot the first manner; and P. Valerius Publicola the second. A particular account is given of the third in the Institutes of Justinian.

It was not necessary that the prætor should be on his tribunal to perform the ceremony of manumission: he did it any where, indifferently, in his house, in the street, in going to bathe, &c. He laid the rod on the slave's head, pronouncing these words, “Dico eum liberum esse more Quiritum.” “I declare him a freeman, after the manner of the Romans.” This done, he gave the rod to the licitor, who struck the slave with it on the head, and afterwards, with his hand, on his face and back; and the notary or scribe, entered the name of the new freed-man in the register, with the reasons of his manumission.

The slave had likewise his head shaved, and a cup given him by his master, as a token of freedom. Tertullian adds, that he had then also a third name given him: if this were so, three names were not a token of nobility, but of freedom.

The emperor Constantine ordered the manumissions at Rome to be performed in the churches.

Of manumission there have also been various forms in England. In the time of the Conqueror, villains were manumitted, by the master's delivering them, by the right hand, to the viscount, in full court, shewing them the door, giving them a lance and a sword, and proclaiming them free.

Others

Others were manumitted by charter. There was also an implicit manumission; as when the lord made an obligation for payment of money to the bondman at a certain day; or sued him, where he might enter without suit; and the like.

MANUPELLA, in *Geography*, a town of Naples, in Abruzzo Citra; eight miles S. of Civita de Chieti.

MANURE, in *Agriculture*, that sort of substance or material, whatever its nature may be, that has the property or effect when applied on, and incorporated with a soil, to increase its fertility, and thereby promote the growth of different kinds of plants, such as those of the grain, grafs, and other descriptions.

It may be noticed, that the substances capable of being made use of in this way, are extremely numerous, and of different natures and properties. It has been stated by a late writer, that on account of the changes that are continually taking place among bodies in nature, and the new combinations that are formed in consequence of them, a vast variety of matters are unfolded, elaborated, and prepared for the nourishment and support of vegetables; some of which possess a high degree of fluidity and volatility, as water, various gaseous materials, as oxygen, hydrogen, azote, and carbonic acid, in different states of combination, with other more subtle and elastic fluids, which are principally formed and applied in or upon the soils on which the plants grow and exist; and in larger or smaller proportions, according to the season of the year, the nature of the climate in respect to heat or cold, and the state or condition of the land in regard to its properties; while others exist in a more gross and heavy state of connection with the different materials, and require to be applied and blended with the soils, or spread out upon their surfaces, in order that they may exert their influence in promoting vegetation. But it is these last, as being the chief means of supporting various sorts of plants, as crops, that are considered as manures, though it is plain they must undergo different changes to fit them for the purpose. In addition it is likewise remarked, that in the various substances applied in this way, there are great differences; "some are found to yield the matters which are necessary for the support of plants much more readily, and more abundantly than others, as animal, vegetable, and all such substances as are rich in mucilage, saccharine matter, and calcareous earth, and readily afford carbon, phosphorus, and some aerial fluids, such as have been mentioned; while others that are greatly deficient in all or many of these principles, or do not readily part with them, are found to be of much less utility, when employed in the way of manures." It is supposed that this is "a principal reason why some sorts of manures or substances, when put upon grounds, are so greatly superior to others, used at the same time, and in the same manner and proportion." But besides these there are "other ways in which substances, when applied to soils, may render them more fertile and productive, and contribute to the aid of vegetation. Some, besides furnishing such matters as are suitable for the purpose of promoting the growth of plants, are known to add considerably to the quantity of vegetable and other matters contained in the soils on which they are placed, and thereby provide a more suitable and convenient bed for the reception of the roots of plants; others contribute little in this way, but operate chiefly upon such materials as are contained in them, breaking down their organization or texture, and thus setting at liberty different volatile and other ingredients, by which new compounds are formed, and brought to such states as are the most adapted to the support of vegetable life; others again act principally by producing certain changes and alterations in the constitution or texture of soils, such as rendering them more open

and porous, or more stiff and compact, and by such means bringing them into the most proper conditions for the bearing of different vegetable productions; and there are still others that contribute in all or several of these ways at the same time."

By different inquirers these substances have indeed been conceived to "operate in all the different ways by which vegetation is promoted: by imparting to the soil with which they are mixed the vegetable food which they contain: by communicating to it a power of attracting this food in greater plenty from the air: by enlarging the vegetable pasture: by dissolving the vegetable food which it is already possessed of, and fitting it for entering the roots of plants. Some afford nourishment only; as rape-dust, foot, malt-dust, pigeons' dung, and in general all top or hand-dressings. Others give nourishment, and also add to the soil; as animal dungs, and all rotten animal and vegetable substances. Others again open the soil, and do not nourish in their own nature; as lime, light marles, sand, &c. And lastly, other manures stiffen the soil, and at the same time nourish a little; as clay, clay marles, and earth." Matters of this kind have also been "considered by different agriculturists as simple and compound; as natural and artificial; nutritious and stimulating, or solvents and mucilages; mechanical or chemical; as animal, vegetable, and mineral, &c." All which distinctions may have their use, but are each attended with difficulties, and liable to objections. "Some of them operate in all the ways above-mentioned; and there are probably none that do not operate in more ways than one. It is a fundamental mistake to suppose with Tull, that tillage may be substituted in the place of manure. Manures will indeed be of little avail without it; but although good tillage, by separating the soil, may bring a greater number of nutritious particles within the reach of the crop, yet the soil cannot possibly continue to be so completely divided as it is by the fermentation excited by dung and other manures; which are found to enrich the best pulverized soil again and again, after it is exhausted by crops; and therefore promote vegetation by increasing the quantity of vegetable food. Some manures lose part of their strength by being long exposed to the air. Thus after dung is sufficiently fermented, the longer it lies, the less is its value. Cow-dung dried on the pasture, gathered and laid upon other land, has scarcely any effect; whereas the same quantity carried from the cow-house, or collected by folding the cattle, enriches the land. Hence this kind of manure contains the vegetable food in itself, and does not receive it from the air. Other manures, on the contrary, operate sooner, and with greater violence, the longer they are exposed to the air, before they are used. Lime and marles are of this kind. They are observed to have a strong power of attracting certain qualities from the atmosphere; and operate by communicating to the soil with which they are mixed a power of attracting vegetable food from the air." And further, "some manures exhaust land of its vegetable food, and do not restore it again when immediately applied. This is thought by some to be the case with lime. Land thoroughly limed, after having carried many very good crops, seems to be exhausted, and reduced to a worse situation than before. When in this case lime has been applied a second time, its effects have been found to be far inferior to what they were when first applied. This manure, therefore, seems to operate by dissolving the vegetable food which it meets with in the soil, and fitting it for entering the roots of plants. It may however be noticed, that the exhaustion of land by lime, is owing to bad management and unmerciful forcing it with continued white crops. It is not certain that land will not bear a second liming.

But it is certain that the effects of the lime may be long kept up by the proper application of dung and other saponaceous manures; and there have been instances of the effect of lime continuing forty, fifty, or even a hundred years." It is certain that almost "all kinds of manures contribute to open the soil. Any person may be convinced of this, who will take the trouble to compare a piece of land on which dung or any other manure has been laid, with a piece contiguous that has not been manured; he will find the former much softer, much more free and open than the latter. It must be allowed, therefore, that all manures operate by enlarging the vegetable pasture of plants."

Hence, on account of the great differences that are thus met with in the properties and principles, as well as in the agency of the matters that are made use of as manures, it is difficult to bring them into any sort of practical arrangement. That which tends to shew the nature and qualities of the materials from which they are derived, seems to be the most advantageous in the cultivation and improvement of land.

Manures of the animal Kind.—It may be observed, that the materials which constitute this sort of manure, are of very different kinds, but they may be conveniently distinguished into such as are of a *soft* and *hard* quality; the former comprehending all sorts of animal dungs, and various other animalized materials of a soft nature; the latter including all sorts of hard animal matters, such as bones, horns, hoofs, and different other substances of a similar kind. It has indeed been remarked by a late practical writer, that "all substances of the animal kind, when reduced by the process of putrefaction or other means into a soft, pulpy, or mucilaginous condition, have been shewn, by the experience of the most correct and able cultivators, to afford those matters which are suited to the nutrition and support of plants, with greater readiness, and in a more copious manner, than most other bodies. And chemical analysis has demonstrated, that the chief component materials of such substances, so far as agriculture is concerned, are principally water, jelly, or mucilage, and saccharine oleaginous matters, with small portions of saline and calcareous earthy substances. Hence animal matters, though they agree, in some circumstances, with vegetable productions, each having in common water, saccharine and calcareous matters, are far more compounded; and in animal substances some of these materials are in large proportions, while in vegetables they only exist in a very small degree; and the jelly, which in some measure resembles the gum and mucilage of plants, differs likewise from them, in its having much less tendency to become dry, as well as in its property of attracting humidity from the atmosphere, and of running with great rapidity into the state of putrefaction and decay." And in addition, "all these principles of animal substances are, it is added, resolved by their ultimate decomposition into other matters, such as the different gaseous fluids that have been mentioned above, carbon, phosphorus, lime, &c." It is likewise supposed, that "in animal substances of different sorts, there may be differences in regard to the proportions of these several ingredients or principles; some kinds affording one or more of them in greater abundance than others; while others again are deficient in these, but abound in some of the others. On this supposition, the different effects of substances of the same class, when applied to soils of the same kind, may, it is conceived, be easily accounted for."

It is found, that all substances of this kind, "on being deprived of their vital principle, have a quick tendency to take on or run into the state of putrefaction, a process which is considerably affected and influenced by the circum-

stances under which it is produced. But in the horny and more compact animal matters, this tendency to putrefaction and decomposition is, under similar circumstances, much less rapid than in such as are of a less firm and dense texture. The process of putrefaction is, however, greatly expedited by the conditions under which it takes place being favourable; such as the substance, of whatever kind it may be, possessing sufficient moisture, being exposed to the free action of atmospheric air, and a moderate degree of heat. On various accounts it would likewise appear, that the decomposition of such substances may be promoted by moistening them with water, slightly impregnated with common salt, and perhaps some other saline substances, such as the muriats of magnesia and soda, or sea-salt, as ingeniously suggested by the earl of Dundonald."

And it is thought probable, also, "that the decomposition of some of the more hard and solid substances of this description, such as horns, bones, hoofs, and rotten rags, &c. might be greatly promoted, and rendered more immediately useful, by being reduced into much smaller particles than has been usually the practice, as well as by the application of higher degrees of heat than that of the atmosphere, when it can be done with convenience, and in a sufficiently cheap manner.

It is likewise further stated, that "as the dissolution of animal as well as vegetable matters, is known to be much impeded by their being excluded from the air, or exposed to such degrees of heat as are capable of drying up and taking away their moisture, and by the mixing of such earthy substances with them as are capable, from their open and porous textures, or vitriolic and other qualities, of depriving them of the fluid matters which they contain; it is evident, why under certain circumstances of their being mixed and applied as manures, they may prove less beneficial than in other instances."

There are other circumstances, besides those which have a tendency to render the decomposition of all such matters more quick and expeditious, as those of their being lightly deposited together, and not in too large heaps, or with too much earth mixed with or deposited upon them, by which the air is prevented from acting upon them so extensively as might otherwise be the case. The practice of sprinkling common water over them frequently, especially in hot and dry seasons, and where they are of the more hard and compact kinds, in many instances might, probably, be useful in promoting their dissolution, and rendering it more sudden and complete, consequently, to supply the food of plants more readily, and in greater abundance in any given time.

But the principal substance, and that which is most commonly applied as a manure, is the excrement produced by various kinds of animals, which is found in very different conditions, or states of preparation and richness, in some measure according to the kind of food on which the animal has been fed, and the materials with which it is incorporated or intermixed. The writer of the Middlesex Report says, that "the dung of fat animals is unquestionably more rich, and, consequently, possesses greater powers of fertilization, than the dung of lean ones; and that the quality of the dung of every sort of animal will, in a great measure, be proportioned to the goodness or poverty of its food. Thus, when the animal is fed on oily seeds, such as lint, rape, and others of a similar nature, it will be the most rich; when kept on oil cake, or those seeds which have been deprived of part of their oily matter, the next so; on turnips, carrots, and such like vegetable roots, the next; on the best hay, next; on ordinary hay, next; and on straw, per-

haps,

M A N U R E.

haps, the poorest of all. The dung of lean hard-working cattle, feeding on straw, must, he conceives, be poor indeed."

It may be noticed, that the soil of privies is sometimes met with in a state fit to be applied to the ground, when not much mixed with fluid matters, such as urine, and forms a most excellent manure. It most frequently happens, however, that it is in such a liquid state, as to require other more solid substances to be blended with it, before it can be conveniently applied to the soil. In doing this, a late writer suggests, that "too little regard seems to have in common been paid to the choice of the most proper materials; but it is obvious, that such as can be the most fully acted upon, and the most readily converted into the state suitable for affording the nutrition of vegetables, by the principles of the matters thus employed as manures, must be the most adapted for the purpose, as well as the most beneficial. When, therefore, the manure made use of in this way, is either wholly or principally constituted of such animalized matters as, from their fluidity, are in an improper state or condition to be set on land, without having other substances previously mixed with them, such peaty, boggy, or black vegetable earths should be chosen, as contain large proportions of matter, which the ammonia or volatile alkali so abundantly provided by the decomposition of such substances may exert itself upon, and reduce into that state of solubility which is suitable for promoting the growth of plants. By duly attending to this practice, which has been scientifically handled by the earl of Dundonald, much advantage may be gained, not only in the quantity, but likewise in the quality of the manure. The results of experiments attentively made in this way, indeed clearly demonstrate, that an inconceivable loss is incurred by the inconsiderate practice of exsiccating human excrement, as well as the negligent custom of permitting the liquor or fluid parts of dung heaps to run away. The trials which he has been enabled to make, also lead him to suspect, that it is a much more wasteful practice, to apply these liquors to the ground in their uncombined state, than in conjunction with such earthy materials as have been mentioned above. Besides, much of them must be imperceptibly carried off by the process of evaporation, even when they are carried out in the most favourable seasons of the year; and they cannot, in this way, always be made use of on those soils that contain a sufficient quantity of those earthy materials, or principles, with which they can readily form combinations, and exert their most beneficial and fullest effects."

And it is farther stated in the same practical work, that "most of the later practical writers on agriculture are decidedly of opinion, that the soil of privies is a manure of the most enriching kind, but that its effects are not so lasting as those of many other substances. In the trials which have been lately made with it by Mr. Middleton, "it is said to have produced such astonishing fertility, as to induce him to conclude that it exceeds all other sorts of manure that can be put in competition with it, for the first year after its application. The second year he supposes it of some service, but in the third its effects nearly, if not quite, disappear." The circumstances which render this sort of manure so immediately active in promoting vegetation, and so quickly deprived of its beneficial influence, would seem to be the great quantity of elastic principles which it contains, in a loose state of combination, and the small quantity of earthy matter which it is capable of supplying to the soil, by the last stages of decomposition or decay. This also further shews the advantage of mixing and incorporating with it such kinds

of earthy substances as it may be capable of acting upon, and uniting with. From the causes just noticed, its most active and nutritious properties are almost immediately set at liberty, and either directly contribute to the growth of plants, or form such new combinations as readily become useful for the purpose, while but very little of the earthy material is left behind for further decomposition, and the durable aids of vegetable increase. Mr. Middleton also farther remarks, that this matter is not only prepared in the most suitable manner for the purpose of perfect vegetation, but that the herbage produced by it is capable of fattening the *largest* cattle in *less* time than any other. And the first of these writers knows from repeated experiments, that the finest garden vegetables may be produced by it, when properly employed, without the least injury to their taste, even in the most delicate of them, such as cauliflowers, white brocoli, &c. Instead of a bad taste being communicated to herbage by the use of this manure, it would seem probable, that it considerably improves its flavour, as it has been observed, in the Annals of Agriculture, that the patches of such pastures as had been manured with this substance, were constantly eaten *quite close* by horses, cows, and young cattle, while in other places there was much *longer grass*."

From these facts it is therefore concluded, that "the importance of this substance as a manure is such, that every possible means should be contrived to prevent its loss, which is shamefully permitted, at present, to take place in large towns, to the astonishing extent of more than two-thirds of the whole, and some method made use of to render its conveyance and application more general and convenient. See NIGHT-SOIL.

It is further noticed, that it is not only this, but the dungs of all those animals which feed on such sorts of food as constitute either wholly, or in a great part, the food of man, as has been suggested above, that are, from the experience of practical farmers, found to be more effectual in promoting vegetation, when applied as manures to the ground, than those of such animals as are sustained by such kind of matters as are seldom or ever made use of in that way; "hence it is obvious that the dungs of carnivorous birds, dogs, swine, horses highly fed, poultry, pigeons, and such like animals, must be more powerful in their effects as manures, than those of horses when fed only with hay or grass, neat cattle, sheep, and other animals that live in the same manner. On the same principle, too, it is suggested as not improbable, but that the excrement of insects may be less efficacious as manures than their bodies, as it is well known that by their destruction and decomposition the fertility of land is considerably increased in particular instances. It is probable likewise, that the dungs of some animals may, from the state of their stomachs, and other causes, as well as the nature of their food, be more completely reduced and animalized in its passage through their bodies. That this is the case, at least in granivorous birds, in which the food is subjected to considerable trituration in the course of its digestion, there can be little doubt, and thereby they perhaps become, in some measure, in a condition more suitable to form new combinations, or afford the support of vegetation."

It is conceived, that "this view of the nature of the manures afforded by different animals, should lead the practical agriculturist to be more attentive to the subject, in order that he may render them more abundant, and be capable of employing them under the most favourable circumstances, which cannot be the case while they are, as at present, indiscriminately mixed and blended together in the common dung-heap. That they should not be used in this way is clear.

clear, from the contradictory accounts of them that have been presented to us by various writers and experimenters, which would seem to have been caused by employing them in states of mixture with other substances. By some it is asserted that one load of *swine's-dung* is nearly equal to two of most other sorts, and that it is the richest of all animal manures; in this, however, they would seem to be mistaken, as from trials made by others, it has been shewn that *night-soil* is certainly to be ranked much before it. In some of the ingenious experimental attempts of Mr. Young, it is also shewn, that the dungs of rabbits and poultry are superior to that of pigeons, and greatly more durable. But poultry-dung, in the comparative experiments of Mr. Arbuthnot, was found to be more effectual than that of rabbits, and that of the latter greatly superior to wood-ashes. *Pigeons' dung* has, notwithstanding, been proved by much experience to be a powerful and efficacious manure, and probably, from its abounding with volatile alkaline principles, been concluded to be of a hot or stimulating quality." But it is "from the larger animals that the farmer derives the principal part of the dung that is made use of as a manure in the cultivation and improvement of land; the dung of horses as are highly fed being found, as has been already seen, to be much more valuable for the general purposes of agriculture, and some uses in horticulture, than that which is made by horses when fed with hay or grafs only. Where the animals are kept in the latter way, it is probably not so good as that of well fed cows and neat cattle in general, as in these it may, perhaps, become more animalized from the circumstance of their food being more intimately blended with the *saliva*, or other juices, during the ruminant state of feeding in such animals. The dung of horses is, however, in common, much more disposed to take on the process of putrefaction, and cause more heat, than that of cows and other neat cattle, and indeed these are the chief distinguishing circumstances between them as manures. The dung of neat cattle may also, on account of its less disposition to run into the state of putrefaction, contribute more of the earthy material to the land on which it is applied. Hence, probably, its superior utility on the leaner and poorer, or thinner sorts of soil. The dung and urine of animals, when newly voided, are not, except when the animals are morbid, in a putrescent condition, the length of time in which they remain in their bodies being too short for its fully taking place; but some degree of, or tendency to putridity, is constantly necessary to their discharge; and the means which are further suited to promote it in these substances have been fully described and explained above, when speaking of the nature of animal substances in general.

With respect to the experiments that have been made with the dung of sheep, they shew "that it is equally valuable with that of many other animals that feed in the same way, but agriculturists have not yet turned their attention sufficiently to the means of collecting and preserving it, so that it may be used alone as a manure. The method by which it is at present applied to land, is by folding the animals upon it, under which method of management, on many soils, a great part of the advantage must be derived from the operation or action of the ammonia of their urine upon the vegetable matters contained in them, as well as from the consolidation produced by their treading upon it. See DUNG.

Besides the above, there are many other *soft animal substances* that may be of use for the purpose of improving land as manures, some of which have yet been but little attended to by the farmer. Of this sort are *graves*, or the residuum

which is left after making of candles, and the *scum* which is collected in the boiling or refining of sugar. The author of a late practical work observes, that "different trials upon a small scale, with the former, have fully convinced him, that it is a substance that possesses great powers, when employed as a manure. And although it is a substance which is generally procured at a high price, from its going a great way, and being a lasting manure, it may, probably, be more frequently had recourse to than has hitherto been the case. It is mostly procured in the state of hard compressed square cakes, though sometimes in a soft condition, without having undergone any pressure. When, in the former state, the cakes must be broken down, and reduced into as great a state of division as possible, which may be rather a troublesome and expensive process, except a mill or some proper machine for the purpose be employed. But when it has been even reduced to the finest state possible, it will still be improper for application as a manure, until it has been mixed and incorporated with a pretty large proportion of some rich earthy substance with which it may combine. In the attempts which he has had an opportunity of making with this animal substance, after being much reduced, it has always been blended in the proportion of three or four parts of good vegetable mould, according to the condition of the land, to one of the graves, and then sown as a top-dressing on grafs land, where it has never failed to produce a full crop of hay, considerably greater than that by the usual dressings of dung, and a rich sweet after-grafs, or such as cattle are remarkably fond of feeding upon.

At Enfield, Dr. Wilkinson found, in his trials, that the animal kingdom furnished the strongest manures; among which, graves was the most powerful and durable in its effects. "From one ton to a ton and a half, he considers as sufficient for an acre, according to the state of the land. The cakes, in his practice, were minutely divided, which, on account of their hardness, is an expensive and laborious operation; and that even in this state of minute division, unless mixed with mould, they frequently prove too strong for corn, as he found by experience, on applying them to barley, the grain of which being injured by the rankness of the straw. They are, he conceives, peculiarly adapted to promote the growth of grafs, turnips, and the leguminous plants." And it is further stated, that "eight acres of pebbly loam were manured by him with dung, at the rate of ten loads of the common Middlesex carts *per* acre, except one acre of the poorest and most gravelly, which was dressed with a ton and a half of graves. The turnips where the graves were spread, and the succeeding barley, (which were the crops on the whole piece,) were thicker and more vigorous than where common dung had been laid. He has observed grafs rendered so rank, by the use of graves as a manure, that cattle would not touch it till mellowed by the winter's frost; and even in the succeeding years he was able to trace, by the superior verdure of the grafs, to what extent this manure had been spread. He has also used, with success, salted fish provisions, particularly herrings, which had been spoiled on ship-board, and has found them equal to the graves. In the same manner he has used salt meat, that has become putrid in a long voyage. His general mode of application has been to mix them with mould raised from the head-lands of the field, where they were intended to be spread. By letting them lie for some time, the earth imbibes the strong smell and virtues of the animal manure. Over these he has spread with advantage the liquor drawn from the graves, and the washings of the casks of salted meat, which has been spoiled. When sprinkled immediately

over

MANURE.

over grafs in the fpring, he has alfo obferved this liquor attended with confiderable efficacy in producing a plentiful crop of hay." He adds, that "laft year (1800) he ufed with fuccefs a combination of lime and graves, mixed with mould from the head-lands, in the proportion of about fifty bufhels of lime to a ton of graves. This compofition refembles *fugar feum*, which confifts of lime and bullock's blood." On the whole, "from the large experience he has had of the benefits arifing from *fugar feum*, he thinks this combination of lime and animal matter deferves further investigation." On this it may be obferved, that "there can be little doubt but that by combining lime with animal fubftances, they may be rendered highly active as manures, efpecially when applied on foils that have a fufficiency of thofe earthy fubftances, on which they can exert their full influence. In this way they feem frequently to be rendered more active, than when employed in a fimple uncombined ftate: but experiments are perhaps wanting to fully afcertain the utility and beft means of employing fuch matters." It is however further added, that "lime might thus be combined with bones or woollen rags, or with a compoft of earth and night foil, and would certainly greatly facilitate their converfion into manure, as well as render them more active in producing their effects in the fupport of vegetable crops: and by fome of their properties being abforbed by the lime, during the time of their decomposition, and afterwards parted with more flowly in the foil, they may alfo by fuch means be probably rendered more durable and lafting as manures."

It has been ftated by Dr. Wilkinfon, that "the Arabians, who take great pains to improve their lands, are accuftomed to make large pits: they there put in animal fubftances, and cover them with calcareous or clayey earths; and afterwards thefe earths, which of themfelves are fertile, acquire the properties of the richeft manure." He adds, that "he once ordered a heifer, which died in a field at a diftance from his houfe, to be buried in a compoft of lime and earth. He does not affert that this was its moft profitable application; he had, however, no reafon to complain of his compoft." And "Mr. Wright, in his Survey of the Husbandry of Scotland, he obferves, mentions a compoft of two parts lime, and one part pigeon's dung, to remain mixed until a confiderable fermentation takes place, which is known by the effluvia. Six bolls of this compoft, it is faid, is fufficient for an acre, and will mark itfelf for many years after it has been applied."

There are various other combinations of this nature, which may be fuccefsfully made ufe of for the purpofes of agriculture, when properly made and applied to the foil.

There are ftill other materials of this clafs, that may be employed as manures on land, fuch as the *refufe of glue-makers*, the *cuttings of felt-mongers*, the *clippings of furriers*, the *ferapings of oiled-leather*, and the *chips or wafte of fhoemakers*, where they can be collected in fufficient quantities. Thefe, from their abounding in mucilage and oil, their great attraction for moifture, and their being readily foluble in water, contribute quickly to the fupport of vegetation, but are not probably fo durable in their effects upon land as many other fubftances: hence they fhould only be made ufe of with a view to the immediate crop, which, it is believed, is pretty much the cafe in thofe places where they are capable of being obtained in fuch quantities as to be employed for the purpofes of the farmer.

There are alfo of the fifh kind many fubftances that may be applied in this way, as the *blubber*, remaining after the preparation of oil from the whale, and other large fifhes, and different forts of fmall fifh, both of the fhell and other kinds;

likewife the offals of fuch animals, where they can be procured in large quantities, as in large towns, fea diftricts, and where they are cured or prepared in great numbers for the market. Thefe may be found beneficial in various cafes.

All "thefe fubftances may be readily reduced to that ftate which is proper for manure, by mixing with them a fmall portion of the carbonat of lime, and afterwards, according to circumftances, a quantity, two or three times more than the whole, of good vegetable mould. Shell-fifh, fuch as mufcles, are commonly applied without being mixed with earthy matters; but this is certainly a wafteful practice, as much of their valuable principles is diffipated and loft, as is evident from the highly difagreeable ftench that affails the neighbourhood of the ground on which they have been applied." By mixing good vegetable mould, ferapings of ditches, or peat earth with them, the quantity of the manure would not only be greatly increafed, but the offenfivenefs attending the ufe of fuch manures, in a great meafure, corrected, and the effects of them, in promoting the growth of vegetables, probably rendered more extenfively advantageous to the farmer. And the wafte and refufe of flaughter-houfes and butchers' fops are likewife capable of being prepared and made ufe of in a fimilar manner to that of fifh: but as the manures formed from thefe animal materials are capable of affording much elastic volatile matters, during their decomposition, they of courfe require to be well mixed and blended with fuch earthy fubftances as they can combine with, and render foluble, and in proportions futed to their powers, in order to produce the moft beneficial effects on vegetation, and afford the greateft advantages to the cultivator.

The different forts of woollen rags, hair, feathers, and fuch like fubftances, though frequently made ufe of as manures to land, from their having a lefs portion of oily or mucilaginous matter in their compofition, are probably in their effects inferior. Thefe fubftances muft be cut or chopped into fmall pieces, before they can be advantageoufly applied to the ground as manures.

And the author of "Practical Agriculture" concludes, "from the experiments that have been made with fuch animal fubftances as manures, that it may be inferred, that their effects continue longer than thofe of many fubftances of other kinds;" and that they are highly ufeful materials, in many cafes, for being applied to the foil.

It may be noticed, that among the harder forts of animal fubftances, that are capable of being employed as manures, there are confiderable differences in refpect to their texture and firmnefs: fome being quite firm and folid, fuch as bones, horns, hoofs, fhavings of horn, and fome other fimilar fubftances; while others are more foft and pliable. The bones of all animals are capable of affording much nutritious matter to plants; but thofe which are procured from cattle, that have been killed when fat, are faid to be the beft for the purpofes of manure. Thofe which have been boiled are far inferior, in this view, to thofe which have not undergone that procefs, as by fuch means they are principally robbed of their oily and mucilaginous properties, and confequently muft yield much lefs nourifhment to the immediate crop, whether it be grain or grafs. All thefe forts of fubftances require to be ground down in mills conftituted for the purpofe, or otherwife reduced into fmall pieces, before they are laid on and mixed with the foil, or formed into compofts. It is ftated, that "the ufual method is to reduce them to about the fize of large filberts, but that there can be little doubt but that they would fooner run into the ftate of putrefaction, if they were reduced into ftill fmall particles,

ticles, and thus be made to afford their nutritive properties much more expeditiously, as well as more abundantly; by which means, much less quantities would probably produce equally full effects with the large ones at present made use of: as, where the pieces into which they are broken are left large, they remain a great length of time in the soil, and are only gradually decomposed, without yielding that full supply of nourishment which is necessary for the supporting of crops. And when they have been even prepared in this way, too much earthy materials should not be mixed with or applied upon them; as, where this is done, by preventing the free operation of the air, their decomposition is greatly retarded. Nor should they, upon the same principles, when intended to be incorporated with the soil, be ploughed in too deeply; as, by such a practice, the crop will be deprived of much of the advantages which it might otherwise have obtained from such manure."

It is now well known, that "these substances are constituted of a considerable proportion of mucilaginous or gelatinous matter, a slight portion of fat, and an earthy salt composed of the phosphoric acid and calcareous earth. If great heat be applied, they afford a large quantity of hydrogen gas, carbonic acid gas, and a volatile alkaline liquor. From the nature of these different principles, it is evident that some sorts of substances may be blended and united with the reduced particles of bony matters so as to promote their effects, as manures, in a considerable degree, such as lime, chalk, peat earth, and good vegetable mould, in suitable proportions, as by such means new combinations may be formed highly favourable to the process of vegetation." And that "the consuming of bony or horny substances, by means of fire, for the purpose of obtaining their ashes, is a wasteful dissipating practice that ought never to be attempted by farmers, as by it the mucilaginous and oily materials are driven off and lost, and nothing remains but a phosphat of lime, which can be of but little use in promoting the growth of vegetable crops." Dr. Hunter found, from the application of reduced bones to a poor calcareous soil, with a grain crop in the proportion of 60 bushels to the acre, that the crop was much superior, where this was used, to that which had not been dressed in the same way, and the grass crops afterwards for some length of time, on the same place, displayed a superiority, and appeared more early. He also found the same superiority in turnip crops in different fields, when dressed in the same way. Mr. Young likewise found the effects of bone manures to be very great; but they did not correspond to the quantities employed, as with 25 cart-loads the crop was better than with 50. This curious fact is, however, explained in the opinion of the first of the above writers, by his observing that the soil was an extremely poor one, as in such a case there could only be a small portion of earthy matter for the ammonia and other substances afforded by the decomposition of the bone to act upon, and reduced to that state of solubility the most adapted to the support of vegetation. Hence the immediate benefit that was derived from the manure probably depended solely on the oily and mucilaginous materials that were afforded on their being first applied.

But where bony substances are not broken down into very small particles, it is suspected, from some few trials that the first of the above writers has been enabled to make, that the effects of such substances will be equally, if not more apparent the second than the first year, whether they be used on grass land, or that which is under the plough.

The trials which Dr. Hunter made with ground and unground bones, seem likewise to support this opinion, as he

found, that for the immediate crop the unground bones were of little or no service, but the ground ones of much benefit. What effect the unground ones had the second year is not exactly known; however, from his concluding that these substances are in general, upon grass land, more effectual the second than the first year, it may be easily supposed to have been the case. See BONES.

Manures of the Vegetable Kind.—There are many different sorts of vegetable matters, when deprived of their living property, by undergoing the processes of decomposition, that soon become proper for the nutrition and support of new plants, and fit for being applied as manure. Their reduction into this state is greatly promoted by their being exposed to the full influence of the air, moisture, and a suitable degree of heat. Under these circumstances different substances are evolved, and new combinations formed that become useful in the support of vegetation. These processes or decompositions have been commonly supposed to succeed one another with regularity, from that which is productive of sweetness, to that which is the ultimate result of putrefaction. But Dr. Darwin has suggested, "that it is more probable that different sorts and parts of organized matters, when dead, may undergo many different sorts of chemical changes, and that these may be different according to the differences in the degrees of heat, the quantity of water and of air to which they are exposed. He was led to this supposition from the saccharine process preceding the vinous fermentation, which takes place in certain states of animal stomachs; and from what happens in the germination or sprouting of grain, by which the mealy matter is converted into sugar. And from observing that the acerb juices of some kinds of fruit are rendered sweet by baking, he conceives that the saccharine process may take place in a degree of heat which is about that of boiling water, and that by it the process of fermentation may be altogether prevented from occurring. By destroying or injuring the life of fruits, it is also supposed, that the saccharine process of their juices may be promoted, as is found in many instances; such as the ripening of fruits after being plucked from the trees; their being sooner ripened after being injured by insects, or other means; and after partially cutting, or otherwise injuring the branches of the trees on which they grow; and this, which is termed the saccharine process, it is conjectured, may take place either beneath or upon the earth, in the incipient state of vegetable decomposition, before the vinous fermentation, and thus afford a very nourishing matter to plants." And further, that in the vinous, or process which commences after the saccharine, carbon becomes united with pure air in a large proportion; and that probably at the moment of their combination, while they are in the form of a liquid, and before they assume the gaseous state, they may be taken up by the roots of vegetables. And that, as in the process of putrefaction, carbon is not only changed into carbonic acid, but water decomposed, as is evinced by the smell of hydrogen, it is suspected that these inflammable substances may combine with carbon, as in the case of hydrocarbonate gas, and thereby become capable of being taken up as food by the roots of plants, without their passing into the acid or gaseous states. The union of azote with pure air, towards the close of the putrefactive process, by which nitrous acid is produced, it is likewise conceived, may possibly tend to promote vegetation. This, however, may be promoted from the circumstance of the pure air or oxygen adhering more loosely to its base, the azote, in the formation of this than other acids, and on that account yielding it more readily to the absorbent roots of vegetables. But,

besides these means of supplying the nutrition of plants, as in the decomposition of vegetable substances by the process of putrefaction, the constituent principles of the water which they contain are, as has been just observed, in some measure set at liberty, and the hydrogen, one of them, uniting with the azote which is afforded by the dissolution of vegetable matters, though not in such large proportions as by animal substances, forms ammonia, which, from its ready union with fat and oily matters, and thus rendering them capable of being taken up by the absorbent roots of vegetables, may contribute to the support of vegetation. And, in some instances, where saline, insoluble, earthy matters, or metallic salts are contained in the soils to which manures of this kind are applied, or in which ammonia may be formed, it may decompose them, and by that means contribute to the formation of other new and less noxious compounds, or such as may be more capable of contributing to the growth of vegetables." It is added, that there is another substance which generally prevails in vegetables, and which is supposed to be a simple material, obtained in great abundance from the recrements not only of putrifying vegetable, but animal substances, and calcareous earth, the latter of which is supposed to have been of animal origin in the early periods of the world. This matter, it is thought, when met with in the state of solution, may be taken up entire by the absorbent roots of vegetables, as well as occasionally formed and elaborated by them. It is therefore probable, that different matters fitted to the nutrition and support of plants, as crops, are formed and evolved during the different processes and stages of decomposition of vegetable as well as animal substances. But that in vegetable productions the changes are less rapid than in those of the animal kind, and probably much more varied, according to the various states and textures of the particular substances; as it is obvious, from numerous facts and circumstances, that the more luxuriant and juicy vegetables are much more readily decomposed than such as are dry, and have a ligneous structure. Hence it is, that fresh vegetable matters are much more quickly converted to that state of decay, which is suitable for the supplying vegetable nourishment, than such as straw, hay, wood, and other dry materials of the same nature. It is not improbable, but that some vegetable matters may yield some of the substances that are taken up by the absorbent roots of vegetables in much larger proportions than others; as it has been found that different sorts of grain vary considerably in the proportions of mucilaginous, and what is termed vegeto-animal matter, which they contain; and that grain, potatoes, carrots, and many other roots of the same kind, on being consumed in the open air, afford much larger quantities of alkaline salts than hay, straw, or wood; it is undoubtedly from these and similar causes, that some sorts of vegetable matters, when reduced by means of putrefaction, are found to be so much more effectual as manures than others, when applied under the same circumstances, and to soils in every respect of a similar nature and quality. There is likewise a further circumstance to be attended to in substances of this nature, which is, that in general, when resolved by the ultimate process of putrefaction, they yield larger proportions of earthy materials to the soils on which they are deposited, than most matters of the animal kind, and consequently add more effectually to the substance of the land. And as this vegetable mould, or earth, from various causes, is constantly becoming more extensively and more intimately blended with the other materials of the soils, and, of course, forming new combinations, by which some of those matters

which serve for the nutrition of plants are set at liberty, and brought into the state most proper for being absorbed by the roots of vegetables; it is evident why those manures, which are principally composed of vegetable substances, are more durable in their effects than such as are prepared from many sorts of animal materials.

It is stated that the substances of this kind which are capable of being beneficially converted to manure, are extremely numerous; and consequently suggested that "all kinds of green vegetable productions may be employed in this way; such as the luxuriant weeds of rivers, lakes, ponds, and ditches, fern, and the refuse of different kinds of garden vegetables. Where green materials of this nature are made use of, they should always be cut down while in their juicy state, just before their flowers begin to appear, in order that they may be in the most suitable condition for becoming quickly putrid, and to prevent the injury that might otherwise be sustained from the vegetation of their seeds. They are afterwards to be collected into heaps of a moderate size, and their putrefaction promoted by their being thrown together as lightly as possible, and the occasional sprinkling them with water, if the season be hot and dry; and as lime is found, when applied to vegetables in their green moist state, to disengage from them both hydrogen and azote, by the combination of which volatile alkali is produced, it may be advantageous to blend a portion of lime at first with the heaps, and afterwards add a suitable quantity of peat earth, or good vegetable mould, for the alkali thus formed to act upon. By this method, the quantity of manure from such substances may be greatly augmented, and rendered more valuable. But when dry materials, such as hay, straw of different kinds, fern, and rushes, are made use of, such additions cannot be had recourse to with equal success, unless where much of the dung and urine of animals have been incorporated with them:" their resolution and decay may, however, be greatly promoted by their being kept in a moderate state of moisture, and not permitted to be trodden down too much by cattle, or other means in the farm yards, or other places where they are provided. And another means of supplying vegetable manure, not sufficiently practised, is that of providing full succulent crops of green vegetables; as clover, buck-wheat, tares, vetches, spurry, peas, beans, turnips, and many other similar plants, to be turned down by the plough, in order that they may undergo the putrefactive process under the ground, and by that means be converted into manure, and supply the food of plants. "In this practice it is suggested as probable by a late writer, that great advantage might be obtained, on the principles which we have just stated, by the spreading of a small portion of lime and peat, or rich vegetable earth, over such crops, and then rolling them down, that they may be completely turned in and buried by the plough; an operation which should be performed as quickly as possible afterwards, and where the crops will admit of it, in the summer or early part of autumn, while the sun has the power of promoting the decay of such vegetable matters. By this means, it seems probable that the putrefaction of such crops would not only be much expedited, but the principles thereby set at liberty be capable of exerting their influence much more extensively than where the plants themselves are only employed, and little additional expence be incurred by the farmer in executing the work."

Where crops of this nature can be turned down, in sufficiently hot weather, to ensure their running speedily into a putrid state, it is considered by some as a better and more

advantageous practice, especially where manures of other kinds are scarce, than that of obtaining it by consuming them by the feeding or soiling of cattle, which, under other circumstances, is certainly an excellent mode, and one which should never be lost sight of by the farmer.

Besides these there is another plant of the vegetable kind which is capable of being employed as a manure with great advantage, and which should never be overlooked where it is within the reach of the farmer. This is sea-weed, (*quercus marina*.) In the management of this substance there is considerable diversity: "in some districts it is the practice to spread it upon the land as soon as possible after being cut from the borders of the rocks on the different sea-coasts, or collected after being left by the tides, and to plough it in; where this method is adopted, it is advised that as little time as possible should be suffered to elapse after the cutting, or collecting of the weed, before it is ploughed down; for as the plant in its green or succulent state readily decays and becomes putrid, if there be any considerable delay in the performance of the business, especially when the weather is hot, much of its valuable properties as a manure is dissipated, and carried away by means of evaporation, as is sufficiently shewn by the pungent and disagreeable smell that issues from it, on its being thrown upon the land while undergoing the process of putrefaction: and, besides, when it is suffered to become dry and hard before it is turned into the ground, the parts that remain are considerably longer before they become decomposed, and reduced into the state suitable for affording the nourishment and support of vegetable crops." It is believed to be, on these accounts, as well as that of the weed affording but little earthy matter in proportion to its bulk, on its decomposition, that it is found, in general, to be less permanent in its effects as a manure, than some other vegetable matters. Something may likewise depend on the goodness and luxuriance of the weed itself, and the state which it is in when gathered from the shores, or cut from the sides of the rocks. As in most other plants, this will undoubtedly be in the most proper condition for the purposes of being converted into manure, when cut or collected in the most succulent state of its growth, before it has become too old. Another method of practice with this weed, is that of collecting it into large heaps, and letting it remain exposed in that state to the influence of the weather until it be completely rotten, and in a condition to be put upon the land; but as the plant contains in its composition a large proportion of saline matters, which, during the state of its decomposition, or decay, are brought into activity, it is plain that by such a method of proceeding much loss must be sustained, not only from the dissipation of the volatile and more fluid active parts, by the action of the sun and wind, but by the rains dissolving and carrying down the saline materials that may have been formed. When it is not immediately to be applied as a manure, it would therefore seem to be the most economical and advantageous mode, especially where the weed is fresh, to first blend a portion of quick lime with the heaps, and then have a sufficient quantity of fresh good earth, mould, or other similar material, placed beneath them, as well as mixed with and covered over them, in order that the substances afforded by the dissolution of the weed may have something to mix with and act upon, and be prevented from being washed away by rains. In this way, the quantity of manure may be much increased, and at the same time its effects rendered considerably more lasting in the land. It is the custom in the islands of Jersey and Guernsey, where this weed is ex-

tensively employed as a manure, to cut it in the early part of the spring, and about the month of July; the first cutting, in most cases, being immediately made use of as a manure for barley and pasture lands, and the latter principally converted to the purpose of fuel, the ashes only being employed as manure. In the practice of consuming the plant in its dry state, however necessary it may be there from the great scarcity of fuel, the loss in manure is extremely great, as the quantity of ashes thus produced are very small in proportion to the weed which is consumed. Such weed as is collected after having been thrown upon the shore by the tides, is found to be much inferior as a manure to that which is cut from the rocks and made use of in its green juicy state. This should, therefore, be well attended to where this plant is in use.

Another material of the vegetable kind, that may be had recourse to as a manure, is that of such bark as has been made use of for the purpose of tanning leather. This substance, when made use of in this way, should be collected into moderate sized heaps, before it has become dry by too much exposure to the heat of the sun and wind; and then have a quantity of lime mingled with it, and be kept slightly moistened with water, as by this means its putrefaction and decay may be greatly promoted. When intended to be applied to grass lands, it should be considerably more reduced towards the state of vegetable mould, than when laid on land for the purpose of supporting crops of the grain kind. There is another point that ought to be regarded in this material, which is, that as during its decomposition much heat is produced, and many elastic matters set at liberty, it would seem as a manure to be more adapted to the stiff, cold, and heavy soils, than those of the lighter kinds; a fact which the experience of agriculturists has shewn to be well founded in general.

And mud taken from the bottom of rivers, ponds, and other places where water has stagnated for some time, fresh or maiden earth from the borders of fields or other places, and the scourings of old ditches, are other substances that may be occasionally employed with advantage as manures, as being principally composed of the recrement of decayed vegetable matters. They should not, however, be put upon grounds, especially those in the state of grass, until they have been reduced into a considerable degree of fineness, by means of frequent turning over, and the mixing of portions of lime, rotten dung, or other materials of the same kind, with them, in order to promote and render the decay of the more solid parts complete. In the application of manures prepared from substances of this sort, as top dressings to land, in the state of grass, they should not be spread on too thickly, or in too large proportions at one time, as where that is the case great injury is often done to the succeeding crop, the grass not being able to spread itself completely over the surface of the ground.

There is another material in the dust which is separated from malt in drying, mixed with the tails, usually denominated *coombs*, which, where they can be procured in large quantities, as in the malting districts, may be made use of for the purpose of manure. In a paper, by Mr. Farey, in the Annals of Agriculture, it is remarked, that the black malt-dust, such as falls through the kiln-plate in the operation of drying, is greatly preferable to the white, on account of the seeds of charlock, with which it abounds, being destroyed by the heat, and rendered fit for manure. The heat thus applied, by destroying the vegetative principle of such seeds where they exist, probably renders them and the dust more readily disposed to take on the process

of decay and become putrid, and thereby afford the nutrition of vegetables more quickly as well as more abundantly than in other circumstances. It is well hinted by a late writer that "this, as well as saw-dust, where they can be had at a cheap rate, may be considerably improved as manures by incorporating them, in pretty large quantities, with the dung and urine of animals, as by strewing them in the bottoms of poultry and pigeon houses, dung heaps, and necessaries; and also in the bottoms of reservoirs into which the urine of cattle, and the soap-suds after washing are emptied; from the action of these matters upon them, they are found to become more quickly in a state to be used with advantage as manures." And it is added, that "manures of this sort have been found very beneficial when applied in the proportion of four quarters to the acre, sown with the crop for which it is employed. See *MALT Duff*."

The husks, or cakes, which are left after different oily seeds, such as those of rape, cole, &c. have been subjected to pressure in mills in order to obtain their oil, are other materials that may be converted to the purpose of manure. These substances are generally prepared for application by being reduced into the state of coarse powder, by mills or other suitable means, and then sown by the hand, and harrowed in with the seed of the crop for which they are used. Some farmers, likewise, advise their being mixed, when thus reduced, thinly, with the materials of such dunghills as are deficient in richness, as where they have been made by lean stock with a large proportion of litter. On turning over heaps of this kind, about a ton of cake is recommended to be well and evenly incorporated with every twenty or thirty tons of the dunghill compost; by this practice a rich and good manure is said to be formed. It is asserted, that "the success of these substances, when made use of as manures, has been found to depend, in a great measure, upon the falling of rain soon after they have been put upon the land, as in dry seasons little benefit has been derived from their application." The reason of this seems to be, according to a late author, "that as the cake when used is mostly in an extremely hard and dry state, it does not undergo that decomposition which is necessary, until it has been moistened by the rain, by which it is rendered capable of running quickly into the state of putrefaction, and consequently of affording such matters as are suitable for the support of plants." And it is added, that "when applied without being incorporated with any other substance, it is mostly laid on to the amount of four or five quarters to the acre, according to the condition of the land."

And there is still another vegetable matter found in the refuse or pulp of pears and apples which have been ground, and the liquor squeezed from them, that may likewise be converted to the purpose of a manure, in the districts where cyder is prepared in large quantities. But it is advised that some heavy substance, such as good earth with a little dung, should be mixed with it before it is put upon the soil, as by being blended with such materials it may be more conveniently and more extensively applied to the land, and probably with better effect.

Manures of the Earthy or Fossil Kind.—It is well known that there are a great many different sorts of materials of this nature that may be brought into use for the purpose of improving the condition of lands. The chief of the substances of this description are of the calcareous kind, which are found to "produce effects more or less powerful in promoting the growth of vegetable crops, in some measure, according to the state and quantity in which they are applied, the nature of the soils in which they are employed, and the properties of the matters with which they are com-

bined. For though calcareous materials have been made use of as manures for a very great length of time, and have been applied in various ways, difficulties still remain concerning the manner of their operation, in many cases, which seem principally, however, to proceed from the want of proper discrimination in respect to the state of the different calcareous substances at the time of their application, and their being made use of to different soils without a sufficient distinction as to the properties of the materials of which they are constituted or composed." The inquiries of a late experimental writer "have likewise shewn it necessary to attend to another circumstance, which is, the substances the calcareous material is combined with; as he has found that where magnesia is in union with the calcareous matter, it is not by any means so beneficial for the purposes of manure and promoting vegetation, as where no such mixture or combination is present, especially when used in the same proportions." This is, however, a point that requires further examination, and which is by no means fully decided. It has also been observed, "that from sand entering largely into the composition of lime-stone or other calcareous matter, in some cases, as it is a substance of much greater specific gravity than pure caustic lime, considerable differences in its effects as a manure may be produced." On these accounts it is concluded, that though lime may be produced from chalk, marble, different lime-stones, coral and shells, by subjecting them to such degrees of heat as are necessary to expel or disengage the carbonic acid or fixed air that they contain, which is apparently of the same quality, it may vary in its effects when employed for the purposes of the farmer. See *LIME* and *LIME-STONE*.

It is evident that lime, when newly burned, or before it becomes loaded or saturated with the moisture and carbonic acid, or fixed air, contained in the atmosphere, which, from their strong tendencies to combine or unite with it, generally soon takes place, is in its great state of activity, and from the power which it possesses of breaking down and destroying the texture and organization of such animal and vegetable substances as come in contact with it, termed *caustic* or *quick* lime. When, under these circumstances, it is applied to grounds which abound either with fresh vegetable matters, or such as have undergone some degree of change, by being buried in the soil, as in moory and heathy mountain-land, peaty or boggy earth, and all such soils as have long remained in their original uncultivated state, covered with a variety of coarse plants, it is said to be "found to produce beneficial effects; in the first case probably by its ready action on the different materials of the green plants, by which it disengages from them hydrogen and azote, from the subsequent combination of which ammonia or volatile alkali is produced, a substance which has great power in promoting vegetation, as is seen in cases where substances that contain this matter in large quantities are used as manures; and in the second place, by its combination with the carbonaceous matter of such soils, or with that of the various animal and vegetable matters which are contained in them, in some of the stages of their putrefaction or decay, and by this means rendering it soluble in water, and thereby capable of being taken up as food by the absorbent roots of vegetables." And, "that though lime in its pure or caustic state retards, in some degree, the process of putrefaction, especially when used in any large quantity, it is probable, that by its power of corroding and dissolving the hard and fibrous parts of vegetable and other matters, as is shewn by its quickly reducing the ligneous particles of bark, which has been employed in the process of tanning, to the state of mould, it may bring the abundant vegetable and other ma-

MANURE.

terials contained in such sorts of land quickly into that earthy condition, in which they afford the nourishment and support of crops, which by the process of putrefaction, and insect digestion, could only have been performed in a very slow and gradual manner." Further, from its well-known property of destroying different kinds of insects, such as worms, snails, slugs, grubs, &c. which are mostly abundant in rich fresh soils, it may furnish much nutritious matter for the purpose of promoting the growth of plants as crops. There is, likewise, another way in which it may contribute to the same end, which is, from its having a greater tendency to combine with mucilaginous oily matters than with fixed alkalies, as a kind of calcareous soap may in some cases be formed that may contribute, in its liquid state, to the nourishment of plants, as has been noticed by Mr. Nicholson, in his Philosophical Journal.

Besides, it has also the power, when mixed with clayey soils which do not possess too great a degree of humidity, of rendering them less stiff and tenacious, consequently more suitable for admitting the small fibrous roots of vegetables, which is effected, not only by the heat and other elastic matters that are evolved during the period of its becoming saturated with the moisture and fixed air, or carbonic acid, which they contain, but also by being thereby more intimately and minutely incorporated with them, from the fine impalpable powdery state to which it is necessarily reduced. And when in such soils the sulphuric acid is predominant, it may also produce good effects, by forming with it a kind of gypseous compound, and in cases where other acids are present that are prejudicial to vegetation, by the power which it possesses of neutralizing them, and thus preventing their hurtful effects. And it is also further probable, that when burnt from the magnesian lime-stone, it may prove serviceable when applied to clayey or other soils that contain the sulphuric acid, usually denominated sour lands by farmers, by forming a sort of Epsom salt in the ground, a substance which the experiments of Dr. Home have long ago shewn to be favourable to vegetation, when laid on ground in small quantities.

It is found that this substance, on exposure to the atmosphere for some time, undergoes a considerable change, being rendered mild by the absorption of the carbonic acid or fixed air that surrounds it. In this state of combination, it has been termed, by modern chemists, *carbonate of lime*, or *effete lime*: in which condition its power of acting upon, destroying and breaking down the texture of organized matters, is greatly diminished. It has still, however, the effect of promoting their dissolution by forwarding the natural process of putrefaction, as is proved by the compost dung-heaps with which it has been blended becoming more quickly in a proper state to be applied to land, than in the contrary cases. By this means it consequently contributes much to the support of vegetation: and it has been lately suggested, that when incorporated with such compost of soil and manure, as are in a state of generating nitrous acid, it may arrest the acid as it forms, by which means a calcareous nitre is produced, and thus the exhalation and ready escape of a nutritious material be guarded against. It is further conceived, also, that the combination of lime with carbonic acid, by rendering it soluble in water in its fluid state, without being expanded into gas or vapour, may supply much carbonaceous matter for the support of vegetation. And by the property it possesses of super-saturating or overloading itself with moisture, by attracting or drawing it away from the air, in contact with the surface of the ground and the earth underneath, and after depriving them of it, and the carbonic acid which they contained, permitting them to escape again,

as is evident in the case of new plastered walls, it may be of considerable utility when applied to the dry and sandy sorts of soil, by affording moisture and such aerial matters to the roots of the vegetable crops; which it is capable of supplying in a very equal and extensive manner, from the extreme state of pulverization to which it is reduced when flaked by the dampness of the atmosphere, or by a very gentle fall of moisture. And in addition to these modes of promoting the growth of vegetable crops, it has been supposed by Dr. Darwin, that calcareous earth, by containing phosphorus, may be useful, as by its union with it a kind of hepar may be produced, and the phosphorus thereby rendered soluble in water, without becoming an acid by means of its combination with oxygen or vital air. It is conceived that phosphorus is probably as necessary an ingredient in vegetable as animal bodies, as is evident, it is supposed, from the phosphoric light seen on rotten wood, in some of the stages of putrefaction; in which, it is believed, the phosphorus is set at liberty from the calcareous earth, or from the fixed alkali, or the carbon of the decomposing wood, and acquires oxygen from the atmosphere, both warmth and light being emitted during their union. And it may, perhaps, more frequently exist in the form of phosphoric acid in vegetables, and be thus readily combined with their calcareous earth, or be separated from its acid by the carbon of the vegetable, during the time of calcination, as well as in the process of putrefaction. It is, therefore, plain, from this account of the nature and properties of lime, that it may be made use of in one or other of its states more generally to soils, than has been commonly supposed. But it should never be applied without duly attending to the nature and quality of the soil on which it is to be laid, as upon this circumstance, its success in a great measure depends in all cases.

It may be noticed, that the trials that have been made by farmers with this manure, sufficiently shew, that the more minutely lime is blended and incorporated with the mould of the land on which it is applied, the more full and complete are the effects which it affords in supporting the growth of different sorts of crops. In support of this, it has been remarked by Dr. Anderfon, that "if a heap of lime of a considerable thickness shall have been ever so long on one spot, and be afterwards carried clean away from it, so that none of the particles of the lime remain to be mixed with the soil, that spot will not be richer, or carry more luxuriant crops, than the places around it; which, every one knows, is not the case with regard to dung." And further, that "if lime be spread upon the surface of the soil, and allowed to remain there without being ploughed in, its effects will scarcely be perceived for several years, till it has had time gradually to sink through the sward, and mix with the soil; after which its effects begin to be perceived, although much less sensibly than if the same had been intimately mixed with the soil by means of the plough and harrow." The same writer adds, that he is not a stranger to the improvements that have been made in Derbyshire by means of lime, without the plough; but this, he thinks, is no exception to what he has said. The effects are slow, though certain. "Those who inhabit counties that do not admit of the plough, are often advised to lay lime upon the grass, and are made to believe that their pasture will be immediately mended by it, nearly in the same perceptible manner as if it had been dunged. This he has tried, and has seen it tried by others; but always found that the grass for the first year was rather hurt than benefited by it; nor was it so much improved in succeeding years, as if the same quantity of lime had been applied and immediately mixed with the soil.

M A N U R E.

In this mode of applying lime, it is long, he conceives, before it yields a proper return; and is not to be recommended to a poor man, unless where necessity obliges him to practise it." On this supposition, it is conceived, that lime may be employed much more advantageously when made use of, even in small proportions, than such calcareous substances as have been reduced into the state of powder without calcination; but much must depend on the mode in which lime is laid on. "If it is spread as soon as it is slaked, while yet in a powdery state, a very small quantity may be made to cover the whole surface of the ground, and to touch an exceedingly great number of particles of earth; but if it is suffered to lie for some time after slaking, and to get so much moisture as to make it run into clods, or cake into large lumps, it can never be again divided into such small parts; and therefore a much greater quantity is necessary to produce the same effect, than if it had been applied in its powdery state. But if the soil is afterwards to be continued long in tillage, (as these clods are annually broken smaller by the action of the plough and harrows,) the lime must continue to exert its influence anew upon the soil for a great course of years; it will produce an effect nearly similar to that which would be experienced, by annually strewing a small quantity of powdered lime over the whole surface of the soil: but as the price of the lime must, in the first case, be paid by the farmer altogether at the beginning, which only comes to be successively demanded in the other case, this deserves to be attended to, as it may become a consideration of some importance where lime is dear, and money not very plentiful."

With respect to the use of lime, there is another point to be considered, which is, the quantity that may be necessary. The opinions of practical farmers are much at variance in respect to this point, some contending that a small quantity can only be applied with safety and advantage, while others maintain that scarcely too great a proportion can be made use of. It is plain, a late writer thinks, "from the differences that take place in soils, that no particular proportion can be suitable in every case, but that it must be varied very considerably according to the circumstances, as well as from the situation or condition of the land on which it is laid, and the proportion of real calcareous matter that may be contained in the lime that is to be applied. As it has been shewn that lime, when in its most active state, soon becomes reduced so as to be perfectly mild by its property of absorbing moisture, and the carbonic acid from the air, there can be little danger of injury from its caustic quality, though it may, on its first application, have a tendency to unite with and destroy such green or other vegetable productions as may be present." It is, however, the remark of an able farmer, that "most kinds of *stone-lime* should be applied with a sparing hand, and with a considerable degree of caution, as the *caustic* quality is many times greater in *this* than in lime made from chalk." He has had many opportunities, he asserts, of seeing total barrenness induced by a *too liberal use of it*; very generally at the several places where the carts were stopped for the men to spread it, at the bottoms of every heap, and once an entire close.

It is well known that lime has been made use of as a manure in different proportions, from one hundred to six or seven hundred bushels on the acre, on different sorts of soil, by some under similar circumstances, with benefits in proportion to the quantities applied. Besides, accidental experiments in Dr. Anderson's practice have demonstrated that it may be used in still larger proportions, with advantageous effects. And he concludes, that "on soils which do not naturally abound with chalk, or other calcareous

matter, there is less danger in giving too much, than too little, except in those cases where an over-luxuriance is dreaded in the land."

It may be observed, that the permanency of the effects of this material in promoting the growth of vegetable crops, must be different, according to the difference of circumstances in the land to which it is applied; the proportion of it that is made use of, the kind of crop that is cultivated, and other causes of the same sort. But from the facts that have been recorded by practical writers, in respect to its lasting powers of disposing lands on which it has been laid to the growth of particular sorts of crops in preference to others; of rendering the operation of other kinds of manure, and other methods of culture, more effectual than where it had never been used; that it affords useful changes in the soils to which it is applied. Of this we have an additional proof in the well-known circumstance of the quality of the grain, from such lands as have been limed being much improved, having a thinner skin, and yielding much more flour than that from ground where it has never been employed; which is supposed, by a late writer, to proceed from its containing more starch and less mucilage, on account of the tendency of the lime to promote the conversion of the latter substance into the former, by expediting the ripening of the grain. This is a circumstance which also shews the utility of this manure in those kinds of land that are late in bringing their grain crops to perfection, whether from the nature of their soils, situations, or other circumstances.

It is obvious that this substance, with proper care, may be useful on many different sorts of land, but in its active state it is laid on to the most advantage on those of the moory, peaty, heathy, and other kinds that abound in coarse vegetable matter. On which account it is, perhaps, that it has been found by experience to be equally, if not more beneficial, on poor than on rich soils; and its requiring to be mixed and incorporated with but a small portion of earth or mould, to render it highly productive, is in favour of the same thing. From these facts it may be concluded, that this substance, besides being useful when blended with soils, in rendering the matters they contain proper for the reception of plants, is beneficial in supplying such materials as contribute to their growth and increase. See LIME.

Other materials, such as lime-stone, and various hard calcareous bodies, which, without being subjected to the process of calcination by heat, may, in some cases, as where fuel cannot be procured to burn them into lime, be beneficially applied for the amelioration of land, as has been shewn by numerous experiments. When thus used they should be well pulverized, by such mechanical means as can be cheaply performed; much of the advantage to be derived from them probably depending upon their being reduced into a considerable state of fineness, by which they may be more minutely blended with the mould of the soils on which they are applied, and of course act upon and afford nutritious principles more extensively, for the support of crops; and at the same time render the heavy and more cohesive soils lighter, by being more uniformly incorporated with their clayey and earthy materials. But as such substances can never be reduced, by any sort of machinery, to the fine powdery state to which they are capable of being carried by means of calcination, it is probable that, when employed upon land, they will be less beneficial in many cases, than when used in the state of lime. The same principle likewise holds good, probably, in respect to the scrapings of roads, made with calcareous and other substances, which are found beneficial in different instances, as a large portion of them is in the state of an extremely fine

from the attrition caused in different ways. It has been suggested, by the experiments of an able philosophical inquirer, "that even magnesian lime-stone is made use of in this state of reduction, without being converted into lime; it may not be so friendly to vegetation as that which is perfectly calcareous, especially when employed in the same proportions; a circumstance which may, in some degree, account for the difference which has been observed in the utility of such substances as manures." It is obvious that such lime-stones as contain the largest proportions of argillaceous earth in their compositions, when employed in this reduced state, must be the most proper for the thin light soils: as by that means the depth and texture of them may be increased to the great advantage of the crops. In the application of this sort of material to land, the farmer should be attentive to the state or condition to which it is reduced, as well as the nature of the soil, and adapt the quantities as much as possible to them. See LIME-STONE.

Lime-stone gravel is another substance of this nature, which has been successfully employed in Ireland; it is a kind of stony marle, which might probably be equally or more beneficial, in much less quantities, by having the stony lumps which it contains first more perfectly reduced; as it has been found that where the pieces are large, a much greater proportion is required, and the effects are slower than when made use of in a more reduced state of powder. See LIME-STONE Gravel.

And chalk is another material of the same sort, capable of producing beneficial effects on land, when applied in a proper manner in its uncalcined state. From the portion of argillaceous or clayey matter united with it in some cases, it partakes of the nature of marle. It has been stated that, where it is made use of to the more stiff, clayey, loamy, and heavy sorts of soil, it should, in most cases, be as much pulverized and reduced as possible before it is laid on, in order that it may be spread with greater exactness, and be more regularly mixed and blended with the stiff and compact materials of such lands; from which they may be rendered more capable of admitting the fibrous roots of vegetable crops to spread themselves in them, and thereby take in more perfectly the nutritious matters which are presented to them." That this is an useful practice, is evident from the circumstance of farmers, in most of the districts where chalk is employed as a manure, finding it more beneficial when made use of in the spring, after having been dug up in the autumn, and exposed to the frost and moisture through the following winter, as by that means it is much pulverized and broken down. The advantage of breaking down the large lumps is also in favour of the same opinion. It is stated by the author of Practical Agriculture, that "it would probably, however, be a still more advantageous practice to break it down, and apply it as quickly as possible, after digging it out of the pit; as by leaving it exposed to the atmosphere for some length of time, it not only becomes hard, but likewise less soluble, and therefore less proper for the purposes of manure. Hence it probably is, that farmers, where the chalk husbandry is practised, find the dressings more efficacious when the chalk is dug from a considerable depth, than where it lies near the surface of the ground. In the dry and light soils too it may, probably, be more serviceable in this reduced and powdery state, from the circumstance of its possessing more moisture, on account of a more extended surface being exposed to the air, and the particles of the soil, from which it may absorb and attract it, and afterwards part with or afford it in a more regular and uniform manner, to the absorbent roots of the growing vegetable crops. The observations of practical farmers,

however, invariably shew, that on such soils it is much more beneficial when made use of in the form of compost, either with rich peat, or vegetable earth and mould, or with good dung; as by this means a great defect in such kinds of land, the want of well reduced vegetable matter, is remedied, and a greater proportion of nutritious materials afforded for the support of crops."

But in using it upon wet and poachy kinds of ground, there is not, probably, the same necessity for its being reduced to a great degree of fineness, as it may be apt, under such circumstances, to dissolve, and sink down too much by being so greatly diluted with water, while in the rounder state it may be retained near the surface, and thereby be capable of absorbing and taking away the super-abundant surface-moisture more effectually. In such soils, where the principal intention is the destruction of moss, rushes, and other coarse plants, the growth of which depends upon a great degree of superficial wetness, it may, however, be employed to most advantage in a state of considerable reduction, as from its greater readiness to sink down, it may the more quickly take away from their roots the excessive moisture that supports them. When acids exist under certain combinations in such soils, it may, probably, also neutralize them more readily when applied in its pulverized state, than in the lumpy one in which it is mostly laid on such lands.

It may be stated, that the quantity or proportion in which it may be applied, must depend, in a great measure, upon the state of the soil, the nature of the crop, and the intention with which it is employed. In the southern districts it is laid on the stiff clayey soils in large quantities, as from twelve to fourteen or fifteen waggon loads, or from fifteen to twenty hundred weight each, to the acre; and on the sandy soils in some parts of Kent, at the rate of one hundred and sixty bushels to the acre. On deep and strong kinds of soil, the practice is mostly either to lay it on the clover leys while feeding off, or upon the summer fallows. And it is frequently used in the form of compost on light soils, to the wheat fallows, as well as grass grounds. But as it cannot be reduced to the state of powdery fineness of lime, and cannot of course be so equally spread out, or so minutely blended with the soil, much larger proportions must be employed to produce the same effects upon the soil; three or four times the quantity is in most cases requisite. On this account it has been suggested, that where it must be carried from a great distance in its wet, heavy state, it may be the most economical practice to have it first converted into the state of lime, as it will thereby be much more easily conveyed to the places in which it is wanted. See CHALK.

There is another substance of this nature, in some sorts of marle which may be made use of as manure to different sorts of soils with great benefit, according to the difference of their nature.

Where substances of this kind are laid upon land, for the purpose of supporting immediate crops of either corn or grass, the most crumbly, or those the most readily reducible into a powdery state, are the most proper; but where they are laid on with the intention only of assisting future crops, or of producing more lasting effects, those that are more hard, and less disposed to fall into pieces, may be more advantageously employed, the first of which is shewn to be the case, by the observation of practical husbandmen in marling districts, that it does not exert its full effects on the soil until it has been well mixed and incorporated with it by frequent aration, and by the practice of letting it remain some time on the surface of the ground before it is

turned down, from which it becomes much reduced into a powdery state: and the latter, by the circumstance of the harder forts remaining a great length of time upon, or within, the ground, before they are fully decomposed, or broken and carried down into the soil to be blended with it.

It is clear that substances of this kind produce beneficial effects on most sorts of soil in their different forms; the shell, stone, and those kinds of marle which abound most with calcareous earth, or which have sand in their composition, are the most adapted to the strong, stiff, clayey soils, as by the insinuation of such matters they are not only rendered more light and friable, but a great part of the injurious moisture which they contain is removed. While those in which clay considerably predominates, are found more advantageous in the light, dry, sandy, gravelly, and loamy soils, as by such substances the defects of lightness are remedied, and the necessary moisture in some measure preferred. The writer of the Middlesex Report states, that "on the stronger sorts of loamy soil, clayey marle will mostly be improper, as it has much tendency to render such sorts of land more wet and adhesive, by which they may be greatly injured. These have been found to be the effects resulting from the application of it even upon a temperate loam, in some parts of Suffex. And, besides, it is sometimes apt to bring up coltsfoot, a weed which is difficult to be eradicated."

In respect to the quantity or proportion of these substances which is applied, it differs considerably in different districts, which in some degree depends upon the nature of the soils; the heavy, clayey, or loamy, demanding in general a much larger proportion than the light, sandy, or gravelly sorts. The average quantity employed may be estimated at from about one to four or more cubic roods of sixty-four yards to the statute acre, according to the state of the marle, and particular nature and condition of the ground on which it is laid. According to the Survey of Lancashire, "it may in many cases be the most advisable practice not to apply too thick a covering at one time, but to have recourse to light dressings more frequently, as by such a method the fertility of the land may be better preferred and kept up, and the crops be rendered more full and abundant."

It is stated in a practical work, that manure of this sort is employed on lands in a course of tillage, as well as in grass. On the former it is often made use of as a preparation for barley, turnips, and other similar crops, or applied upon clover or other new leys, previous to their being ploughed up for wheat; in which modes of making use of it, the common practice is to leave it spread out upon the surface for some length of time before it is turned in, in order that it may be well reduced into a powdery form; for the more perfectly the marle is broken down and spread out, the more effectual it is found in promoting the growth of the crops. It has been noticed, that in its application in the latter case "it is frequently laid on in too large quantities, or left too long in its lumpy state; from both which circumstances disadvantages are produced to the growth of the grass, when either to be cut for hay, or fed off by cattle; as by the former, where the marle contains much of the argillaceous material, a kind of crust is formed that prevents its springing, as happens where the stiff mud of ponds, and such like manures, are too thickly laid on lands; and from the latter, the grass is not only injured by the small clods, as is experienced where imperfectly reduced clayey earth is applied, but the effects of the manure are prevented from being fully exerted on account of its not being well broken, and carried down to the absorbent roots of the grasses, by the fre-

quent rains that may take place after its application." And that "when employed in large proportions, whether upon the heavier or lighter sorts of land, a considerable space of time appears, from experience, to be required to elapse, before it can with advantage be had recourse to again; for if this circumstance be not properly attended to, or too many white crops be successively taken, a very great degree of exhaustion is soon produced, as has been experienced in many of the marling counties of England, and in Forfarshire in Scotland. These injurious consequences are, however, found to be easily prevented, by adopting the alternating system of corn and grass, or other green crops." And it is further suggested as probable, "that by taking corn and grass crops in succession, or, after having one or two grain crops, letting the land be laid down for two or three years with artificial grasses, the application of marle in small quantities might be more frequently renewed, to the great advantage of the farmer, and the improvement of the land. In some of the places where this kind of manure is made use of, as in Lancashire, something of this practice is adopted with much benefit. And when mixed with dung and other substances, in the form of compost, it is generally found capable of being repeated, at short intervals, with the most beneficial effects." From these facts, the writer therefore concludes, "that such injuries are rather to be ascribed to the mode of cropping, than to the nature of the manure. Something may also, he supposes, depend on the manner in which it is applied, as it has been found to be more efficacious, when well mixed and incorporated with the soil, than where this has not been the case; and that, as it has been found highly advantageous in promoting and bettering the condition of the grass-lands in some districts, while in others it has been objected to as injuring them, it is still farther probable, he conceives, that much depends on the state and manner of its being put in or upon lands, and that it is only where it is laid on in a moderate suitable proportion, and after it has been well broken down and reduced into a fine powdery form, so that it may be very minutely and intimately blended with the soil, that its best effects can be exerted upon the land.

And the general method of digging it up in the summer season, and spreading it over the ground in its lumpy state, in order that it may be acted upon and reduced by the heat of the sun, and the frosts during the succeeding winter, is a proof of the same conclusion. See MARLE.

Another useful material as manure, is found in the shelly sand, found in beds in the hollows, and other parts of the sea-coast, in different districts, as containing not only calcareous matter, in a state of considerable fineness, but a portion of animal and vegetable substances, with a small quantity of the muriate of soda or sea-salt; the last of which, from its well-known property of promoting the process of putrefaction in animal and vegetable matters, when in such proportions, and that of destroying different kinds of living insects, may contribute greatly to the good effects experienced from it. This is rendered highly probable, from the circumstance of that which is taken from underneath the water, or from such banks and places as are daily covered by the tides, being the most efficacious when applied to the soil. The proportion of calcareous matter contained in substances of this sort vary very much, according to the particular circumstances of them. It has been observed, that "where the quantity of calcareous matter is large, and in a very reduced or attenuated state, it is by much the most valuable; as when there is much sand amongst it, a much larger quantity will be required, and the expence of application be of course much increased." It is conceived that this substance

is "more proper for the clayey or loamy soils than those of the lighter kinds, especially where the proportion of the calcareous ingredient is large. When equally spread, and well incorporated with such lands, it is generally found to produce good effects for a great length of time." And it has been observed by Dr. Anderson, that "a considerable less quantity of calcareous matter, when in this fine state, will have a more sensible effect, than when it is in that of any kind of earthy marle, as it admits of being spread over the ground with greater equality, and of being more minutely and intimately blended with the soil."

With regard to the quantity employed, it must obviously be different, according to the nature and circumstances of the soil, as well as the sand; but twenty tons to the acre is, for the most part, considered as a proper dressing. It is said to be frequently applied on the summer fallows for wheat, and sometimes as a preparation for barley; and may likewise be laid on clover or other leys, before they are ploughed down for grain crops, but in such cases so large a quantity is not requisite. When put upon grass-land, in not too large a proportion, it commonly produces great and sudden effects, the crops quickly becoming very luxuriant." And it is also observed, that such lands as have been treated in this way, when again brought into tillage, mostly produce abundant crops of the grain kind. It has been stated by Dr. Anderson, that "the effects of this sort of manure on the west coasts of the northern parts of the island have been very extraordinary, especially upon the heathy or mossy soils; and it is supposed that such kinds of sand are more common on the east coasts than has been generally supposed from the little attention that has been bestowed by the farmer in such situations to procure it for use."

Although common sand cannot be properly considered as a manure, it is often found useful in the stiff, clayey, and loamy soils, in lessening their tenacity, and rendering them more light and mellow. This substance has been laid upon rough pasture and meadow land, with the effect of rendering the surface more equal, and bringing up a close thick crop of grass with much white clover. In these cases, the quantity should be proportioned to the stiffness of the soils; but the best practice is, not to apply too large a dressing at a time, as injuries may be done where a very large portion is put on at one time.

Manures of the saline Kind.—There are various substances of this sort, when in combination with earthy and other ingredients which are found beneficial as manures in many instances, when properly employed. The materials that are principally made use of in this way are the refuse of different manufactures, such as those of bleaching and soap-boiling, where in sufficient quantities, as in the neighbourhood of large towns, and where such businesses are conducted on an extensive scale. The ashes which remain after the combustion of various green vegetable matters, wood, pit-coal, peat, &c. and some other substances, such as foot and sea-salt, are of the same nature. It is suggested in a late practical work, that "it is probably to the different alkaline principles contained in these substances, from the great facility and power which they possess of acting upon and dissolving the parts of animal and vegetable matters, especially such of the latter kind as have been rendered insoluble by the absorption of the oxygen, or pure air of the atmosphere, from long or frequent exposure to it, and even fossil coal, under similar circumstances, and by this means forming new saline compounds which are soluble, that their beneficial effects as manures are chiefly to be ascribed." And "that as such inert or insoluble vegetable or peaty matters, when decomposed or reduced into a state of solubility by alkaline substances, assume

a brownish-red colour, and become insipid; the alkalies, in such cases, must enter into combination, and be neutralized by the acid or acids contained in them, which will be found to be the phosphoric and the oxalic, or acid of sorrel; from which will be formed, according to the nature of the alkali contained in the substance made use of, phosphats and oxalats of potash, soda, or ammonia, which are matters capable of promoting the growth of plants." But, beside their forming in the soils, or the earthy materials with which they are mixed, such compounds as are beneficial in promoting the growth of vegetables, they may be useful in many cases, when properly applied, and used in sufficient quantity, in correcting the acidity, in altering the state or condition of the lands, as by taking away moisture from the surface where it prevails in an over-proportion in meadows and pastures, and thereby supports crops of coarse vegetables, and by rendering the texture of such grounds as are under the plough more open and mellow, consequently more suitable for the reception of the roots of grain, and other crops. But some of these materials, such as the bleacher's refuse, contains vegetable and mineral alkali, in such proportions as render it incapable of being made use of without being previously mixed with other materials. For which purpose, it is suggested, that "fresh mould or peat earth should be procured; and after having been well mixed and blended with it in the quantity of about eight or ten parts of the earth to one of the refuse, a proportion of rotten dung, suitable to the purpose for which the manure is intended, may be added, by which means a good manure will be formed." And the waste of soapers is another substance that may be made use of in the same way; but in this, it is observed, there is a considerable portion of lime mixed with the alkaline matter. The lees, or liquors, which are drawn off after making soap, as containing much alkaline saline matter, may likewise, where they can be procured in sufficient quantities, and at a reasonable rate, be made use of in a similar manner.

All these different substances, when combined with good rich vegetable mould, turf or peaty matters, and made use of as manure, are constantly found to be the most beneficial upon the stiff clayey and loamy soils; as in such sorts of land it is supposed that they probably not only contribute to the increase of the crops, by furnishing such soluble matters as can be readily taken up by their absorbent roots, but, by lessening their stiffness and tenacity, render them more proper for their reception."

In regard to the proportion or quantity of these manures which may be necessary, it must, as in other cases, vary according to the particular circumstances of the ground or soil upon which they are applied, and the views of the farmer in their application. But it is usual to apply them upon lands in a state of tillage, as well as under grass; in the first they are generally either put on in the state of compost, at the rate of about ten loads to the acre, just before the seed furrow is given or sown over the surface, and harrowed in with the grain; in whichever mode they may be applied, it is requisite to have them spread as equally as possible, in order that they may produce their effects in the most extensive and perfect manner." In the latter it is observed, that "though they may in some instances be used alone, it is probably a much better practice to have them mixed with such earthy substances as have been just mentioned before they are laid on the swards, as by such a practice their effects as manure may be rendered more complete and permanent. Upon grass lands they are often used to the amount of from one hundred to one hundred and fifty bushels. And most grass lands are improved by the application of such manures, but especially such as are wet, and disposed to the production

tion of coarse four vegetables, such as rushes, wild forrel, and various other plants of the same kind. But the ashes, or earthy saline matters, arising from the combustion of different fresh vegetable products, though beneficial as manures, are too wasteful and uneconomical in their production to be made use of, except in particular instances, as where wood and other vegetable productions are very abundant, and used commonly as fuel. Or where they cannot be readily cleared away by other more advantageous methods, as ten or fifteen parts, and in some cases considerably more, of such materials are dissipated and lost during the process. Where they are in sufficient quantities for this purpose, it is suggested that they may probably be employed to the greatest advantage by being mixed with a good portion of rich vegetable mould, or peat earth, and a quantity of well fermented dung; as, in such a compound state, they are capable of being applied more extensively, and at the same time in the most favourable condition for the support of vegetation. When made use of on the heavy soils, the quantity of ashes in the compost should be much greater than on those of the lighter kinds; they are, in general, the most effectual when applied as a top dressing to grass lands, especially such as are commonly termed four, or have much tendency to the production of moss on their surfaces." See ASHES.

And peat earth is another substance met with in different districts, which, after being cut and dried by the heat of the summer, is made use of as fuel. By the consumption of this sort of earth in this way, a considerable loss in respect to manure is sustained; as it has been found, that, "in many cases, nineteen parts out of twenty of the material are dissipated and carried away in the process of combustion, which, as it has been shewn, that the inert vegetable or peaty matter, produced by the action of oxygen, or the pure air of the atmosphere for a great length of time, is capable of being rendered soluble, by mixing lime in certain conditions with it, and still more effectually by alkaline saline substances, might have been preserved and rendered useful." However, in Berkshire it is the common practice to dig up peat earth, merely for the purpose of burning it into ashes, in order that it may be used as a manure upon land in various cases.

But as it is only from fresh or green vegetable productions that alkaline saline substances can be obtained when burned, none being afforded by the combustion of dead or decayed vegetable matters, it would seem that the ashes of peat earth seldom contain much saline matter. It has, however, been observed by some, that all peat earths afford alkaline saline matters in a greater or less proportion when burned, and that in some it is from a twenty-second to a thirty-second part of their weight. It is stated, that "the ashes produced from the burning of peat about Reading in Berkshire, which long experience has shewn to possess great fertilizing powers, are asserted to contain no alkaline salts, nor, from the hasty analysis of them which was made by lord Dundonald, was any saline matter, except a small proportion of sulphat of magnesia, or Epsom salt, found. But it is added, that "if the analysis had been more carefully made, and when the ashes were newly burnt, they would most probably have been found to contain a hepar of lime, which is a saline substance soluble in water, while gypsum, the substance to which it returns on being exposed to the air, is insoluble." The fertilizing effects of these ashes may, therefore, it is supposed, probably materially depend upon this hepar, a circumstance which is rendered still more probable from the observation of Mr. Middleton, in the Middlesex Report, that "the hills on each side of the meadows which produce the Newbury peat-ashes, consist of chalk, easily dissolvable by

heavy rain, which washes it off the ridges down the furrows, ditches, and streamlets, to the low grounds, where, mixing with the floods, it is floated over the meadows, and deposited in the peat. Consequently the peat of this district differs from that of most others, by the quantity of chalk which it contains; and, when dug, dried, and burnt, the fire reduces the chalk to lime, and the rest to ashes. Hence Newbury ashes are a mixture of lime and vegetable ashes; and it is very probable that any common peat-ashes, or the ashes of rough grass land, of turf, heath, furze, ling, wood, &c. produced by the operation of paring and burning, being mixed with chalk lime in due proportion, would be as equally fertilizing as these noted ashes." But it has been suggested, that there is another circumstance that may produce a difference in the saline and other substances contained in the ashes of different peaty earths, which is that of the presence of mineral springs. When, by this means, an over large portion of sulphat of iron, or green vitriol, happens to be present in the peat, the ashes produced from its combustion must in consequence become injurious, or at least much less beneficial to the growth of vegetables, than in cases where such a substance is not present. Its prejudicial effects, according to lord Dundonald, may be corrected by the use of either lime, magnesia, alkaline salts, or dung; but that preference is to be given to magnesia and alkaline saline substances, as they not only decompose the vitriolic salt, but form other saline substances, which are found favourable to vegetation or the growth of plants.

And where dung is made use of in such cases, the vitriolated iron is brought into its metallic condition, and the sulphuric acid, thus set at liberty, enters into combination with the ammonia or volatile alkali formed from the dung, and produces sulphat of ammonia; or, by uniting with the calcareous matter, and the additional assistance of the inflammable, or putrescent matter of the dung, it may be converted into a hepar that may be beneficial to the growth of plants as crops.

Ashes of these descriptions may be used as a manure, either by being harrowed in with the grain-crops, or sown over them as a top dressing after they have come up. In the former case it is advised, that they should be employed in a somewhat larger proportion than in the latter; in which "the best practice is to sow them over the crops before they are grown too high; and if the weather be rather inclined to wetness, it will be the more favourable: the quantities commonly employed in this way are from fifteen to twenty bushels the acre, according to the state or condition of the land. Where laid on grass lands, whether those of the artificial or natural pasture kinds, they often produce great improvements, rendering the grasses thicker, finer, and more close and abundant, often removing much of the mossy matter which infests them. See ASHES.

And peaty substances, in the reduced state of dust, are sometimes made use of with great benefit; but it is suggested by lord Dundonald, that this sort of earth may generally be employed to most advantage by being well mixed and incorporated with such substances as contain alkaline salts, or with alkaline hepars, or by a mixture of sulphat of soda with lime in its active state." It is likewise supposed, that the powdery or dusty matter of pit-coal might, probably, be applied with the same advantage if prepared in a similar manner, and it is capable of being rendered soluble in the same way. And it is further asserted by the same writer, "as the result of experimental trials, that the effects of peat earth, mixed and incorporated with alkaline saline substances, are equal, if not superior, to those from dung, the weight

of each being the same;" which, if it be well-founded, shews the superiority of employing peat earth in this way, instead of converting it into ashes, to be much more than has been already believed to be the case. See *PEAT-dust*.

And the ashes obtained from pit-coal, when applied as manures, are found to be useful in many respects; but it is supposed, as they can contain saline matter only in proportion to the quantity of fresh vegetable products that may have been consumed along with them, little of the effect which is produced can depend upon it; much more, probably, arises from the portion of calcareous earth which they contain. It is also added that "something, in many cases, probably depends on the animal substances that may have been occasionally burnt, or afterwards mixed with them, before they are made use of as a manure. And that "they may also be serviceable on the stiffer sorts of soil, by rendering them more open and disposed to admit the roots of growing vegetables." This "seems to be shewn by their utility in the stiff clayey grounds, from which brick earth has been dug, and on what are generally termed four lands. On the more tenacious loamy soils, they may operate by giving friability, and at the same time the calcareous principle, in a small degree, where it is deficient, which is further supported by their having been found from experience to be much less useful in the poorer sorts of land, than those that are of a good quality."

It may be noticed, that the application of these ashes to stiff soils, from which brick earth has been taken, renders it sufficiently friable to afford good crops of beans, a sort of plant which, though it grows well on heavy soils, could not be produced on lands so very stiff as the bottoms of brick grounds, without these ashes. However, except in such cases as the above, this manure is probably best adapted to grass land as a top-dressing, and it may be occasionally used in this way to young grain crops in particular cases.

With regard to the proportion in which it may be laid on, it must be different according to the views of the farmer, the nature of the crop, and the state of the ground, as well as other circumstances. See *Coal-ASHES*.

Another saline substance is met with in foot, that experience has shewn to be of much utility, when applied to land as a manure. It is probable, that the beneficial effects resulting from the use of this substance depend, in a great degree, on the quantity of alkaline saline matter which it contains; which by its action on the rich vegetable mould of the soil or earth with which it is blended, may render it more capable of supplying the nutrition of vegetables; and it may bring the gross oleaginous matter of the foot into such a state as to be capable of solution or diffusion in water, and in that way render it fit to be taken up by the absorbent roots of vegetables. It is supposed, that "the earthy matter of this substance, as well as that of different kinds of ashes, may probably be rendered more suitable for the purpose of promoting vegetation, by their having been exposed to the action of fire, as is well known to be the case with clay." The great state of fineness in which foot is found, may, likewise, it is supposed, be serviceable, as by that means it becomes capable of being more regularly and more extensively mixed with the soils on which it is applied. And it is believed, that "the good effects of most substances employed as top-dressings depend, in some measure, upon this circumstance." It is thought probable, that this substance, as containing alkaline salt in a considerable proportion, may probably be used with greater advantage by being well mixed or blended in rich mould, or peat-earth, and by such a method the quantity of manure would be

greatly increased. This should not, however, be attempted where the destruction of insects forms any part of the design of the farmer in its application upon his land.

Soot is a substance which is chiefly made use of as a top dressing to grain crops and grass lands. "On the former it has been found extremely useful in destroying the wire-worm and other destructive insects. This is probably effected by the bitter oleaginous liquid formed from the union of the alkali and the oil of the foot, impregnating those parts of the plants on which they feed, and thereby causing them to be rejected by such insects." It may also produce some advantage in this respect, by promoting a rapid vegetation, and thereby rendering the texture of the plants, very quickly, too firm to be preyed upon by them, as has been observed by lord Dundonald. That it is very powerful in promoting the vigorous growth of vegetable crops, is shewn "by the change which takes place after sowing it over such young wheat crops as have a yellowish sickly appearance, as they frequently put on, in a very short time afterwards, the healthy green aspect. On meadow and pasture lands, experience has likewise shewn it to be highly useful, not only by encouraging the growth of a finer sort of grass, but by destroying or correcting the frequent disposition of such grounds to produce moss, and some other coarse sorts of vegetable productions." In respect to the quantity or proportion that may be applied, this must vary according to the circumstances of the case; the most common quantity is generally from about forty to fifty bushels on the acre. See *SOOT*.

It is advised, where any of these or other materials that contain saline matters, are to be employed as manures, that "they should always be preserved in sheds, or other convenient places, from rains, or the accidental application of water to them, as where this practice is neglected, the saline substances are soon dissolved and carried away in a liquid form. It is chiefly from this cause, that substances of this kind, which have been long exposed without being covered, are often found so inferior in their effects to those which are fresh or newly made. On this account also, if such substances are laid on land at too early a period of the season, they will be liable to have much of their valuable properties carried away by the rains that may take place."

The muriat of soda, or sea-salt, is a substance, the utility of which has been already noticed, but which, "for the purposes of manure, seems not yet well ascertained, as by some it is considered as possessing considerable powers of promoting vegetation; while others have experienced little or no advantage from its application. But though it may prevent putrefaction when employed in large proportions by its antiseptic property, as has been shewn by different trials, when used in small quantities it has a tendency to promote the process. On this account, it may therefore, it is supposed, be serviceable when incorporated with farm-yard dung, and other animal or vegetable matters, in small portions."

The author of "Practical Agriculture" has suggested, that "as every where in the vicinity of the sea a ready means of obtaining this saline material in unlimited quantities offers itself, it may deserve more particularly the notice of the agriculturist; and more especially as many other substances that are known to contain, or be impregnated with it, such as the weed thrown up by the tides, and the sand over which they flow, can be easily procured."

There is still another substance of this nature, that "exists in the bittern, waste, or refuse of salt works, which generally contains muriat of magnesia in large proportions.

It has been found to possess very great septic qualities, and may, therefore, be highly beneficial when mixed with dung, or earthy matters. Experience has shewn it to be capable of promoting vegetation in a great degree.

The above writer thinks, that "in whatever manner substances of the saline kind may produce their effects in promoting vegetation, when employed as manures, it is evident, from their containing in themselves little or nothing of such matters as are capable of affording nourishment to plants, that they may, in most cases, be made use of to the greatest advantage, by being mixed and incorporated with such substances as they are capable of acting upon and reducing to a state proper for the support of vegetable crops; such as rich earthy materials, imperfectly reduced dung, and other matters of a similar kind. Where substances that contain the muriat of soda, or sea-salt, are employed, they may probably be applied to much advantage, by being mixed with imperfectly burnt clay, when reduced to the state of powder. And if upon trial they should be found effectual in this form, they may be very conveniently made use of in the way of top-dressings to grass or grain crops in the spring."

Manures of the mixed or compost Kinds.—It is extremely evident, from what has been stated and explained in respect to the nature of the different substances that are capable of being used as manures, that many of them may frequently be mixed and blended with each other, or with materials of other kinds, so as to be not only considerably increased in quantity, but often rendered more effectual and proper for application than in their simple states. At the same time, it is clear, that some of them may be thus mixed and incorporated with each other with much more benefit than others; for although the constant experience of farmers has decidedly shewn the great importance and advantage of employing composts, till lately they have paid little regard to the mixing together of such matters as are, from the principles which they originally contain, or which are formed from them, in the changes which they undergo in the different stages of their decomposition, adapted to act in the most suitable manner for producing such combinations or alterations in the materials, as are capable of being beneficial in the greatest possible degree in promoting vegetation, when applied to the land or soil.

It is obvious, that the manure raised in the farm-yard is the most common application of any, and which, from its being formed by the gradual decay of various kinds of vegetable matters, as hay, straw, fern, and various other materials of a similar nature, with which the dung and urine of animals is incorporated and combined, it is to be considered as a compound manure. And from the largeness of the proportion in which such vegetable productions enter into its composition, and the quantity of earthy materials that is in most cases added, especially where the management is judicious, by laying of suitable foundations or bottoms, it is less frequently requisite to blend it with other substances than most other manures. But as most of the vegetable materials that constitute the chief part of it are made use of in a dry and hard state, and do not so quickly ferment or run into the state of decay, notwithstanding the quantity of animalized matters that may be blended with them; it becomes useful to turn them over once or oftener, in order that their complete putrefaction may be promoted, and at the same time the different materials minutely blended together. And it has been suggested, that "in forming of this manure, care should also be constantly taken, that the heaps be so situated, as that they may not become too dry, or too much soaked in water, as in either case they

must be greatly injured," and that "whenever it may be requisite to incorporate any earthy material with this sort of manure, the agricultor should carefully attend to the state or richness in which it may exist in the yard, and proportion such additions accordingly." It cannot, however, ever demand a portion nearly so large as that of such manures as are almost wholly composed of animal substances of such earthy matters.

After observing that straw or litter is the basis of farm-yard manure, or what is often termed dung, a late writer suggests that, for light and heavy soils, the dung should be prepared in different ways, be used at different seasons, and applied to different crops. For light soils, he thinks, manure requires to be much higher prepared than is necessary for clayey soils; and that every step of the previous preparation, to be perfect, ought to be executed in a quite different manner. "For soils of the first description, where turnips are taken as a first crop, dung can hardly be too well prepared; because the nature of the crop, to which it is applied, renders a complete incorporation with the ground absolutely necessary, without which the young plants might be starved at their very entrance into life. In the best farmed English counties, which have come under his observation, dung is often kept over year, in order that it may be perfectly rotted: and the late Mr. Bakewell was in habits of not applying it till it was reduced to a state something like black snuff." He does not, however, approve of such protraction; for, when the preparatory steps are conducted with judgment, there is rarely any necessity for keeping dung over year upon turnip-farms; besides, such a delay causes a waste of the article, and most likely dissipates its strength: at all events, a year's interest of the value of the increased produce must be lost. In general cases, there is not much difficulty in preparing dung upon turnip-farms; because, in the driest season, from the nature of the food used, such a quantity of liquid passes from the animals, as to prevent burning, provincially *fire-fanging*, the greatest obstacle to the rotting of dung that can be experienced. If turnip dung is regularly removed; if it is properly mixed with the horse litter, and other excrementitious matter accumulated upon the farm, it will be found an easy task to prepare all that is made by the middle of April, at which time the fold-yard should be cleared. What is produced after that time should be stored up separately, receive waterings, if the weather is dry, and be reserved for clover stubbles, or other fields that are to be dunged in autumn." But though the middle of April is mentioned "as a good time for clearing the fold-yard, this does not prevent the work from going partially forward through the winter, when suitable opportunities occur. When drove out of the fold-yard, the dung should be laid up in a regular heap or pile, not exceeding six quarters, or four feet and one half in height: and care should be taken not to put either horse or cart upon it, which is easily avoided by backing the cart to the pile, and laying the dung compactly together, with a grepe or fork. It is also useful to face up the extremities with earth, which keeps in the moisture, and prevents the sun and wind from doing injury. Perhaps a small quantity of earth strewed upon the top might also prove useful. Dung, when managed in this manner, generally ferments very rapidly: but if it is discovered to be in a backward state, a complete turn over, about the first of May, when the weather becomes warm, will quicken the process; and the better it is shaken asunder, the sooner will the end in view be gained." A secluded spot of ground, not much exposed to wind, and perfectly secure from being flooded with water, ought always to be chosen for the scite of such

piles or heaps. If the field, to which it is to be applied, is at hand, a little after-trouble may be saved, by depositing it there, in the first instance; but he has always found it most convenient to preserve a piece of ground, adjacent to the home-stead, for such a purpose. There it is always under the farmer's eye; and a greater quantity can be moved in a shorter time, than when the situation is more distant. Besides, in wet weather, and this is generally the time chosen for such an operation, not only are roads cut up, by driving to a distance, but the field, on which the heap is made, may be poached and injured considerably." This he conceives to be "the most approved method of procuring dung upon turnip or light farms."

However, "upon clay soils, where wheat forms a principal part of the crop; where great quantities of beans are cultivated, and few turnips sown, unless for the use of milch cows, the rotting of dung is not only a troublesome, but an expensive affair. Independent of what is consumed by the ordinary farm-stock, the overplus of the straw must somehow or another be rotted, by lean cattle kept in the fold-yards, who either receive the straw in racks, or it is thrown across the yard, to be eaten and trod down by them. According to this mode of consumption, it is evident that a still greater necessity arises for a frequent removal of this *unmade* dung; otherwise, from the trampling of the beasts, and the usual want of moisture, it would compress so much as to prevent putrefaction altogether. To prepare dung sufficiently upon farms of this description is at all times an arduous task, but scarcely practicable in dry seasons: for if it once gets burnt (*fire-fanged*), it is almost physically impossible to bring it into a suitable state of preparation afterwards; and, at all events, its virtues are thereby considerably diminished. The straw flung out in considerable portions to the fold-yard, after being compressed by the trampling of cattle, becomes rather like a well-packed stack, than a mass of dung in a preparatory state. The small quantity of water and dung made by the animals is barely sufficient to cause a slight fermentation; and this fermentation, when the heaps get into a compressed state, is sure to bring on the injury of *fire-fanging*. To prevent such an injury, no measure can, it is conceived, be so successfully used, as a frequent removal of this unmade dung, especially if the weather is wet at the time. If people can stand out to work, you cannot have too much wetness when executing this operation; for there is always such a quantity of the straw, that has not passed through the entrails of the cattle, as renders it almost impossible to do injury, in the first instance, by an access of moisture. What he would therefore recommend, upon every clay-land farm, especially those of considerable size, is a frequent clearing of the fold-yard; and that the greatest care should be taken to mix the stable or horse-dung in a regular way with what is gathered in the fold-yard, or made by other animals, in order that a regular heat or fermentation may be speedily produced. Where the materials consist of a small quantity of dung, or excrementitious matter, and a large store of unrotten straw, only partially moistened, he is clear that no damage can ensue from putting horses and carts upon the heap; nay, he rather thinks that a positive benefit will be gained from this slight compression. He is, however, at the same time, well aware that the sentiments of many able and judicious farmers are different from his on this point; they being of opinion, that the natural pressure of the materials is quite sufficient, and that any more is attended with injurious consequences. He is, however, satisfied, that such ideas are unfounded; having tried both methods upon an extensive scale, and, from the results, feels himself justified in recommending the manage-

ment. Perhaps this difference of sentiment may arise from not attending to the very different qualities of dung on different farms; for he has already fully recognised the propriety of abtaining from putting horses and carts upon such heaps or piles, containing materials which can be called dung, even though it may be in an unripe state. He contends, however, that no injury is sustained in slightly compressing a mass of rough materials; nay, that such is attended with beneficial effects: for, if the materials were laid up with a fork, or a grepe, as is recommended in the case of turnip or half rotten dung, the small portion of moisture therein contained would speedily be wasted or evaporated; a circumstance which he has repeatedly witnessed, especially when dry weather succeeded the period when the heap was made up. Besides, driving a one-horse cart over the surface of materials, only one stage removed from the condition of dry straw, will never prevent fermentation. If left in the fold-yard, he grants that the constant treading of the cattle therein confined, and the daily increased weight of the heap, would undoubtedly produce that evil; but such is effectually prevented by frequent removals, especially if rainy weather prevails at the time. The heap or pile, as in the former case, should be formed in a secluded spot, if such can be got at hand; because the less it is exposed to the influence of the sun and wind, so much faster will fermentation proceed. It should be constructed on a broad basis, which lessens the bounds of the extremities; and several separate heaps are necessary, so as too much may not be deposited at once, which, to a certain extent, would bring on the very evil he has been endeavouring to avert. By shifting the scene frequently, and allowing each covering or coat to settle and ferment, before laying on any more, the most happy effects will follow; and these heaps (all such as are completed before the first of May) may reasonably be expected to be in a fit condition for applying to the summer fallow fields, in the end of July or first of August. If the external parts get dry at any time during the process, it is proper to water them thoroughly, and, in many cases, to turn over the heap completely. He may add, that he has repeatedly experienced great advantage from laying a thick coat of snow upon such heaps, as, by the gradual melting thereof, the whole moisture is absorbed, and a strong fermentation immediately follows. He would continue the same method of management during the summer months, so far as circumstances permitted; though it rarely happens that dung collected at this advanced period is fit for use in the same season, unless it be such as is made by keeping horses or cattle in the house, upon green food. Perhaps, as a general principle, it is proper to thrash out all grain before summer arrives, (a small quantity for litter and other purposes excepted,) in order that the full value of the raw materials, when converted into manure, may be gained. Straw thrashed in the summer months always wants a good deal of its original strength; it is broken and hashed by the mills, therefore a large portion must at once be thrown to the fold-yard, where its strength is still more exhausted and dissipated. Even when stacked carefully, it will be found, next winter, to produce much less bulk of dung, than if it had been used at the proper time; and interest of the amount for one year is lost; all which things, added together, will be found equal to one-half of the original worth."

It may be observed that in cases where animal matters are thrown together in any quantity, a great increase of good manure may be made by combining with them, as already mentioned, rich surface mould, peat earth, or the scrapings of old ditches and roads; as in this way the ammonia formed during the decomposition of the animal materials is prevented

vented from escaping, as would otherwise be the case, and which, by combining with and acting upon the earthy materials, quickly renders them proper for the purposes of manure. And as substances of the animal kind have been found to run very rapidly into the state of putrefaction, it has been remarked, that "they may frequently be incorporated with such vegetable materials as are little disposed, or with difficulty made, to rot or become putrid, and by such means good composts be more expeditiously formed. In making use of such earthy materials, it may be of much advantage to have them exposed to the influence of the atmosphere for a considerable length of time, frequently turning them over, before they are mixed with the manures, as by such means they become in a more pulverized state, and are capable of being more intimately blended with such materials, and afterwards spread over the land with much greater equality, a circumstance upon which their effects very much depend. And that when, in performing this business, the earthy substances are formed into a sort of ridge, about five or six feet in height, and nearly the same breadth in the bottom, they will be in the most proper situation for being united with dung or other matters that may be intended to be blended with them."

By a late writer it has been remarked, that "lime is a substance that has often been too indiscriminately made use of in the formation of composts, but which, by attending to the following circumstances, may admit of being employed extensively and with more beneficial effects. Where the destruction or decay of green or fresh vegetable matters, especially those of the more coarse and hard kinds, is intended, it should be used in its caustic state in small quantities; as in this condition, thus sparingly employed, it reduces more expeditiously the ligneous and hard parts of such matters to an earthy state; and as, during its action in this way on these substances, such elastic matters are set at liberty, as by their subsequent combination afford ammonia or volatile alkali, it may frequently be a beneficial practice to blend such earthy substances as have been just mentioned with them, and thereby prevent the elastic matters from being dissipated and lost. If a portion of rich farm-yard dung be some time afterwards incorporated with the materials, a valuable compost will be formed." And it is added, that "quick lime is likewise found useful, sometimes in bringing the hard parts of dead vegetable matters, as tanners' bark, fern, straw, cabbage-stalks, leaves, &c. quickly into the state of earth or mould; but whenever it is made use of in this way, it should be had recourse to only in a very scanty proportion to those of the matters with which it is mixed, as when it is employed in large proportions, it is liable, from the heat that is extricated or disengaged by its combining with the moisture of such substance, being so augmented during its slaking, as to convert them into a coaly substance that is insoluble, and at the same time to force off, in the form of gas, their elastic principles, except such a quantity of carbonic acid as may combine with the lime during the process."

It is evident that, "by the common practice of blending quick or caustic lime with farm-yard dung, much loss is frequently sustained; as by its violent operation upon such substances, some of the elastic matters are not only set at liberty and quickly conveyed into the atmosphere, but, with what remains insoluble saline, compounds are formed which cannot assist vegetation. It is conceived that the complete putrefaction of such manures, when necessary, is best promoted by the use of lime in its mild state. But in cases where it is "to be blended with peat or earth, the most advantageous method is to use such lime as has been newly made and well slaked, in the proportion of about one part of the lime

to five or six parts of the peat or mould, which should not be too much calcinated, or dried, before it be made use of. By this means the heat which is generated will not be sufficient to produce any injurious consequences, either by forming a coaly matter, or forcing off the elastic principles in the state of gas. And the volatile alkali, which is composed in such cases, by being allowed to enter into combination, as it is formed, with that part of the peat or mould which has not been acted upon by the lime, in consequence of its being employed in so small a proportion, and in its effete state, will form a soluble saline substance, capable of promoting vegetation."

Lord Dundonald states, that there "are other substances that may be still more beneficially employed in forming composts with peat earths, when they can be procured in such quantities and at such cheap rates as render them capable of being made use of in this way," such as "alkaline saline matters, or such substances as contain them in any quantity; as by mixing these with the peaty materials as above, they are made perfectly soluble, while by the use of lime only, such a proportion of them is rendered soluble, as can be acted upon by the quantity of ammonia or volatile alkali formed during the time it is mixed with them." And still farther, that insoluble compounds, such as have been noticed, are formed in the latter circumstance.

But the practice common, in different districts, of making composts with lime and mould on the headlands, or other parts of the fields on which they are to be applied, which cannot be done to advantage, except where the surface mould is rich in vegetable matter, is not to be much recommended, but wherever such composts are to be formed, the land should always be ploughed or dug up to a great depth, and be reduced into as perfect a powdery state as possible; fresh lime may then be deposited in small heaps, along the middle ridge of the headland, and the earth in this fine state be thrown over them, in the proportion of about four parts of earth to one of lime, being kept close by being beaten down with the back of the spade. It is observed, that from the gradual slaking of the lime in this situation, by the moisture of the earth, elastic matters are set at liberty, which combining with the mould or earth, render it still further reduced, and by being afterwards very intimately blended by means of the spade with the very fine particles of the lime caused by the slaking, a valuable compost is made for the stiffer sorts of soil, especially if a small quantity of good rotten dung be well incorporated with them some time afterwards.

Although farm-yard manure is seldom in a state to admit much addition of earthy matter, yet where there is much liquid oozing from such composts, or stagnating about the bottoms of them, some of the earthy materials which have been mentioned may be laid around them in order to absorb or take it up, and prevent the great waste that must otherwise take place, as may often be observed in the situations where dung composts are made. And it is advised, that "this should be more particularly attended to, where such composts are laid in situations that have not been properly formed as dung-heads." In such cases, it may often be an useful practice to place a considerable thickness of such materials in the bottoms, before the farm-yard compost is carried out, and laid upon them, as by that means the manure heap may be greatly increased, and at the same time a proper substance for the volatile alkali contained in such liquors to act upon supplied. This method is fully confirmed by the practice being in use wherever any attention is directed to economy in the forming manures of this kind.

With regard to the application of this sort of manure, the nature of the soil, the state or condition of the land,

and

MANURE.

and the goodness of the matters, are circumstances which render a difference in the quantity of such manures necessary. The heavy sorts of soil, such as those of a clayey or deep loamy nature, require composts constituted of the lighter sorts of earthy materials; while the thinner and more light sorts stand in need of those which are formed of clayey, loamy, or the more tenacious matters. But "in general, the allowance of such manures should be from sixteen to twenty loads to the statute acre, each containing seventeen or eighteen hundred weight. On many occasions, however, a much larger proportion may be required, and in others a less may answer the intentions of the farmer." It is added, that "the mixture of dung and litter, and other materials which are gradually collected and formed into heaps in the farm-yard, is, in general, when employed without having any other substances incorporated with it, laid on such lands as are under preparation for wheat, turnip, or barley crops. It is likewise in some places laid on for a pea crop, where what is intended to be the succeeding crop."

The compost manures, which are collected from the streets of large towns, are formed of a great variety of substances, as the recrements of decayed vegetables, putrid animal matters, and ashes; but from their abounding for the most part with substances of the latter kinds, they may, on the principles just stated, be in many instances greatly increased by having rich surface mould or peat earth blended with them; and by such a practice, where the manure heaps are in a condition to admit of it, the risk of waste by the escape or dissipation of their more fluid contents in the aerial or gaseous state be effectually prevented. But such additions can only be advantageously made where the proportion of animalized materials in the manure is large; in other cases it is better to employ them in the state in which they are met with when collected.

It is found that compost manures are capable of being used with great benefit on different soils, and in preparation for different sorts of grain crops, as well as those of the grass kind. It is stated, that "when applied in the proportion of fifteen or twenty tons to the acre, they generally produce great fertility. They should, however, be applied according to the particular circumstances of the soils, and the nature of the crops for which they are made use of."

It may be noticed, that the result of practical trials fully proves that the most beneficial composts are all those which are formed by the combination of earthy materials with animal matters. See COMPOST.

Manures, Means of increasing and preserving them.—After what has been already advanced, the best means of augmenting, preserving, and managing manures may be considered, as upon this in a great measure depends the general fertility of farms, and the goodness of the crops that are raised upon them. It is of course a matter of great interest and importance to the farmer to see that nothing is destroyed, wasted, or thrown away, that can in any way be converted to this purpose. It has been remarked by a late writer, "that there are many substances that may be rendered useful in this way, which have hitherto been little regarded by the cultivators of land, there can be little doubt, when the daily waste of animal, vegetable, and other matters that take place in every country, from their being carried away by rivers, or consumed by fires, is fully considered." By greater attention to the cutting of grain, so as to preserve as much straw as possible, as well as care in getting together the stubble, in many instances vast advantage may be gained in this view. And that "another great cause of loss in the production of manures is from the want of adopt-

ing or putting in practice such modes of management, in respect to different substances, as are capable of rendering them fit for the purpose of application in the most quick and expeditious manner; for it is obvious, that if by properly attending to such means, the same quantity of manure can be prepared in a short space of time, which under other circumstances must have required a long one, much increase of manure may be effected, and consequently great advantages be gained by the cultivators of the ground." It is stated, that what is necessary to be done in order to facilitate and hasten the decomposition and reduction of different materials into the proper states for being applied to the soil are, as has been seen, "in some measure, the free admission of atmospheric air, a quantity of moisture suited to the condition of the matters made use of, and a due degree of heat. And also the proper blending of animal with vegetable substances, in the incipient stages, and the addition of the lime, according to circumstances, and in proportions suited to the state and nature of the ingredients."

And in this intention, it is observed by the same author, "as the principal resource, on most farms, is the farm-yard, it should be constructed in such a manner, as that every thing may with ease and facility be converted to the purpose. In general one dung-heap may be sufficient; but where the size of the farm is large two or more may be necessary, as the putrefaction of such heaps proceeds with greater regularity and expedition, from the access of air and moisture being more free when they are not made too large; and, besides, they can be more conveniently turned over or removed. The parts of the yard on which they are situated should, while they are convenient for depositing the dung, and other matters from the sheds and other offices, upon, be neither too much elevated, so as to cause the dung to become dry, nor so greatly depressed as to favour the stagnation of water upon it, and thereby deprive it of the properties most essential to the promotion of vegetation. Before each of the dung-heaps a reservoir or basin ought to be made, into which not only the drainings from all the different sheds and places where animals are fed or kept may empty themselves, but likewise the urine from the necessaries, the fuds from the wash-houses, and the washings of the various utensils employed in the family. Without these advantages in the construction of farm-yards, much loss of manure must daily occur from the liquid matters of such places continually running away, and being otherways wasted, as well as from their not being made use of to forward the conversion of other substances into the condition of manures." But that, where these and other suitable accommodations have been provided, the farmer will have little more to do than "be careful in saving or providing such matters as are suitable for the purpose, and causing them to be properly placed and removed, in order to have them speedily reduced into the state of manure, and the quantity of his dung-heaps thereby greatly increased and extended. With the same design, various vegetable matters, such as hay, straw, fern, leaves, rushes, coarse grasses, flags, and many other aquatic plants, should be collected and preserved in as large quantities as possible, by allowing nothing of the kind to be sold or carried from farms, except in some particular instances, as where they are situated near large cities or towns, where such articles can be advantageously disposed of for the purpose of feeding and littering horses, or other animals, and at the same time an equivalent in good manure be brought back to the farm; by mowing and raking together the wheat or other stubbles, the fern from the commons, and leaves where they can be obtained, as in the vicinity of parks and other wood-lands, and by cutting the coarse grasses
and

and aquatic vegetables at such periods as they are in the most juicy and succulent states. The whole, after being sufficiently dried, should be carried to the farm-yards, and stacked up in convenient situations, either in or near them, for the purpose of being made use of as litter, and by that means being converted into manure. And in addition to these means, every leisure opportunity should be taken, before the commencement of the foddering season, to bring into the farm-yards such quantities of peat or boggy earth, rich surface mould, marl, dry mud from ponds or ditches, scrapings of roads, loam, and other substances of the same kind, as can be conveniently obtained, for the purpose of being applied as bottoms for the absorption of the liquid matters."

It is farther stated, that when such materials as are necessary have been thus procured, "the best mode of proceeding seems to be that of covering the whole of the yards where the cattle stand and tread, and even the pig-sties, in some cases, with layers of these earthy matters, eight, ten, or more inches thick, according to the number of cattle and other circumstances; and also to deposit in the reservoirs before the dung-steads proper quantities of the same substances, for the liquid matters which come into them to act upon. Upon these earthy bottoms, at the time the cattle are confined, pretty thick litterings of one or more of the materials that have been collected and stacked up may be placed, and the stables, cow and ox-stalls, pig-sties, &c. cleaned out upon them. Where it is the practice to tie up and confine the cattle in the night-time, the straw or other substances, after having been broken down and reduced by littering them, may be used for covering the bottoms of the yards, by which means their decay may probably be rendered more quick and convenient. It appears also probable, that where stubble, fern, rushes, leaves, or other vegetable matters, the textures of which are hard and ligneous, are employed, their decay or reduction into the state of manure may be greatly expedited by means of a slight portion of lime, in its active state, being spread over the earthy bottoms before they are applied, as has been found to be the case with tanners' bark." And that, "where the matters made use of in the way of manures are liable to be rendered too dry by the weather, their putrefaction and decay may be much promoted, by having them sprinkled over occasionally with water, which may be conveniently and readily performed by having a pump with troughs fixed properly for the purpose; or where these are wanting, from a pond in the yard." And in order "to render the plan the most effectual it is capable of, the whole of the cattle should be strictly confined to the fold or foddering yards during the winter, and not turned out, as is frequently the case, into the pastures, by which the making of much manure is prevented, great injury in many situations done to the grass-lands, and the flock, from being much exposed to cold and other causes, benefited in a far less degree than is commonly imagined. By pursuing this method, from the great consumption of straw and the coarser sorts of food by the young lean cattle, and of hay and luxuriant vegetable roots of plants by the others, such quantities of animalized matters are voided, as by mixing with the bottoms of the yards hinders their putrefaction, and affords not only an immense increase of manure, but of such as is of a very valuable kind. If there be not a sufficient proportion of animal dung and urine incorporated with the other matters, which can seldom be the case where the cattle are not regularly confined to the fold-yards, the manure, though it may be nearly as large in quantity, is found by experience to be very inferior in its effects when applied to

land." It is likewise stated, that "where the number of cattle confined in the fold-yards is great, it may be necessary, occasionally, to remove the bottoms, and the matters littered upon them, to the dung-steads, after they have become in some degree manures, by being well saturated and blended with the urine and other animalized matters. These must be immediately replaced by others in the way just noticed. And farther, "the earthy substances from the reservoirs should also be occasionally emptied out upon the dung heaps, and replaced by quantities of fresh materials of the same kinds, and the items of different gross vegetable products from gardens or other places."

Besides, "at the close of the season, when the cattle are turned out of the yards, the heaps of manure which have been thus collected and thrown together, should be turned over, in order that the animalized matters may thereby not only be still more intimately incorporated with the earthy substances, but, likewise, that more of the pure air of the atmosphere may be retained among the clods, from their being rendered much smaller by such means, and the putrefactive process be thereby more perfectly produced." And, "after this business has been well performed, as little delay as possible should be suffered to take place before the manure is applied to the soil; as, from the combination of oxygen or pure air with the carbonaceous material of the dung, and of azote with hydrogen, under these circumstances, such fluid matters are formed as constitute its most beneficial properties, but which are afterwards continually wasting, so long as it remains unapplied to the ground or soil." Hence, "on these accounts, as well as those which have been already stated, manure heaps should not be made too large, but of such sizes only as that they can be expeditiously turned over, and put upon the land. And another advantage which attends the having different heaps, and their not being large, is, that one can be prepared and carried away at a time, without the other's being in the least injured by any delay that may happen from unforeseen causes of any kind."

It is noticed in an useful periodical work, that "in many situations where the above-mentioned articles are plentiful, they are suffered to go to waste, though they may be used to great advantage for littering the stables and fold-yards. Ferns and rushes do not rot so soon as straw, but make a rich manure, and if well turned over in the spring, are sufficiently rotten in June." In winter and spring, when dung is taken from the stable or fold-yards to the fields, it is conceived better to throw it up with forks than allow the carts to be taken upon the dung-hills, a practice which prevents a speedy or complete fermentation. At these times, the quantity of manure may be much increased by mixing with the dung large quantities of rich earth, taken from old dykes, sediments of ponds formed by running water, and such other places as were most likely to afford it, well mixed with fresh or dissolved vegetable matter." But it is well observed, that the practice of mixing earth with dung requires to be managed with a delicate hand, especially in forming a dung-hill with materials that have not been previously subjected to fermentation, for, as in carting upon it, by pressing and consolidating the mass, it greatly retards, and, in some instances, almost entirely prevents, fermentation; indeed, by mixing any considerable quantity of soil with dung in an unfermented state, by pressing the straw and other matters into a small space, it so effectually excludes the air, that the dung, at the distance of several months, is found in a state very little different from what it was when put in the heap; and, after all, when it is in common language said to be rotten, it is, upon examination, found to be only decayed, and the produce, in place of abounding in rich mucilaginous substances,

substances, which all well-fermented dung does, is found to consist almost entirely of vegetable earth. There is, however, it is said, a mode of applying earth to dung-hills, that is not only safe, but highly beneficial: "It consists in covering the whole surface of the dung-hill lightly, either with common earth or broken peat, every time the stables or fold-yards are emptied; a covering of that kind not being heavy enough to press materially upon the mass, does not retard the fermentation, and has the great additional advantage of preventing the loss daily sustained about most farms by evaporation, and the dissipation of the greatest part of the valuable gases generated during the process of fermentation, all of which are entangled and retained by the earth; which, by that means, not only acquires high fertilizing powers, but renders the dung more valuable." And that "when a proper system is followed of carrying out the manure from the stables and yard to the dung-hill—as once a month, if it is spread equally over the whole, and a covering of the kind just mentioned laid above it, a considerable addition may be made to the quantity of manure upon every farm yearly, not only without risk, but with very great advantage." This sort of manure has been found upon light gravelly hills, or fertile clays, particularly useful. It is supposed that "the rich earth alone would no doubt have very much improved such ground, but by being mixed with dung, it probably became impregnated with something of a fertilizing nature, which would otherwise have been lost." In some cases, "instead of mixing as above, the earth has been occasionally laid on a foot or two deep, as a foundation to build dung-hills upon; at other times in situations where the drainings of fold-yards, or the urine of fat cattle, could easily be conveyed into it, and no doubt considerable advantages may be reaped from these methods of increasing the quantity of manure. In regard to the propriety of using rotten or rank dung, the latter is supposed very improper management, though pursued by some farmers, who do not wish to hasten putrefaction by leading out and turning, not only because these operations are troublesome and expensive, but because they believe that the quantity of dung is thereby lessened. They certainly lessen the bulk, but probably not the quantity of good manure. Perhaps they prevent the loss of some very fertilizing particles, which are exhaled by the solar heat, or otherwise injured by the weather, when the dung is applied in its rough state, and consequently not properly covered in. There can, however, be no doubt of a small quantity of rotten dung making land more productive than a much larger one of such as is rough or half rotten.

And it is believed that, "by mixing lime with manures composed of earth, and dung in the more advanced stages of their preparation, some increase of quantity may likewise be produced; and at the same time, by its uniting with the nitrous acid during its formation, may prevent that substance being thrown off into the atmosphere in a gaseous form, or readily washed down from the composts by rains; and thereby preserve a material that has long been found useful in promoting the growth of plants."

As great waste of manure is continually taking place from the evaporation of the more liquid parts of manure heaps, where they are much exposed to the influence of the sun or winds, and the washings of the rains, it would tend greatly to the saving of such matters, and at the same time considerably promote their complete putrefaction and decay, to have them placed in situations that are much shaded by trees or other means. It is suggested, that, in farm-yards, moveable coverings of some light kind of material might probably be highly advantageous for this purpose. By means of this nature, the manure heaps, in such places, may be effectually

screened from the action of the sun in the summer, and prevented from being injured by the heavy rain or snow that falls in the winter season. And as a further inducement to adopt such methods, the manures which have been preserved from the effects of the weather in this way, are said to have been found, by practical trials, to be far more efficacious in promoting the growth of crops, than under other circumstances; and of course capable of going much further in their application to soils.

In order to procure manure from the articles of food and other matters produced on the farm, different modes have been pursued in different situations. Some have strenuously contended, that the most advantageous plan is to have the whole of the hay and straw consumed by the different animals, without employing any of them in the way of litter, floors or standings for them being constructed in such a manner, as that they can be tied up, and kept clean and dry merely by sweeping, without being littered with straw or other similar materials; while others maintain, on the ground of actual experience, that the method of eating the hay by the stock, and employing the whole of the straw, as well as other matters, in the way of litter, is by much the most certain and effectual in promoting the increase of manure. On these different opinions, it has been observed, that "though each of the methods may be practised with more or less advantage, according to the nature of the farms;—as where there is much grass and little tillage land, the former may be preferable; but where the quantity of grass is small, and that of arable ground large, the latter;—it is probable, that a judicious combination of both may be the most beneficial, especially where, in addition to the common articles, coarse vegetable and rich earthy matters are provided, and made use of in the way which has been mentioned, as by such a combination the full effect can only be produced. In the former method, the loss by means of digestion and animalization is probably much greater than has been generally supposed by those who have maintained the superior utility of the practice."

In the soiling of horses, and different kinds of cattle, with rich green food, as clover, lucern, summer tares, and other artificial grasses, cut fresh every day during the summer season, and placed in cribs in the sheds or foddering-yards, the bottoms or floorings of which have been prepared and strewed with earthy materials and litter, in the manner already directed, there is another way of making great additions to dung-hills, as the evacuations of cattle fed in this way are very considerable. The earl of Dundonald has suggested, "that experience only can teach or warrant the belief of how few acres of ground, under the culture of artificial grasses, when cut green, and daily given to working horses and other cattle, will suffice for their maintenance. The artificial grasses, or plants best adapted to this purpose, are, he supposes, red clover, tares, and saintfoin. None of those succulent plants with large stems and leaves answer so well to be depastured as to be mown; not only on account of the injury they receive in being bruised by the treading of cattle, but, by being constantly cropped and kept short, they are deprived of the nourishment which they principally receive by their stems and leaves. Saintfoin is, he thinks, best suited to chalky or dry soils, and to the southern parts of Britain. It has often been tried without success in the northern parts of England and Scotland. Winter tares have also been sown, but have not been found to answer any valuable purpose. Clover and summer tares, therefore, should be the only plants of which the cultivation on a large scale should in these parts be attempted; and every prudent farmer will take care to have a full supply of them, as in the event

event of a superabundant quantity for green food, these crops are equally proper for hay. Tares should always accompany the culture of clover, to supply the deficiency of herbage between the first and second cuttings of the clover."

And "the quantity of manure that may be formed in this way is, probably, much greater than can be supposed by those who have not actually made a trial of the method. By some French writers it is stated, that from three to four hundred sheep, kept in this mode, manure sufficient for nearly an acre of land may be daily procured; and the manures, thus obtained, are likewise asserted to be preferable to dung procured in the common method." It has likewise the advantage of preventing the great waste that unavoidably must take place in feeding off such crops, and of bringing the whole of them immediately into use: besides, the manure, thus produced, becomes of a superior quality, from the vast quantities of worms and other insects that are generated during the hot summer weather, where it is going on to any great extent.

And the author of "Practical Agriculture" states, that "by means of covered sheep-folds, a great increase might also be made annually to the stock of manure. If this neglected, but highly beneficial, practice were regularly employed here, as is the case in many other countries, by having proper sheds and inclosures for the purpose, constructed of any slight materials near to the fold-yards, or other more convenient places of the farm, so that the sheep might have fresh air, and sufficient liberty to run about, and, at the same time, have the means of being sheltered from rain, snow, and the coldness of the winter season, the advantage to the stock would likewise be considerable, besides the great supply of manure that must be provided. In order to promote the latter advantage, the bottoms or floorings of such sheds and inclosures should be covered with such earthy materials as have been recommended for the cattle yards, and also littered upon in the same manner; all of which ought to be removed and cleared away to a heap, or the common dung-steads of the farm-yards, as often as they become perfectly saturated and blended with the dung and urine of the sheep, and fresh materials of the same kind supplied. In bad weather, it will be advantageous to keep them constantly in the covered folds, and feed them with hay in standing racks; but when it is fine, they may be suffered to go into the pastures in the day-time, and only be put into the folds during the night." It is added, that "the practice of keeping sheep in covered folds is made use of in Flanders, for the purpose of raising manures, with great success; and very dry sand is sometimes employed for the bottom of the folds, instead of litter." And that, "where the house-lamb system is carried on to any extent, the preparing and littering of the sheds and yards, into which the ewes are occasionally put, and the lambs kept and suckled, might be practised with great advantage, in respect to the production of manure; as animals, under such kinds of management, are constantly found to void urine and dung in much larger quantities than in the ordinary courses of feeding." Where deer are kept, the same management may likewise take place, and much good dung be raised. See *Sheep-FOLD*.

The ploughing down of full rich green crops of different kinds, in their most succulent states, is also another means of increasing manure, that may occasionally be adopted with great advantage.

And the practice of feeding off different green crops on the land by sheep, bullocks, or other animals, is another method by which much fertility may occasionally be given

to the soil at a cheap rate, as the expence of carriage is prevented, and a considerable saving of manure effected. Mr. Middleton states, that, by this mode of management, the great loss of urine and dung, that unavoidably occurs in the other methods, may be most effectually prevented; "for in the stables, cow-houses, sheds, fold-yards, and dung-hills, even under the best management, there is a great waste, perhaps of half, including dung and urine: under ordinary management, three parts of this manure is lost; but in the soiling of tares, turnips, cole, clover, &c. in the fields, there is no loss; the whole is immediately applied, without the cost of carriage, to the enriching of the soil." In this way there must, however, be much more waste than is here supposed: by evaporation, from the action of the sun and wind over so extensive a surface, much of the valuable matters of the manure, in such situations, must be daily carried away; and the more fibrous or ligneous parts of the materials, which are rejected as food by the cattle, from their being thinly scattered over a large surface, become dry and hard, and must be longer before they decay, or are rendered fit for the purposes of manure, than where they are collected together in large quantities, and in more confined situations.

Another mean of increasing manures to a very great extent, is by adopting such methods as may effectually prevent the soil and urine of privies, and the various animal and vegetable materials that are continually thrown into them, in cities and large towns, from being uselessly retained in deep pits, or places constructed for the purpose, or inconsiderately washed away and wasted, by being conveyed into rivers or ponds by sewers and drains. Mr. Middleton has stated, that, from want of suitable modes of preserving such substances, the annual loss, in this country, is probably not less than five millions of cart-loads, which, if turned to the uses of agriculture, would be worth to the cultivators of the soil two millions and a half, and to the community five millions of pounds sterling! And the eagerness which is manifested in many other countries to preserve and promote the increase of such manure, shews that it is a substance of vast utility, and that an abundant source of fertility is thus neglected, and lost to the public. It is supposed, by a late practical writer, that "the most easy and convenient methods of preserving substances of this kind, in the country, would be, probably, by having pits formed for the reception of them, as near as possible to the dung-steads in farm-yards or other places, and prepared with floors of clay, or some other material, through which the liquid matters could not readily pass: these might be connected with the privies by proper drains, and have covers fitted to them, in order that a quantity of mould, peat-earth, saw-dust, lime, stems of coarse garden plants, or other substances of the same sort, might be occasionally placed in them, and removed to be blended with the common dung heaps, as often as they become fully reduced by putrefaction, and well saturated and impregnated. But in large towns or cities, where such manures are produced in great quantities, reservoirs or basons of large sizes should be constructed with floors of the above kind, and be connected with the privies of different parts, by means of sewers or drains. Such reservoirs ought to be so situated as to be capable of being emptied with ease and facility, as often as necessary, by persons appointed for the purpose, and their contents carried away in the night-time. Where there is the convenience of rivers, however, as in London, and many other populous cities and towns, a large proportion of such manures might, in most cases, be readily emptied from basons of this sort, formed on their banks for the purpose.

MANURE.

poie, or perhaps from the extremities of the common sewers themselves, by means of proper sluices, into covered boats or barges, and thus cheaply carried to a distance, for the advantage of agriculture; a method, in some respects, practised with success in Sweden. See Communications to the Board of Agriculture, vol. i.

But "as this kind of manure is extremely liable, from the agitation of the carriage in which it is moved, to become fo liquid as to be conveyed with great difficulty, it is probable that, by having such earthy or other substances as have been mentioned above, or as could be conveniently procured in such large cities or towns, such as the long littery dung from livery stables, lime rubbish from the pulling down of old houses, and the fresh earth dug up in preparing the foundations for new ones, mixed and blended with it in the pits or reservoirs, for some time before they are cleaned out, the difficulties attending the carriage of it might not only in a great measure be obviated, but the disagreeable smell issuing from it be much corrected, and the quantity of manure greatly augmented. By some method of this nature, under the management and direction of proper persons, vast stores of fertility might, it is conceived, be provided in such places for the neighbouring districts, which inattention or popular prejudice at present withhold from the use of agriculture." See NIGHT-SOIL.

Besides, in particular situations, as near the sea, where shell and other small fishes can frequently be procured in large quantities, by having them well mixed and incorporated with good surface mould, turf, or peat-earth, or other matters of that sort, a vast increase of good manure may also be provided. The weeds cut from the sides of the rocks, and which are thrown up by the tides, when collected into heaps, and mixed with small proportions of lime and suitable quantities of mould or earth, may likewise contribute greatly to the increase of the compost heaps in such districts and situations.

Another material, capable of augmenting the manure heap very much, is the rich vegetable mould, and other matter, contained in the bottoms of ditches, and in boggy, hollow places, where water frequently stagnates, and large crops of aquatic or other plants alternately vegetate and decay. This should be occasionally dug up and applied to the soil, for which it is proper, either in the state in which it is found, or after having been formed into compost heaps with dung, lime, or other substance of a similar nature.

And clay, though not actually a manure, is a substance that may also be employed with great advantage on sandy and other light soils, and by that means save the more valuable manures. It has been made use of with great effect in its crude state, in the practice of an improving Suffolk farmer, but it would seem to be the most serviceable for this use after being imperfectly burnt in clamps and kilns, probably from the production of oxygen or pure air that is thus combined with it, or with the metallic matters which it contains. It is well remarked, by a late writer, that "it is necessary, in order to increase the stock of manures on farms to the greatest possible extent, to be careful that none of such animal or vegetable substances as are capable of being converted into manure, be thrown away or consumed by fire, but that they be all conveyed to the dung-heads in the farm-yards or other places, or laid in heaps of themselves, and suffered to pass into fermentation, by which they may be speedily reduced to manure. Where the matter thus made use of chiefly consists of weeds and the stems or roots of coarse plants, such as peas, beans, cabbages, docks, nettles, &c. their decay may be greatly promoted by a little quick-lime being blended with them. Such heaps should

also be covered over pretty well with some of those earthy matters that have been mentioned above." It is added, that as "the different materials which are made use of for the purpose of manure, pass through different stages of decomposition and decay, in each of which such matters of the solid or fluid kinds are formed, as are capable of contributing to the nutrition and support of vegetable crops, but which are liable to be dissipated or carried away by the agency of various causes, it may be necessary to guard against such waste by keeping the dung-heaps covered in every situation, as much as possible, with earth or soil, both in the early periods in which heat is evolved, and at the latter ones, when ammonia or volatile alkali is formed; as by such management the process of decomposition, when too rapid, may be restrained, and the elastic matters that are gradually set at liberty be absorbed by these coverings, while the more fluid ones are detained by the earthy bottoms on which they had been placed, and thus the whole of the valuable properties of the manure be preserved."

MANURE, in *Gardening*, a term used to signify all such substances or materials, whether of the dung, compost, or other kinds, as are useful in the improvement of garden ground, so as to produce good vegetable crops of various kinds.

It is obvious that materials of this kind are necessary to all soils to recruit them when exhausted by the growth of vegetables, and cure their defects; being thus beneficial in enriching and fertilizing such as are poor, and in rendering such as are strong or stubborn more light, loose, and friable, as well as those which are very light, loose, and dry, more compact and moist, and those that are too wet, drier, &c. In these views moist stiff land is the most improved by light manures, which open and loosen its particles; very light land by the more heavy and moist sorts; and wet land by dry light composts. Some garden soils also require manure annually, and others only once in two or three years. See DUNG, &c.

On the whole, the most proper sorts of manure for the use of the kitchen-garden are those of the stable, cow, sheep, pigeon dung, foot, lime, loamy marle, shell marle, sea-weed, wood, whin, fern, and coal-ashes; the vegetable mould of decayed tree-leaves, and decayed vegetables of all kinds, as cabbage leaves, haulm, weeds, &c. And to these may be added the fluid substance which drains from dung-hills, which is capable of affording the nutrition of plants in a very high degree, from the large proportion of carbonaceous matter with which it is loaded.

All these several materials may be applied either in a simple or compound state; but the latter method is probably in general the most eligible; as it is supposed by some, that if they have not undergone a proper degree of fermentation, they have the effect of giving a rank and disagreeable flavour to some fruits and vegetables; and when a large quantity is applied, of producing a considerable degree of unwholesomeness, tainting the juices of the plants. This effect is, however, much to be disputed, since the different substances are changed and elaborated in the vessels of the vegetables before they become fit for the purpose of their increase.

It is asserted by the author of the *Scotch Forcing Gardener*, that "a combination of stable dung, sea-weed, lime, and vegetable mould, which has lain in a heap for three or four months, and has been two or three times turned during that period, will make an excellent manure for most kinds of garden land." Also that of "cow dung and sheep dung, mixed with foot or any of the kinds of ashes;" and that "pigeon dung, marle, and vegetable mould, well mixed, will make

MANURE.

make an excellent manure for heavy land ; or even for lighter soils, provided the pigeon dung be used sparingly." But that "pigeon dung, lime, foot, ashes, &c. should never be applied in a simple state ; the quantity of them required being comparatively small, and the regular distribution difficult without the admixture of other matters. It is further observed, that he has "witnessed the astonishing effects of whin ashes alone, in producing herbage in a five or six-fold degree ; which was the more obvious, on account that the field on which they were applied was much alike in quality (a stiff, wet, clayey loam), and the ashes applied partially. The effect was visible for several successive years. Also, on the timber trees with which the field was afterwards planted." He conceives that "marle is an excellent manure for almost any soil ; and may be applied as a simple manure with as much propriety as any of the kinds of cattle dung, or even vegetable earth. The kind called shell marle is, it is supposed, much to be preferred ; and should be freely applied to strong lands, but sparingly to light ; the loamy kind being best adapted to light lands."

Where stable dung is used in a simple state, it "should not," it is supposed, "be applied in too rank a state, nor should it be too much fermented. It should generally lie in a heap for two or three months ; during which time it should be turned twice or thrice. A ton of it in this state is worth three that has been used in the hot-bed, and are a year old. This manure, and indeed dung of any kind, when thus applied, should never be carried from the heap to the ground till it is to be digged in ; as, by its exposure to the air, the virtues evaporate, and it is the less effectual."

And when made use of in a simple condition, it is imagined "the necessity of the instant application of sea-weed after its landing, is even greater than in the above case ; as it instantly corrupts, and its juices not only evaporate, but flow downwards, and are lost. If this manure be used as a compound, the heap wherein it is compounded should be more frequently turned on its account, that none of the juices may be lost, but that the other part of the compost may absorb them."

It is his opinion that "vegetable mould may either be used in a simple or compound state, and may be applied with equal propriety to all soils. None can be hurt by it in any degree ; since almost every plant will grow luxuriantly in it entirely, without the aid of any soil or manure whatever. It is conceived that manures have the effect of correcting tenacity, crudity, and porosity in soils, exciting their fermentation, communicating nutritive matter to them, and affording nourishment to the roots of plants, by which the vegetation and perfect growth of them are promoted and increased.

There are likewise considerable differences in the materials made use of as manures, in their affording their nutritious properties, some affording them much more readily and more abundantly than others. This is the case with animal, vegetable, and all such matters as are rich in mucilage, the saccharine principle, and calcareous earth, and which readily afford carbon, phosphorus, and some gaseous fluids, such as the carbonic acid gas, oxygen, &c. while others which are greatly deficient in all or most of these principles, or which do not part with them easily, are found by experience much less beneficial in promoting the growth of vegetables, fruits, &c.

However the effects and importance of manure are now generally acknowledged and understood, it would appear to be the indispensable duty of the gardener and cultivator to be particularly careful in the collection of it, and also to distribute it with the most scrupulous frugality. "For this pur-

pose, it is suggested that where it is capable of being formed, a well, cistern, &c. should be contrived so as to collect the dung-hill drainings ; and that in the application of manure of any kind, the greatest care should be taken to divide it equally, according to the quantity to be applied." Also, further, that "the dung-hill may be considerably increased by throwing the haulm, stalks, and leaves of all vegetables into a common heap, letting them remain till well rotted, and afterwards, or, in the process of collection, mixing them with lime, marle, ashes, foot, &c. Watering the whole frequently with the drainings of the dung-hill would also greatly enhance its value."

It is likewise evident that the ground of gardens may often be greatly ameliorated and improved by proper draining, before the manures are applied, and sometimes by the use of sandy, gravelly, and other similar materials, that have the power of opening, and rendering it less close and adhesive. See MANURE, *supra*.

MANURING of Land, in Agriculture, the application of the various substances which are capable of being employed as manures to the soil, in such a way as to produce the most beneficial effects in the production of crops, whether of the grain, grass, root, or other kinds. In this business various circumstances are necessary to be considered, such as the state or condition of the manures which are to be made use of, the nature of the ground on which they are to be laid, the kind of crop that is to be promoted by them, and the season of the year in which they are to be put into or upon the land ; for as it has been shewn that changes are continually taking place from the moment the materials of the dung-heap are thrown together, to the period in which they are reduced into a black carbonic earthy matter ; and that in most of the different stages through which they pass in this process of decomposition, such substances are formed as are capable of contributing to the nutrition and support of vegetable crops ; it is conceived "probable, that in cases where manures are to be turned into the ground, and such crops cultivated as require a supply of nourishment for a length of time, they should be employed in their long or more imperfectly reduced states, as by the heat which is evolved in the commencement of their dissolution, the process of early vegetation may be greatly promoted, and their gradual decomposition and decay afterwards, under the ground, afford a more durable and regular supply of nutrient materials, and thereby contribute more effectually to the growth of the crops ; but that where they are to be buried in, or applied to the surface of the soil, and intended merely for the benefit and support of such crops as are of short duration, or quickly arrive at their full growth, they may be more advantageously made use of after they have been more fully and completely reduced, as in this state the manure is, in the case of grass lands, not only capable of being spread out in a more regular and uniform manner, by which it becomes more evenly as well as more generally carried down to the roots of the plants by rains, but it is in the most suitable condition for allowing the young plants the means of springing up with facility, and at the same time, whether used under or upon the soil, of affording the crops that abundant supply of nourishment which is necessary to their speedy growth and great luxuriance, and by these means to contribute most perfectly to the promotion of their increase." In addition to "these advantages of long, or imperfectly decayed manures ; they have others that depend on the soil into which they are turned, and the nature of the crops that are sown or planted with them. Where they are employed in such stiff, clayey, or loamy grounds, as have a great tendency to become dry

MANURING OF LAND.

and hard, and thereby incapable of admitting the tender fibrous roots of grains or other plants to spread or extend themselves, and draw in more abundant supplies of nourishment, they may be useful by keeping the earth around them in a more open and porous state, from the slowness of their decomposition, and the gradual and continued manner in which the different elastic matters are set loose and united with the soil. Hence, when barley, or such kinds of grain as require a rather light and open state of soil, and those bulbous or knobby-rooted plants, such as potatoes, that require much room to shoot and extend themselves, are cultivated on such stiff soils, they are generally found to be the more productive, where such long or imperfectly reduced manures have been made use of in the preparation of the land." And that "as in the slow and gradual decomposition of the materials which are made use of for manures, when slightly deposited beneath the soil, there is much less waste of heat and those elastic matters which contribute so greatly to the support of vegetation, than where they are made to undergo the various processes of dissolution in large masses, as in dung-heaps, they may probably sometimes on that account be most advantageously employed in this state." Also "on this principle the ploughing down of fresh vegetable crops, in many cases, in their most succulent states, may be a more economical as well as more beneficial practice; especially in such light and dry kinds of soil, as will more readily admit of their gradual putrefaction and decay, than to cut and take them off for the purpose of being by other means converted into manure. It seems likewise probable, on the same grounds, that for the production of crops of the bulbous-rooted vegetables on the more stiff and tenacious soils, the matters made use of as manures may be employed with the greatest advantage, when put into the earth before they have undergone any great degree of decay by means of putrefaction, as in this way there is no waste, the whole being ultimately converted and applied, though more slowly, to the support of the crops for which they are immediately employed." It has been stated as the opinion of a practical farmer, that stable dung never answers better than when carried on to the land as soon as made. He laid it on a piece of wheat in frosty weather, and at harvest the crop was laid to the ground. And on grass lands, it is supposed, when laid on in the spring, to screen it from the cold winds, and occasion it to be more forward, and that in the summer the straw part protects the land from the sun; and in either season it is soon grown in and nearly lost to the eye. See Communications to the Board of Agriculture, vol. iv.

Manures, proper Season of Application.—In regard to the time or season of applying manures "with the greatest benefit and advantage, though in practice it must, in some measure, depend on the state of the land, the nature of the crop, and the convenience of the farmer, it should, in cases where they are buried in the ground, be as nearly as possible to the periods in which the seeds, or the roots which they are designed to support, are sown or placed in the earth; where they are to be laid upon the surface of the land, it ought probably to be just before the crops of grass, or other vegetables, begin naturally to spring or shoot forth." As in this practice of depositing and blending the manure with the soil, nearly at the time the crops are put in, there is scarcely any waste of the fertilizing properties of such substances, which, as they gradually proceed in their decomposition and decay under the ground, must otherwise be the case, the roots of the plants not being in the most proper states for taking them up and converting them to their support. Besides, in stiff, loamy, or clayey soils, they have a tendency,

as has been remarked above, to produce a degree of lightness and friability that is suited to the early process of vegetation." The author of *Phytologia* has well remarked, that "the atmospheric air, which is buried along with the manure in the interstices of the earth, and which for many weeks, or even months, renders the soil loose and easily impressed by the foot on walking on it, gradually evolves, by its union with carbon, a genial heat, very friendly to vegetation in this climate, as well as the immediate production of much fluid carbonic acid, and probably of a fluid mixture of nitrogen with hydrogen, which are believed to supply much nutriment to plants."

The using of such manures as are made use of in the way of *top-dressings* in the early spring, is a practice by which "they are laid on at the most favourable period for affording their nutritious principles, and for their being drank up by the roots of plants, and consequently become useful at the time they are most wanted for the promotion of the crops, and the great waste which must otherwise be caused, either by the excessive falls of rains and floods in the winter season, washing down much of the valuable properties into the adjoining rivers and ditches, or the evaporation of their more volatile or elastic matters by means of the summer heats, is most effectually guarded against and prevented." It is hinted that the practice common in some places of applying manure to grass lands in the latter end of the summer or beginning of autumn, after the first crop of hay has been taken from the ground, and the after-grass has begun to make shoots, is not by any means so favourable as that of early spring, as in the latter case the generation of those materials that contribute to the support of vegetation is greatly promoted by the constantly increasing heat of the vernal and summer months; while in the former it is constantly checked and retarded by the increasing coldness of the autumn and winter seasons. Besides, the manure, by being spread out upon the surface of the land under such circumstances, must be the cause of great loss, by contaminating the after-grass, and rendering it incapable of being eaten off by cattle or other kinds of live stock." Yet, "where a second crop of hay is to be taken, it may sometimes be put on at such times with advantage to it, especially if the weather be not too hot, and the manure in a perfectly fine and reduced state, so as not to impede the mowing. It has been remarked by doctor Fenwick, in his ingenious reflections on manures, "that it is scarcely possible to suggest a worse mode of using manures on grass lands, than that which is almost universally practised in the neighbourhood in which he resides;" and it is the same in many other parts of the country, as is evident from the reports that have been lately published by the Board of Agriculture: "When," says he, "a severe frost has bound up the land in a state of impenetrable cohesion, the farmers wheel on their dung, perhaps even when snow has covered it. While the frost lasts, the land can derive no advantage from the manure, and when a thaw supervenes, it is evident that the wash from the melting snow, or from the rains which generally fall in such weather, must deprive the mass of every part that is soluble. The ground, in the mean time, retains the frost for many days, and is therefore incapable of absorbing the wet which falls upon its surface; and even when the influence of the milder air has reached it, it can imbibe but little, being in general previously filled with water, and the quantity which flows over it being too great for soil, under any circumstances, to drink up." It is believed by the same writer, that in support of this destructive and wasteful practice, however much it may have been defended on the ground of the farmer's leisure or convenience, and the little injury

MANURING OF LAND.

injury done to the turf or sward of the land, there can be only one reason alleged, which is, that manure, when spread early in the winter, may protect the roots of grasses from the severity of frosts. And this, the author of "Practical Agriculture" says, "is probably a mistaken notion, as it is known to every one that the common grasses are seldom injured by the severest frosts; and other kinds of grasses may probably not suffer less injury from the application of manure at such a season, than from the severity of frosts." It is therefore concluded, that "on all these accounts, farmers should contrive as much as possible to apply the manures, intended as top-dressings to grass lands, as early in the spring as it can conveniently be done, which may be easily managed on those that are dry, and on such as are inclined to be wet and poachy, it may probably be greatly facilitated by having small light carts constructed for the purpose, and placed on broad cylinders as wheels." For he is convinced, from the trials which he has made in applying manures to grass lands at such periods, that the trouble of the farmer will not only be rewarded by much larger crops of hay, but also by a considerable increase in the quantity of the after-grass; and, besides, his crops in both instances will be more forward than in the ordinary methods of putting them on, either in the autumn or winter months, which in many cases is a circumstance of great importance." There are others, however, who consider the early autumn as by much the best season, as may be seen under the head of manuring new laid down grass lands at first. See *LAYING down to grass*.

In Young's calendar of husbandry, it is stated, that "the proper season for laying on several sorts of manure, such as foot, coal-ashes, wood-ashes, lime, malt-dust, &c. and in general all those that are spread in too small quantities to require a whole winter's rains to wash them in," is in February. The use of these manures, and other light dressings at this period, is, he says, very beneficial; "but, throughout the management of purchased manures, experiments should be formed for a year or two, before the practice is extended, to see which, at a given price, will suit the land best. Without this precaution, a farmer may probably expend large sums of money to little purpose. Nor would he advise him to trust to the mere appearance of the effect soon after the manuring; for some of them, particularly foot and malt-dust, will shew themselves after the first heavy showers, in a finer green than the rest of the field; but the proof of the effect does not arise from fine greens, but from weight of hay; for he has himself found from experience, that the latter is not always an attendant on the former. Contiguous half-acres, or roods, should be marked out, the prices of the manures calculated, and on each piece a separate one spread, all to the amount of 20s. an acre, for instance, at hay-time, the crops should be weighed. It will then be known which manure, at the given prices, suits the soil best. This knowledge will prove true experience, and a very different guide from general ideas." And "this is likewise, he adds, the season for spreading superficial dressings on the green wheats, such as foot, ashes, malt-dust, pigeons'-dung, poultry-dung, rabbits'-dung, &c. and many other sorts in the neighbourhood of great cities. It is very good husbandry; but the profit depends on the expenses." He therefore recommends "trying them in small portions, (a rod, for instance, to each) before extending the practice to whole fields, especially those which are not dungs. As to the latter, provided the prices be not extravagant, there can be no doubt of their answering to all soils. Whenever a farmer has the choice of manures, never let him hesitate about which to take. He may lay it down as a

maxim, that dungs of all sorts are excellent. Other manures may be the same, but they are not, he thinks, so universally beneficial to all soils."

It is also stated, that furriers' clippings are sown by hand from the feed scuttle, at about 3d. per quarter, in March, on the land intended to be sown with wheat or barley, and immediately ploughed in, after which the seed is sown and harrowed in, when such pieces of the clippings as are left above ground by the harrow, are pricked or shovelled into the ground by the end of a flick, to prevent their being devoured by dogs or crows, who seize them greedily. From two to three quarters are usually sown per statute acre. These clippings are said to answer well on light dry chalk or gravelly soils, where they are supposed to hold moisture, and help the crop greatly in dry seasons, but they have little effect on wet soils. And horn shavings, which are of two sorts, small and large, are used in the same way and quantities as the above article, except that they want no pricking; and the large are generally ploughed into the land three months before sowing wheat or barley. This sort of shavings answers well in moist soils and seasons, except very dry ones, when they will not work. The small shavings are much the most useful. Woollen rags are also sown by hand and ploughed in three months before sowing wheat or barley; the quantity used is from six to ten cwt. per statute acre. Woollen rags, like furriers' clippings, hold moisture, and are adapted for dry, gravelly, and chalky soils, and succeed in dry seasons better than most manures, but they do little good on wet soils. London rags are found much better than those collected in the country; but the danger of catching the small-pox in chopping and sowing them, deter many farmers from making use of them. Sheeps'-trotters, and fellmongers' cuttings, are used in the same way as furriers' clippings, from 20 to 40 bushels per acre, and need pricking in, as dogs and crows are very fond of them. They do not answer on wet land, or in very dry seasons; indeed nothing does succeed in excessive dry seasons on these soils. Malt-dust is also sown by hand from 24 to 32 bushels per acre, at the same time as barley, and harrowed in with the seed. It suits moist soils and seasons; but it quickly spends itself, and is therefore never sown with wheat; as a top dressing to wheat in March, at about 30 bushels per acre, it would probably succeed on these sorts of soils. Pigeons'-dung is used in the same manner as malt-dust, and does good in any soil or season. Soap boilers' ashes have also a great effect on cold sward. Hogs' hair, when applied in the same manner as clippings, is said to answer well. And seal hair, rabbits' dung, and lime, have been tried upon these kinds of soils, but not found to answer in any very advantageous degree.

Depths of depositing Manures in Soils.—It is stated by a late writer, that as "the putrefaction and decay of animal and vegetable matters, whether above or beneath the ground, is greatly promoted by the free admission of air, and a suitable degree of moisture, it is evident that they should not be buried so deep in the earth, as that they may be prevented from readily receiving the aid of such causes in forwarding their decomposition; nor, as the process is known to be much retarded by the substances being rendered too dry, should they be placed so near the surface, or be so thinly covered as to permit the action of the sun and winds, before the crops have risen to such heights as to prevent it from dissipating and carrying away their nutritious properties. The introduction of the manure to a middling depth, as three or four inches, would of course, on these accounts, as well as from its contributing more expeditiously and more fully to the vegetation of the crops
that

MANURING OF LAND.

that may be put in with it, seem, in general, to be the most advantageous practice; but on the lighter and more friable soils, it may be advisable to plough it into a greater depth than in such as are heavy and tenacious. In every case, however, whether the manure made use of be in a long or a more reduced state, it should be perfectly covered or ploughed into the earth. The practice of burying manures deep in the soil, has been defended by some on the ground of its being the nature of elastic matters to rise or force themselves towards the surface; but when they are placed to a considerable depth in the earth, as the process of decomposition is thereby stopped, or suffered to proceed in but a very slow and feeble manner, little or nothing escapes for the support of vegetation, or it is furnished in so very slow and sparing a way, as to be of scarcely any service to the immediate crops. Thus, in the cultivation of such crops as are placed in rows or drills, where the manure is put into a great depth and covered pretty thickly with earth, on digging them up at the end of many months, it may frequently be observed nearly in the same state it was when first put into the ground. And the same thing is often noticed by gardeners, where imperfectly reduced, or long dung is placed in deep trenches and covered to a considerable thickness with mould." It is also added, that "in order that manures may produce their effects in the most perfect manner, they should be spread over the surfaces of the grounds as evenly as possible, whether they be intended to be turned into the soil or left upon its surface as top-dressings;" a point that "may be greatly facilitated by placing the manure out at first in very small heaps, as by such a practice it may be spread over the ground with much greater ease and exactness; and on grass lands much less injury will be done by the bottoms of the heaps."

And it is evident, that on tillage lands, manures should always be turned in, or otherwise covered, as soon as possible after they are spread out; for if this be neglected, much loss may be sustained, especially in hot seasons, by the quick evaporation that takes place in such cases. The best practice is, of course, not to carry more out from the dung-hill at a time, than can be conveniently spread upon and ploughed into the earth in a short time afterwards. It is observed in a periodical work, that the shortest possible space of time should be suffered to elapse between the spreading out the manure, and the ploughing it into the lands, as well as between this last operation and that of sowing the seed. And it has been suggested, that "in spreading manures employed as top dressings on grass lands, much advantage will be gained by breaking and reducing the clods or lumps into as fine a state as possible, as by such means they are not only applied more perfectly, but washed by the rains much more readily to the roots of the grasses. The springing of the young grasses is also less retarded, where the manures are rendered fine and powdery, than where they are left in a cloddy, rough state." The nature of the soil, and the purpose for which the manure is applied, should likewise be carefully attended to in this business, as no one method is adapted to every case that may happen.

It is stated, in respect to the economy of their application, that "it seems not improbable but that some degree of saving may occasionally be made, by applying them on lands under tillage, as well as others, nearly at the time the seeds and roots are put into the ground, or when the grasses begin to shoot; as from the whole of the manure being in this way made to contribute directly to the support of the crops, a less quantity may be sufficient for the purpose: how far they may be safely diminished on this principle, can only be shewn by actual experiments and accurate deductions

made from them; but there are sufficient grounds, from what has been observed, for supposing that it may be considerably more than can be easily apprehended by those who have not adverted much to this circumstance. There is another economical mode of employing manure, which is, by placing it in the drills or hollows formed for the reception of different crops which are cultivated in rows, as peas, beans, cabbages, potatoes, &c.: by this method, that part of the ground which is intended to bear the crop, is only manured, the intervals or spaces between the rows not receiving any, from which, where the business of putting the manure into the drills is properly performed, a great saving must of course be made."

According to the conclusions of some, "the saving of manure in this way is so great, as to constitute one of the chief advantages of the drill system of cultivation. And the calculation of the experienced farmer is, that by "drills being made two feet asunder, and each drill six inches wide at the bottom, there will be just one-fourth part of the ground covered with manure; for as six inches multiplied by four gives two feet, which will be the distance from drill to drill, and as four multiplied by four makes sixteen, it follows, that if the whole of the land had been covered with manure, sixteen loads would have been required for what is as fully and beneficially performed by four, that is, by one quarter of the quantity used by the old method of dressing, supposing it of the same thickness and quality." Besides, from the manure being in this way kept more closely together, and the crops placed immediately upon it, they must, he suspects, receive the advantage of the dressing in a more full and complete manner than under other circumstances could be the case.

Dr. Dickson, in his work on practical agriculture, suggests, that "as it appears probable that in the decay of different materials in the soil, all the nutritious matters as they are formed immediately become useful for the purpose of vegetation, without any waste being sustained, as must always be more or less the case where they are deposited together in heaps, it may be an economical practice, in cases where the crops to be benefited by them require a regular and lasting but not large supply of nourishment; or where the ground is required to be kept in an open and rather light state, for a considerable length of time, to employ such manures in their less decomposed states, as by the ploughing down of green succulent vegetable crops, and the turning in of long strawy substances. By adopting such means, the more perfectly formed manures of the farm may be reserved for such crops of luxuriant vegetables as demand more speedy and abundant supplies of nutrient matters." And in what respects the advantage of using one sort of manure in preference to another, it may be remarked, "that as animal matters are found in general to undergo more speedily the process of putrefaction or decomposition than those of the vegetable kind, and as in most instances they afford those mucilaginous and elastic principles that contribute so largely to the support of vegetable life in greater proportions; such manures as are either wholly or in a great measure composed of them, must be the most beneficially employed, where quick and abundant supplies of nourishment are required, as in the growth of all the more gross and luxuriant crops, whether of grain, plants, or grasses; and that as those vegetable substances which contain saccharine, farinaceous, oily, saline, or mucilaginous principles in the largest quantities are ascertained from experience to proceed the most readily into the state of dissolution or decay, and consequently to afford more fully and more expeditiously the nutrient food of new plants, where

manures

manures are principally formed from them, they should be preferred to such as have been made from the harder and more ligneous vegetable substances, that contain such properties in scarcely any, or much smaller degrees, for all the purposes of agriculture." Lastly, that "such substances as are found to contain those elementary materials of which vegetables are principally constituted in their more soluble or loosely combined states, as carbonaceous matter in the black earths or moulds, and oxygen, azote, and hydrogen, in burnt clay, ruddle, manganese, and calamy, substances which have hitherto been little employed, as well as in water and air, should be made use of in preference to those which possess them in slight proportions or scarcely at all."

With regard to the particular modes of preparing and making use of the several articles that are capable of being applied to lands so as to ameliorate and improve them in the production of different sorts of crops, they will be more fully explained under the particular heads to which they immediately relate.

MANUS was anciently used for an oath, and for him that took it as a compurgator. And it often occurs in old records: *tertia quarta, &c. manu jurare*; that is, the party was to bring so many to swear with him that they believed what he vouched was true: and we read of a woman accused of adultery: *mulieri hoc neganti purgatio sexta manu exitit indicia*: i. e. She was to vindicate her reputation upon the testimony of six compurgators. Reg. Eccl. Christ. Cant. If a person swore alone, it was *propria manu & unica*. The use of this word came probably from its being required at a person's hands to justify himself; or from laying the hand upon the New Testament, on taking the oath.

MANUS *interosseti*. in *Anatomy*. See INTEROSSEI.

MANUSCRIPT, a book, or paper, written with the hand. By which it stands opposed to a printed book, or paper. A manuscript is usually denoted by the two letters MS. and, in the plural, by MSS. or MMSS. What makes public libraries valuable, is the number of ancient manuscripts deposited in them. See ALEXANDRIAN, CAMBRIDGE, CLERMONT, COTTONIAN, HARLEIAN, VATICAN, &c.

MANUZIO, ALDO, the elder, in *Biography*, a celebrated printer and man of letters, was born at Bassano, in 1447. Having laid a good foundation, at his native place, in grammar learning, he was sent to Rome, where he pursued his classical studies under Gaspar da Verona, and removing thence to Ferrara, he had the advantage of learning Greek from Battista Guarino. During his residence at the latter city he was employed to give private lessons to Alberto Pio, prince of Carpi, and to Hercules Strozzi, afterwards a distinguished poet. In the war between the Venetians and the duke of Ferrara, in 1482, Aldo was obliged to quit that city, and he took up his abode with that patron of literature John Pico of Mirandola. He afterwards visited his pupil Pio, and it is probable, that with the assistance of these two enlightened nobles, he set up a printing office at Venice, for the purpose of giving correct and elegant editions of the Greek and Latin classics. His first work did not appear till 1494, after the press had been established about six years; but in the course of the next twenty years he had printed almost every Greek and Latin classic, as well as a number of other books. He was the inventor of the Italic character, called for a considerable time the *Aldine*, and obtained from the senate of Venice, and the pope, patents for its exclusive use for a number of years. To render the editions that issued from his press correct, he procured the assistance of some of the best scholars of the age as editors. Aldo likewise established a kind of academy in

his own house, at which the literati of Venice assembled, on fixed days, to discuss various literary topics. Aldo was very desirous of rendering his academy perpetual, but it did not long survive him, though it was succeeded, not long after his death, by the Venetian academy. He married the daughter of Andrea d'Asola, from whom he obtained some pecuniary assistance, and with whom he entered into partnership. The wars of Italy impeded their labours, and by these Aldo lost a very considerable property, which he took much pains to recover, and in the attempt fell into the hands of the soldiers of the marquis of Mantua, by whom he was plundered and imprisoned; but on making himself known, he was liberated with much respect. This was in the year 1506, and during the six subsequent years, he printed very little, but in 1513 and 1514 he resumed his labours; and was closely engaged in his employment, when he was carried off by disease in April 1515. Aldo Manuzio held a school in Venice for the Greek language: that his own learning was considerable, there are abundant proofs in the dissertations and prefaces of his own compositions, which are prefixed to his editions of the Greek and Roman authors; and also in his Latin letters that have been printed in various epistolary collections. He published a Latin grammar compiled by himself; and a treatise "De Metris Horatianis:" he translated various pieces from the Greek into Latin, and he compiled with great labour a Greek dictionary. He was visited by all the learned strangers who came to Venice; but to prevent a waste of time which he could ill afford, he put up an inscription over his study door, desiring that visitors would make their stay very short, unless they had something important to communicate. Though his editions were not, and could not be expected to be, immaculate, yet there are but few persons to whom literature is more indebted than to Aldo Manuzio.

MANUZIO, PAULO, son of the preceding; an eminent scholar and printer, was born at Venice in 1512. He received the rudiments of an excellent education at Asola, whence he was early removed to a more learned instructor at Venice, under whom he made extraordinary progress. When he had attained to his twenty-first year, in 1533, Paulo re-opened the printing office which had been shut from the death of Andrea, and the business was conducted under the joint names of the heirs of Aldo and Andrea. In 1535 he paid a visit to Rome, on the promise of an establishment there; but his hopes were for the present entirely disappointed, and the only advantage which he derived from his journey was the friendship of some learned men in that capital. After his return, he opened an academy for the instruction of twelve young men of family, in polite literature: he continued in this employment about three years, and then made a tour through the cities of Italy, for the purpose of examining the best libraries. His reputation for learning procured him several offers of professorships, but he did not engage in any of them, and his appointment to superintend a printing office set up by the academy of Venice gave occasion to his becoming distinguished in his proper profession, by several very elegant and accurate works; the institution was, however, but of a short continuance. About this time his eyes were so weak, or diseased, that he was obliged to quit his studies till he obtained complete relief by the assistance and advice of Fallopius. A liberal and magnificent plan had been formed at Rome for the printing of all the most valuable Greek MSS. in the Vatican. In the mean time, the progress of the Reformation, and the sitting of the council of Trent, had rendered theological works in great request, and it was determined to give Vatican editions of the fathers and other ecclesiastical writers, which might furnish weapons to the

defenders

defenders of the church. To unite correctness with elegance in these editions, the pope, Pius IV., invited Paulo Manuzio to Rome; he accepted the invitation, and arrived in the summer of 1561. The press provided for him was in the Capitol, the palace of the Roman people, whence the works printed at it were inscribed "Apud Paulum Manutium in *Ædibus Populi Romani*." In 1570, either dissatisfied with his emoluments, or finding the air of Rome injurious to his health, he returned to Venice. From this period he spent much of his time in travelling from place to place, till at length pope Gregory XIII. engaged him to stay at Rome by the offer of a pension, which allowed him to devote all his time to his studies. He died at Rome in April 1574, in the sixty-second year of his age. The learned world is indebted to Paulo for many valuable works of his own, besides those of others which he ushered into the world. He was the diligent annotator on the works of Cicero and Virgil; he was much attached to the study of Roman antiquities, and was the first who discovered the Roman calendar, which he published from his son's press with two tracts, "De veterum dierum ratione," and "Kalendarii Romani explicatio." He had formed the plan of a great work in which every topic of Roman antiquities was to be illustrated, but of this he only published "De curia Romana." He formed a collection of letters, as well Italian as Latin, and among these, his own letters in both languages may be compared with the best of other writers. His Latin letters have frequently been reprinted, and are truly Ciceronian in their style: the Italian compositions are valued for their unaffected elegance and simplicity. He published many other works which were esteemed and applauded by the first scholars of his age: and as a printer he has merited high praise, as well on account of the beauty as the accuracy of his editions.

MANUZIO, ALDO, the younger, son of the preceding, was born in 1547. His father paid the utmost attention to his education, and so extraordinary was the progress of the youth in learning, that he was enabled to give the world "A Collection of elegant Phrases in the Tuscan and Latin Languages," when he was only eleven years of age. Other juvenile works at different periods marked his advances in classical literature, and he soon became his father's assistant in his labours, both learned and typographical. He, when very young, conducted the printing business at Venice while his father was engaged at Rome. In 1572 he married a lady of the Giunti family, so well known in the annals of typography, and on the death of his father, in 1574, all the concerns of the Aldine press devolved upon him. He was, however, less calculated for the business of a printer, than for the profession of an author. In 1577 he was appointed professor of the belles lettres in the school of the Venetian chancery, in which young men designed for public employments were educated. This office he held till the year 1585, when he was made professor of rhetoric at Bologna. In the same year he published the "Life of Cosmo de Medici," which was so well received, that he was almost immediately invited to undertake the professorship of polite literature at Pisa, which he accepted, although he received an invitation at the same time to a professorship at Rome, which had been lately held by Muratus. During his stay at Pisa he received the degree of doctor of laws, and was admitted a member of the Florentine academy, on which occasion he delivered an eloquent oration "On the Nature of Poetry." He now paid a visit to Lucca in order to obtain materials for a "History of Castruccio Castracani," which he afterwards published, and which is much applauded by De Thou. The Roman professorship being reserved for him he re-

moved thither in 1588, and intending to spend his life there, he caused his whole library to be brought to Rome from Venice, at a very great expence. He was in high favour with Sixtus V., who gave him an apartment in the Vatican, and a table at the public expence. He was also patronized in various ways by Clement VIII. He died in the 51st year of his age in the month of October 1597. He left no posterity, and with him ended the glory of the Aldine press. His library, consisting of 80,000 volumes, collected by himself and his predecessors, was sold to pay his debts. He was author of many performances besides those already mentioned, but the most celebrated of his works were his "Commentaries on all the Works of Cicero," in ten volumes. His "Familiar Letters," published in 1592, were highly esteemed.

MANWAS, in *Geography*, a town of Hindoostan, in Boggilund; 30 miles S.E. of Makoonda.

MANWORTH, in *Old Law Books*, denotes the price, or value, of a man's head.

In ancient times, every man, according to his degree, was rated at a certain price, according to which, satisfaction was made to his lord, if any one killed him.

MANZANARES, in *Geography*, a river of Spain, which passes by Madrid, and runs into Herares, about eight miles below that city.—Also, a river of America, in the Caraccas, which washes the city of Cumana. Its refreshing stream fertilizes lands otherwise sterile, which are thus rendered productive of fruits and vegetables in abundance.

MANZANAREZ, a town of Spain, in the province of New Castile and district of La Mancha, the population of which is estimated at about 6768 persons. The houses are built with mud, and the poor are almost naked. It is one of the principal quarters of the royal Carabineers. The castle, with a considerable estate, and the tithes, belong to the knights of Calatrava, and yield a revenue of 3295*l.* per annum. The land about it produces corn, saffron, and good wine. The vineyards are numerous, and this part of the country produces the best wine in La Mancha, and which is most esteemed at Madrid. It has the flavour of the richest Burgundy, with the strength and body of the most generous port.

MANZANEDA, a town of Spain, in the province of Galicia; 20 miles E. of Orense.

MANZANELLO, a town of Spain, in the province of Leon; 23 miles E.S.E. of Valladolid.

MANZANILLA KEY, a small rocky island near the S. coast of Cuba. N. lat. 20° 54'. W. long. 77° 38'.

MANZAT, a town of France, in the department of the Puy de Dôme; 9 miles N.W. of Riom.

MANZEL. See CARAVANSERA.

MANZINSKOI, in *Geography*, a fortress of Russia, in the government of Irkutsk, on the borders of China; 30 miles S.S.E. of Selenginsk. N. lat. 49° 5'. E. long. 108° 44'.

MANZOLI, GIOVANNI, in *Biography*, an opera singer of the first order, born at Florence, and gifted with the finest *soprano* voice which has been heard on our lyric stage in our memory. He was, during many years, the first singer in Italy; and when the court of Spain determined on having Italian operas performed under the direction of Farinelli, Manzoli was engaged for the principal man's part. From Madrid he went to Vienna, at the celebration of the emperor Joseph's first marriage. In 1764, he arrived in England, during the opera regency of Messrs. Gordon and Vincent, at which period the serious opera acquired a degree of favour to which it had seldom mounted since its first establishment in this country.

The expectations which the high reputation of this performer had excited were so great, that, at the opening of the theatre in November, with the pasticcio of Ezio, there was such a crowd assembled at all the avenues, that it was with very great difficulty we obtained a place, after waiting two hours at the door. Manzoli's voice was the most powerful and voluminous soprano that had been heard on our stage since the time of Farinelli; and his manner of singing was grand and full of taste and dignity. In this first opera he had three songs, composed by Pescetti, entirely in different styles: *Recagli quell' acciaro*, an animated *aria parlante*; *Caro mio bene addio*, an adagio in a grand style of cantabile; and *Mi dona mi rende*, of a graceful kind, all which he executed admirably. The lovers of music in London were more unanimous in approving his voice and talents than those of any other singer of the last century.

The applause was hearty, unequivocal, and free from all suspicion of artificial zeal;—it was a universal thunder. His voice alone was commanding from native strength and sweetness; for it seems as if subsequent singers had possessed more art and feeling; and as to execution, he had none. However, he was a good actor, though unwieldy in figure, and not well made in person; neither was he young when he arrived in London; yet the sensations he excited seem to have been more irresistible and universal, than we have ever been witnesses to in any theatre. This great singer remained in England but one season, when, returning to Italy, he was succeeded by Elisi.

In 1770 we heard Manzoli sing at Florence in a convent at the last consecration of six nuns; he had quitted the stage, and his voice, though in a small chapel, seemed much less powerful than when he was in England; and it was then said by those who had heard him before, that, powerful as his voice appeared to all who heard him for the first time, it had been still better. This great vocal performer and worthy man died at Florence in 1791.

MANZORA, or CHIREIRA, in *Geography*, a river of Africa, which joins the Zambeze, S. lat. 16° 35'. E. long. 34°.

MANZORAH, a river of Hindoostan, which is a branch of the Godavery: this is a considerable river, which rises in the country of Amednagur, and after a circuitous course, joins the main river below Nander.

MANZUREKA, a river of Russia, which runs into the Lena, N. lat. 53° 45'. E. long. 106° 34'.

MANZURSKA, a town of Russia, in the government of Irkutsk; at the junction of the Manzureka and Lena; 32 miles S.E. of Vercholenisk.

MAO, or MAU, in *Botany*, a name by which some authors have called the *magna Indica*, or Indian mango-tree.

MAO, in *Geography*, a city of China, of the second class, in the province of Se-tchuen; 55 miles N. of Tching-tou. N. lat. 31° 38'. E. long. 103° 32'.

MAON, a small island in the Adriatic, near the coast of Dalmatia. N. lat. 44° 44'. E. long. 15° 1'.

MAON, in *Ancient Geography*, a strong city of Palestine, in the tribe of Judah, which gave name to the neighbouring wilderness. It stood on a barren eminence, at a little distance to the S.W. of the Dead sea.

MAOPONGO, in *Geography*, a town of Africa, in Benguela, and capital of a district. S. lat. 10° 30'.

MAOUNA, or MASEACRE *island*, one of M. Bougainville's Navigator's islands in the South Pacific ocean, visited by La Perouse in 1787. This island is surrounded by a reef of coral, on which the sea breaks with great force; but the reef almost joined the shore, and the coast formed several little coves, in front of which were inlets where ca-

noes could pass, and probably, says La Perouse, our barges and long boats. At the bottom of each of these creeks were numerous villages, whence came out a number of canoes in succession laden with pigs, cocoa nuts, and other fruits, which were exchanged for glass trinkets. When M. de Langle and several officers landed, night came on, and the Indians lighted a great fire to make the landing place clear; and hither they brought birds, pigs, and fruit. Upon the first visit, while perfect tranquillity and apparent good humour prevailed, and whilst the crews of La Perouse's frigates were filling with water, he entered a charming village situated in the midst of a wood, or rather orchard, the trees of which were weighed down by fruit. The houses were placed in the circumference of a circle, about one hundred and fifty fathoms in diameter, the centre of which formed a large open place, with a grass plot of the most beautiful verdure, and the trees which overshadowed it kept up a delicious freshness. Women, children, and old men accompanied their new visitor, and invited him into their houses, where they spread the finest and freshest mats upon the ground, formed by small picked pebbles, and which they had raised about two feet to protect them from the damp. In the handsomest of these huts, probably belonging to the chief, was a large room of lattice work, equally well executed with those about Paris. This charming country, says our navigator, united the twofold advantage of a soil fertile without culture, and a climate which required no clothing. Bread fruit, cocconut, banana, guavas, and orange trees furnished the inhabitants with abundance of wholesome nourishment; while fowls, pigs, and dogs, which live on the refuse of these fruits, afforded them an agreeable variety of food. They were so rich, and in want of so little, that they disdained our instruments of iron and stuffs, and coveted only some beads: burdened with real goods, they only wished for things that were useless. Our navigator was ready to pronounce the inhabitants of this richly stored and beautiful island the most happy beings on earth. But he soon found that this pleasant abode was not the mansion of innocence. Although no arms were perceived, yet the bodies of these Indians, covered with scars, proved that they must be at war with their neighbours, or quarrel among themselves; and their countenances indicated a ferocity imperceptible in the physiognomy of the women, whose persons were agreeable, and manners soft, lively, and engaging. Nature, says our author, had without doubt left this stamp on the figure of the Indians to denote, that man, almost wild and in a state of anarchy, is a being more mischievous than the fiercest of the animal creation. This first visit, however, did not pass off without private quarrels, which were terminated by prudent and wary conduct on the part of our navigators. The islanders became in process of time bold and insolent, and regardless of every restraint to which they were subjected. The two frigates had during their stay trafficked for 500 pigs, a great quantity of fowls, pigeons, and fruit, and all at the expence of a few beads of glass. La Perouse gave orders for quitting the island before the storm burst, which he perceived to be gathering, and the harmonious intercourse that had subsisted was interrupted, which he saw likely to be the case; but M. de Langle, the post captain, persisted in his purpose of obtaining a few long-boat loads of water before he left the island: the consequence was disastrous; the islanders became turbulent; and M. de Langle formed a body of 60 men from among the choicest men of the crews, armed them with muskets and cutlasses, and mounted six swivels in the long-boats, and thus prepared, they landed in order to ob-

tain water. The number of canoes increased, and the number of islanders, who were collected in hostile array on the shore, amounted to 10 or 1200. M. de Langle and his companions betook themselves to their boats amidst volleys of stones, and the Indians furrounded them within the distance of a toise: after a shower of stones, M. de Langle had only time to fire his musket twice, when he was knocked down, and unfortunately fell over the larboard side, 200 Indians immediately massacring him with clubs and stones. Of the 61 men who had engaged in this expedition, 49 saved themselves by swimming to the barges of the frigates, but the remaining number fell a sacrifice to the relentless fury of these savages, and all the others were grievously wounded more or less. M. de Lamanon, the philosopher and naturalist, was one of the number who lost his life on this occasion. Many of the Indians were killed or wounded in this conflict. M. de Vaujuas closes his narrative of this event with the following general remark: "All those who were on shore can bear witness, like me, that no violence, no imprudence on our side provoked the attack of the savages. Our captain had, with respect to this, issued the most strict orders, which no one disobeyed." Captain Edwards calls this island "Otutuel." The anchoring place was in S. lat. $14^{\circ} 22'$. E. long. $189^{\circ} 1'$. Peroufe's Voyage, vol. ii.

MAP, a plain figure, representing the surface of the earth; or a part of it, according to the laws of perspective.

A map is a projection of the surface of the globe, or a part of it, on a plane surface, representing the forms and dimensions of the several countries and rivers; with the situation of cities, mountains, and other places.

Maps are either *universal* or *particular*.

MAPS, *Universal*, are those which exhibit the whole surface of the earth, or the two hemispheres.

MAPS, *Particular*, are those which exhibit some particular region, or part of the earth's surface.

Those of each kind are frequently called *geographical*, or *land-maps*, in contradistinction to *hydrographical*, or *sea-maps*, representing only the seas and sea-coasts; and properly called *charts*; which see.

There are three qualifications required in a map: 1. That all places have their just situation with regard to the chief circles of the earth, as the equator, parallels, meridians, &c. because on these depend many properties of regions, as well as celestial phenomena. 2. That the magnitudes and forms of the several countries have the same proportion as on the surface of the earth. 3. That the several places have the same distance and situation with regard to each other, as on the earth itself.

For the foundation of maps, and the laws of projection, see PERSPECTIVE, and PROJECTION of the Sphere.—The application of these principles and laws, in the construction of maps, is as follows.

Construction of a Map, the Eye being placed in the Axis.—Suppose, v. g. the northern hemisphere to be represented with the eye on the point of the axis, v. g. the south pole: for the plane on which the representation is to be made, we take the plane of the equator, and, from all the points of the surface of the northern hemisphere, conceive lines passing through the plane to the eye; which points, connected together, constitute the map required.

In this case, the equator will be the limit of the projection; the pole, the centre. The meridians will be right lines passing from the pole to the equator: the parallels of latitude, &c. circles concentric with the equator; and all the other circles, and arcs of circles, as the horizon, ver-

tical circles, &c. ecliptic, &c. conceived in that hemisphere, will be ellipses, or arcs of ellipses.

The better to apprehend the projection of the circles of the plane, conceive a radiant cone, whose vertex is the eye, its base the circle to be represented, and its sides the rays passing between the circle and the eye. Suppose this cone cut by the plane, it is obvious, that, according to the various position of the cone, there will be a different section, and consequently a different line of representation.

For the Application of this Doctrine in Practice.—In a plane, v. g. a paper, take the middle point P (Plate I. Geography, fig. 4.) for the pole; and from this, as a centre, describe a circle of the intended size of your map to represent the equator. These two may be pitched on at pleasure, and from these all the other points and circles are to be determined. Divide the equator into 360° , and drawing right lines from the centre to the beginning of each degree, these will be meridians; whereof that drawn to the beginning of the first degree, we suppose the first meridian.

For the parallels.—There are four quadrants of the equator; the first, 0.90 ; the second, 90.180 ; the third, 180.270 ; the fourth, 270.0 ; which, for the better distinction, we will note with the letters AB, CD, BC, DA. Taking one of these, v. g. BA; from the several degrees of it, as also from $23^{\circ} 30'$, and $66^{\circ} 30'$ of it, draw occult right lines to the point D, marking where these lines cut the semidiameter APC; and from P, as a centre, describe arcs passing through the several points in APC.—These arcs will be parallels of latitude. The parallel at $23^{\circ} 30'$ will be the tropic of Cancer, and that at $66^{\circ} 30'$, the arctic circle. The meridians and parallels thus described, from a table of longitudes and latitudes, lay down the places; reckoning the longitude of each place on the equator, commencing at the first meridian, and proceeding to the meridian of the place; and for the latitude of the place choosing a parallel of the same latitude: the point in which this meridian and parallel intersect, represents the place: and in the same manner all the other places may be determined, till the map be complete.

For the ecliptic, half of which comes in this hemisphere, we have observed, that it makes an ellipsis; so that the points through which it passes are to be found. The first point, or that in which the ecliptic cuts the equator, is the same with that in which the first meridian cuts the equator, which is therefore distinguished by the sign of Aries: the last point of this half ellipsis, or the other intersection of the equator, and ecliptic, viz. the end of Virgo, will be in the opposite point of the equator, viz. at 180° . The middle point of the ellipsis is that in which the meridian 90 cuts the tropic of Cancer. Thus we have three points of the ecliptic determined: for the rest, viz. for 1° and 15° of Taurus, 1° and 15° of Gemini, 1° of Leo, 1° of Virgo; the declinations of those points from the equator must be taken from a table, and set off in the map. See DECLINATION, &c.

Thus, where the meridian of 13° cuts the parallel of 5° , that point will be 15 degrees of Aries. Where the meridian 26° cuts the parallel $11\frac{1}{2}$, will be the first degree of Taurus; and so of the rest. These points, being all joined by a curve line, will be a portion of an ellipsis representing the ecliptic.

Maps of this projection have the first qualification above required; but they are defective in the second: the surface being stretched farther, as it approaches nearer the equator. With respect to the third, they are still farther erroneous.

By

By this method may almost the whole earth be represented in one map, placing the eye, *v. g.* in the antarctic pole, and assuming for the plane of projection that of some circle near it, *v. g.* the antarctic circle. Nothing is here required besides the former projection, but to continue the meridian, draw parallels on the other side of the equator, and complete the ecliptic; but this distorts too much for practice.

This projection is the easiest: but that where the eye is placed in the plane of the equator, is preferred for use. It is, in effect, of the latter kind that maps are ordinarily made. The former are added to them, in small, by way of supplement, to represent the intermediate spaces left between the two hemispheres.—Farther, as the situation of the ecliptic, with regard to the earth, is continually changing; strictly speaking, it has no place on the earth's surface: but is used to be represented according to its situation, at some certain moment; *viz.* so that the beginning of Aries and Libra may be in the intersections of the first meridian and equator.

Construction of Maps, with the Eye in the Plane of the Equator.—This method of projection, though more difficult, is yet much more just, more natural, and more commodious, than the former. To conceive it, we suppose the surface of the earth cut into two hemispheres by the entire periphery of the first meridian, each of which hemispheres we represent in a distinct map. The eye is placed in the point of the equator 90° distant from the first meridian: and for the transparent plane, wherein the representation is to be, we take the plane of the first meridian. In this projection, the equator is a right line, and the meridian, 90° distant from the first, is also a right line; but the other meridians, and all the parallels of the equator, are arcs of circles, and the ecliptic is an ellipsis.

The method is thus: From a point E as a centre (*fig. 5.*) describe a circle according to the intended size of the map. This represents the first meridian, and its opposite; for drawing the diameter BD, there arise two semicircles, the one of which, B A D, is the first meridian, the other, B C D, its opposite, or the meridian of 180° . This diameter, B D, represents the meridian of 90° degrees, of which the point B is the arctic pole, and the point D the antarctic. The diameter A C, perpendicular to that B D, is the equator. Divide the quadrants A B, B C, C D, D A, each into 90° degrees; and to find the arcs of the meridians and parallels, proceed thus: divide the equator into its degrees; *viz.* 180 (as being indeed only half the equator); through these several divisions, and the two poles, describe arcs of circles, representing meridians, as B 10 D, B 20 D, &c.—How to find centres for describing those arcs, see under the word CHORD. See also *Geometrical Construction of the GLOBULAR PROJECTION*, infra.

Indeed the operation will be both more easy and accurate, if performed by a canon of semi-tangents.

Thus, by means of a sector, divide the equator A C into two lines of semi-tangents E A and E C, which will represent the degrees of longitude. Then with the secant of 80° , as a radius, describe the arc of the circle B 80 D, which represents a meridian cutting the plane of projection at an angle of 80° ; with the secant of 70° describe the arc B 70 D, which represents a meridian cutting the plane of projection at 70° ; and proceed in the same manner with the rest of the meridians, which are usually drawn at every 10° of longitude, as the parallels are at every 10° of latitude.

To describe the parallels, the meridian B D must be in like manner divided into 180 degrees; then through each of these divisions and the corresponding divisions of the qua-

drants A B, C B, describe arcs of circles. Thus shall we have parallels of all degrees, with tropics, polars, and meridians.

The parallels may be drawn with the tangents for radii, as the meridians are with the secants, 1010 representing the parallel of 10° , with the tangent of 80° , that of 20° with the tangent of 70° , &c. The ecliptic may be designed two ways; for its situation over the earth may either be such, as that its intersection with the equator may be over the place A; in which case the projection of its semicircles, from the first degree of Cancer, to the first of Capricorn, will be a straight line, to be determined by numbering $23^\circ 30'$ from A towards B, and from the extreme of that numeration drawing a diameter through E; which line will be half the ecliptic in this situation, and may be divided, as before, into degrees, to which the numbers, signs, &c. are to be affixed. But if the ecliptic be so placed, as that its intersection with the equator is over the place A, in the first meridian, its projection in that case will be a segment of an ellipsis: whereof two of the points are A, C; a third, that wherein the meridian 90 cuts the tropic of Cancer. The other points must be determined in the manner laid down above; *viz.* by taking the declinations and right ascensions of 15° of Aries, 1° of Taurus, 15° of Gemini, &c. For where the parallels, according to their several degrees of declination, cut the meridians, taken according to the several right ascensions, those points of intersection are the points of the 15° of Aries, &c. A curve line therefore being drawn, these will give the projection of the ecliptic.

Nothing then remains to complete the map, but to take the longitudes and latitudes of places from a table; and to set them off on the map; as was directed under the former method.

In this projection the whole surface of the earth may be represented in one map; if, instead of the plane of the first meridian, some other plane parallel to it, but very near the eye, be taken; for by this means the entire parallels and meridians will be described. But as this distorts the face of the earth too much, it is seldom used; and we rather make the two hemispheres in two distinct tables.

One great advantage in this projection is, that it represents the longitudes and latitudes of places, their distance from the pole and from the equator, almost the same as they really are on the earth. Its inconveniences are, that it makes the degrees of the equator unequal; being the greater as they are nearer the first meridian D A B, or its opposite B C D; and for this reason equal tracts of the earth are represented unequal; which defect may be in some measure remedied, by removing the eye far from the earth. And, lastly, the distances of places and situation, with regard to each other, cannot be well determined in maps of this projection.

Construction of Maps on the Plane of the Horizon, or wherein any given place shall be the centre or middle. Suppose, for instance, it is desired to have London the centre of the map. Its latitude we will suppose to be $51^\circ 32'$. The eye is placed in the nadir. The transparent table is the plane of the horizon, or some other plane, if it is desired to represent more than a hemisphere. Take then the point E (*fig. 6.*) for London; and from this, as a centre, describe the circle A B C D to represent the horizon, which you are then to divide into four quadrants, and each of these into 90 degrees. Let the diameter B D be the meridian, B the northern quarter, D the southern; the line of equinoctial east and west shews the first vertical, A the west, C the east, or a place of 90 degrees from the zenith in the first vertical. All the verticals are represented by right lines drawn from

the centre E to the several degrees of the horizon. Divide B D into 180 degrees, as in the former methods; the point in E B, representing $51^{\circ} 32'$ of the arc B C, will be the projection of the north pole, which note with the letter P. The point in E D, representing $51^{\circ} 32'$ of the arc D C (reckoning from C towards D), will be the projection of the intersection of the equator and meridian of London, which note with the letter Q; and from this, towards P, write the numbers of the degrees, 1, 2, 3, &c. As also from Q towards D, and from B towards P; viz. 51, 52, 53, &c. Then taking the corresponding points of equal degrees; viz. 99 and 99, 88 and 88, &c. about those, as diameters, describe circles, which will represent parallels, or circles of latitude, with the equators, tropics, and polar circles. For the meridians, first describe a circle through the three points A, P, C. This will represent the meridian 90 degrees from London. Let its centre be M in B D (continuing to the point N, which represents the south pole), P N being the diameter; through M draw a parallel to A C; viz. F H, continued each way to K and L. Divide the circle, P H N F, into 360 degrees, and from the point P draw right lines to the several degrees, cutting K F H L; through the several points of intersection, and the two poles P, N, as through three given points, describe circles representing all the meridians. The centres for describing the arcs will be in the same K L, as being the same that are found by the former intersection; but are to be taken with this caution, that for the meridian next B D N towards A, the most remote centre towards L, be taken for the second, the second from this, &c. The circles of longitude and latitude thus drawn, insert the places from a table, as has been directed.

Construction of Maps on the Plane of the Meridian.—This projection is taught by Ptolemy, and recommended by him as proper for that part of the earth then known. In this the equator and parallels are arcs of circles, and the meridians arcs of ellipses; the eye hanging over the plane of that meridian which passes over the middle of the inhabited world. But in regard the description of these ellipses is somewhat perplexing, and because this method seems calculated only for a part of the earth, it is not now used.

There is a second method, something akin to it, which represents the circles of latitude by right lines, and the meridians by arcs of ellipses; as must be the case, if lines be conceived to fall from the several points of each hemisphere perpendicularly on the plane of the first meridian, and the eye be supposed at an infinite distance from the earth, so that all the rays emitted from the places of the earth to it may be accounted parallels, as well as perpendiculars to the plane of the first meridian.

In his "Companion to a Map of the World," (London, 1794, 4^{to}.) Mr. Arrowsmith has offered the following remarks on projection; and as they are immediately connected with the subject of the construction of maps, we shall here subjoin them.

"As the earth is of a form approaching very near to a globe or sphere, it is evident that the only map which can truly represent the figure of the various countries, and their relative bearings and distances, must be delineated on the surface of a globe. But as globes of a size proper to exhibit a map sufficiently accurate, and containing all the information that is necessary or desirable, must be very bulky, and very expensive, it is necessary to have more portable and cheaper maps, executed upon a flat surface; these, since the art of copper-plate printing has been in use, have generally been made upon paper.

"It is obvious that such a map, wherein is attempted to

represent upon a plane surface that which is really spherical, must depart considerably from the truth; especially if it comprehends the whole, or a considerable portion of the world. It has, therefore, been an object which has engaged the attention of the most eminent geographers, to discover a projection (or arrangement of the proportional parts of the map) which should be liable to the fewest errors.

"The most natural method of representing a sphere upon a plane seems to be to divide it into two equal parts, and inscribe each of them in a circle: but as the equator and the polar axis, which intersect that circle at right angles, and makes one of the meridians, must be supposed equal in length to the half of the periphery (of which it is not quite two-thirds), it follows, of course, that the countries delineated upon or near these lines must be reduced to somewhat less than two-thirds of the size of the countries of equal extent, which lie at the extremity of the circle; and that the lines drawn to measure the latitude, which are parallel to each other, or nearly so, must, in order to preserve as nearly as possible their proportional angles at the points of intersection with the meridian, form segments of circles, of which no two are parallel or concentric.

"There may be as many different projections as there are points of view, in which a globe can be seen; but geographers have generally chosen those which represent the poles, at the top and bottom of the map: these, from the delineation of the lines of latitude and longitude, are called the stereographic, orthographic, and globular projections." See PROJECTION.

"I do not propose to detain the reader with a description of all the projections; some of which are so numerous (for the purpose of constructing of maps) as to deserve being consigned entirely to oblivion. But as projections of maps form a pleasing and instructive exercise, and, indeed, indispensably necessary to the right understanding of geography, by students, I shall describe the manner of constructing the map that accompanies this work; but first hint at the stereographic projection. (The great geographer, d'Anville, has constructed his map of the world upon this projection, adapting it to Cassini's system of the figure of the earth, which makes the polar diameter longer than the equatorial.) Among the various positions assignable to the eye, there are chiefly two that have been adopted, wherein the eye is placed either in the point D (fig. 7.) or removed to an infinite distance; and hence this projection is liable to the great error of distorting the form of the countries, represented upon it, much more than is necessary. The only advantage is, that the lines of latitude and longitude intersect each other at right angles.

"This being observed by that excellent astronomer, M. de la Hire (Hist. Acad. Sc. 1701), he invented a remedy for the inconvenience, by assigning to the eye a position at the point O (fig. 7.) the distance of which, from the globe at D, is equal to the right sine of 45° ; and hence the right line, G O, which bisects the quadrant B C, also bisects the radius E C, and produces the similar triangles O F G, and O E I; and thus the other parts of the quadrant B C, and, in like manner, of the whole semicircle A B C, are represented in the projection nearly proportional to each other, and to the eye perfectly so.

"This projection, as coming the nearest to a true representation of the globe, is called the "Globular Projection;" it is equal to the stereographic in point of facility, and vastly superior to it in point of truth.

"Geometrical Construction of the GLOBULAR PROJECTION.—From the centre C (fig. 8.), with any radius, as C B, describe a circle; draw the diameters A B, and 90, 90; (being careful to draw them at right angles), and divide them into

nine equal parts; likewise divide each quadrant into nine equal parts, each of which contains 10 degrees: if the scale admits of it, every one of these divisions may be subdivided into degrees: next, to draw the meridians, suppose the meridian 80° W. of Greenwich, we have given the two poles, 90, 90, and the point 80 in the equator, or diameter AB; describe a circle to pass through the three given points, as follows; with the radius 90 C, set one foot of the compasses on the point 90, and describe the semicircles XX and ZZ; then remove the compasses to the point 80 on the equator, and describe the arcs 1, 1, and 2, 2; where they intersect the semicircle, make the point as at 1 and 2, and draw lines from 2 through the point 1, till they intersect the diameter BA, continued, in E, then will E be the centre from which the meridian 90, 80, 90, must be drawn, and will express the meridian of 80° W. longitude from Greenwich. The same radius will draw the meridian expressing 140° W. longitude in like manner. Draw the next meridian with the radius CB, set one foot of the compasses in the point d, and describe the arcs *a a* and *b b*; then draw lines as before, which will give the point D, the centre of 90° W. longitude, and so of all the rest.

"The parallels of latitude are drawn in the same manner, with this difference, that the semicircles XX and ZZ must be drawn from the points A and B, the extremities of the equator." See *Construction of Maps, with the Eye in the Plane of the Equator*, supra.

"In the manner above-described, with great labour and exactness, I drew all the meridians and parallels of latitude to every degree in two hemispheres, which laid the foundation of the map now before us.

"We shall now drop a few hints on the advantage and disadvantage of Mercator's projection.

"A method has been found to obviate some of the difficulties attending all the circular projections by one, which, from the person who first used it (though not the inventor), is called "Mercator's Projection." In this there are none but right lines; all the meridians are equidistant, and continue so through the whole extent; but, on the other hand, in order to obtain the true bearing, so that the compass may be applied to the map (or chart) for the purpose of navigation, the spaces between the parallels of latitude (which in truth are equal, or nearly so) are made to increase as they recede from the equator in a proportion which, in the high latitudes, becomes prodigiously great.

"The great advantages peculiar to this projection are, that every place drawn upon it retains its true bearing, with respect to all other places; the distances may be measured with the nicest exactness by proper scales, and all the lines drawn upon it are right lines. For these reasons, it is the only projection in drawing maps or charts for the use of navigators." See CHART.

"Its only disadvantage is, that the countries in high latitudes are of necessity increased beyond their just size to a monstrous degree.

"Thus it appears, from this short view of three of the best modes of projecting maps of the world upon a plane surface, that each of those which have been more particularly described, is attended with advantages and disadvantages peculiar to itself; it is obvious, that the only means to acquire a just idea of the various countries upon such a surface, is by a comparison of two maps, one laid down on the Mercator's projection, and the other upon the best of the Circular projections." See PROJECTION.

MAPS, *General*, are the hemispheres; which are for the most part constructed stereographically.

MAPS, *Rectilinear*, are those wherein both the meridians and parallels are represented by right lines, which by the laws of perspective is impossible; in regard there can no such position be assigned to the eye and the plane, as that the circles both of longitude and latitude shall be right lines.

In the first method above laid down, the meridians are right lines, but the parallels are circles: in the fifth, the parallels are right lines, and the meridians ellipses. In all other perspective methods, both kinds of circles are curves: one method indeed must be excepted, wherein the meridians are right lines, and the parallels hyperbolas; as when the eye is placed in the centre of the earth, and the plane, through which it is viewed, is parallel to the first meridian: but this method is rather pretty than useful.

Rectilinear maps are chiefly used in navigation, to facilitate the estimate of the ship's way. See CHART.

Construction of particular Maps.—*Particular maps of large tracts*, as Europe, Asia, Africa, and America, are projected after the same manner as general ones; only let it be observed, that for different parts, different methods may be chosen. Africa and America, for instance, as the equator passes through them, cannot be conveniently projected by the first method, but much better by the second. Europe and Asia are most conveniently represented by the third; and the polar parts, or the frigid zones, by the first.

To begin then, draw a right line on your plane, or paper, for the meridian of the plane over which the eye is conceived to hang, and divide it into degrees, as before, which will be the degrees of latitude. Then from the tables take the latitude of the two parallels, which terminate each extreme. The degrees of these latitudes are to be noted in the meridian; and through them draw perpendiculars, bounding the map towards north and south. This done, meridians and parallels are to be drawn to the several degrees, and the places to be inserted, till the map is complete.

For particular Maps of less extent.—In maps of smaller portions of the earth, the geographers take another method. First, a transverse line is drawn at the bottom of the plane, to represent the latitude, wherein the southernmost part of the country, to be exhibited, terminates. In this line, so many equal parts are taken as that country is extended in longitude. On the middle of this same line erect a perpendicular, having so many parts as there are degrees of latitude between the northern and southern limits of the country. How big these parts are to be, may be determined by the proportion of a degree of a great circle to a degree of the parallel represented by the transverse line at bottom. Through the other extreme of this perpendicular, draw another perpendicular, or a parallel to the line at bottom, in which are to be seen as many degrees of longitude as in the lower line, and these, too, equal to each other, unless the latitudes happen to be remote from each other, or from the equator. But if the lowest parallel be at a considerable distance from the equinoctial, or if the latitude of the northern limit go much beyond that of the southern; the parts or degrees of the upper line must not be equal to those of the lower, but less, and that according to the proportion which a degree of the more northern parallel has to a degree of the more southern. After parts have been thus determined, both on the upper and lower line, for the degrees of longitude; right lines must be drawn through the beginning and end of the same number, which lines represent the meridians; then through the several

veral degrees of the perpendicular erected on the middle of the first transverse line, draw lines parallel to that transverse line: these will represent parallels of latitude. Lastly, at the points wherein the meridians of longitude and the parallels of latitude concur, insert the places from a table, as before directed. But though there are various modes of constructing these maps, they are, in general, defective, so as not to be applied with accuracy and facility to the purposes intended, in determining the courses or bearings of places, their distances, or both.

Suppose it were required to draw the meridians and parallels for a map of Britain. This island is known to lie between 50° and 60° of latitude, and 2° and 7° of longitude. Having therefore chosen the length of your degrees of latitude, you must next proportion your degrees of longitude to it. By the table of degrees of longitude corresponding to every degree of latitude, under DEGREE, you will find that in the latitude of 50° , the length of a degree of longitude is to one of latitude, as 39.054 is to 60; that is, a degree of longitude in lat. 50° , is somewhat more than half the length of a degree of latitude. The exact proportion may be easily taken by a diagonal scale; after which you are to mark out seven or eight of those degrees upon a right line for the length of your intended map. On the extremities of this line raise two perpendiculars, upon which mark out 10° of latitude for the height of it. Then, having completed the parallelogram, consult the table for the length of a degree of longitude in lat. 60° , which is found to be nearly one half a degree of latitude. It will be always proper, however, to draw a vertical meridian exactly in the middle of the parallelogram, to which the meridian on each side may converge; and from this you are to set off the degrees of longitude on each side. Then having divided the lines bounding your map into as many parts as can conveniently be done, to serve for a scale, you may by means of these set off the longitudes and latitudes with much less trouble than where curve lines are used. This method may always be adopted where a particular kingdom is to be delineated, and will represent the true figure and situation of the places with tolerable exactness. The particular points of the compass on which the towns lie with respect to one another, or their bearings, cannot exactly be known, except by a globe or Mercator's projection. Their distances, however, may thus be accurately expressed, and this is the only kind of maps to which a scale of miles can be truly adapted.

The Rev. T. Bowen has just published an excellent apparatus for describing the lines of longitude and latitude on maps, on a scale adapted for the use of schools. In like manner, these lines may be described on maps of any size with unerring accuracy.

The apparatus consists of a scale and a pair of compasses sufficiently large to describe the proposed lines, with a book to explain the method of using them. The short lines at each end of the scale represent the equators, the meridians, the north, the south, the east, and west lines graduated; from which the outlines of the maps are to be constructed, and the degrees laid down. The lines extending the whole length of the scale on the other side, contain the centres of the different circles which compose the lines of longitude and latitude mathematically found. The radius of each line to be described on the map, is the distance between that line and its corresponding number on the scale; consequently, by placing one limb of the compasses on the central point on the scale (when adjusted according to the directions given), extending the other to its corresponding number on the me-

ridian, and then moving it from east to west, the parallel of latitude is formed; from north to south through its corresponding number on the equator, and the line of longitude is described.

For an abstract of La Croix's paper on the projection of maps, see Pinkerton's Geography, vol. i. Introd.

For Maps of Provinces, or small tracts, as parishes, manors, &c. we use another method, more sure and accurate than any of the former. In this, the angles of position, or the bearings of the several places, with regard to one another, are determined by proper instruments, and transferred to paper. This constitutes an art apart, called *surveying*.

MAPS, *the Use of*, is obvious from their construction. The degrees of the meridians and parallels shew the longitudes and latitudes of places, and the scale of miles annexed, their distances; the situation of places, with regard to each other, as well as to the cardinal points, appears by inspection, the top of the map being always the north, the bottom the south, the right hand the east, and the left the west; unless the compass usually annexed shew the contrary.

MAPS of Estates, in Agriculture, such plans or outlines of lands as are necessary to direct their management in the most easy and economical manner. In an useful work on "Landed Property," it is advised that the different distinct parts or farms into which they are divided, should be outlined, coloured, and introduced on a general map, as well as each separately delineated, more particularly on a small pocket one, so as to shew the farms with distinctness, or the lands intended to be laid into them, with the wood-lands, waters, &c. &c. that are in hand. The pocket maps should exhibit at once the outlines, the names, and the contents of the different fields, or pieces of land of which they are severally constituted, which by being coloured according to occupancy, the several fields of the existing farms (or intermixed parts of farms intended to be united), though scattered, may be readily distinguished. And "if separate columns of contents be indorsed on the backs of the maps, one of them of the intended farm, the other of the existing farms or parts of farms, with their totals subjoined; all the doubts and perplexities which are wont to arise on large estates, from the intermixture of farm-lands, will be avoided."

And these maps of farms should be of a portable size, as ten inches by eight, and be bound up in volumes corresponding to the general maps; so that the superintendent-manager in going over any part of the estate, may have with him the maps that belong to it. Each map should be folded double, and be hung in loosely within flexible covers, by a guard or slip of paper pasted on the back, in order that when opened each may lie flat and fair, and be conveniently portable when shut.

MAPS, *Geognostic*. The idea of exhibiting in maps, by means of signs or illumination, the principal geognostic features of a given tract of country, the aspect of its surface, the nature of its rocks, their alternation and relative position, is as new as the science which teaches us to distinguish from each other the manifold materials that compose the crust of the earth as far as we are acquainted with it. Several methods have been lately adopted for accomplishing the above object; of all which that of colouring the spaces occupied by the different rocks appears by far the most convenient. It is this method which has been improved and carried to a high degree of precision by the celebrated Werner, who has happily removed all those obstacles which hitherto prevented its general adoption. We are indebted

to professor Jameson for an account of the Wernerian method of colouring maps, communicated in the first volume of the "Transactions of the Wernerian Society" lately published.

The following rules should be observed in illuminating maps for the above purpose: 1. In every case such colours are to be used as will allow the ground-work of the map or delineations of the mountains to appear through them distinctly. 2. The colours should agree as nearly as possible with nature; they should correspond with the most common colour of the rock, or, at least, differ from it as little as possible, and agree with the transition suite of the colours. 3. The use of all bright colours must be avoided. 4. The colours must not be too pale or too deep, and they ought to be laid on as much as possible of the same intensity: perfectly dark and light coloured rocks are exceptions to this rule. 5. The colours of mountain-rocks must form suites or transitions, in order to express the transitions of the rocks to each other; at the same time they must be sufficiently distinct from each other.

The following colours are employed by Werner for distinguishing the particular rocks:—quartz; reddish-white, inclining a little to yellow:—topaz-rock; pale brick red:—granite; pale cochineal red, approaching carmine-red:—white-stone; pale flesh-red:—gneiss; lilac-blue:—mica slate; pearl-grey:—primitive clay-slate; greenish-grey, approaching to blue:—alum-slate; pale blueish-black, approaching to grey:—fletz-slate; deep ash-grey:—grey-wacke-slate and grey-wacke; greenish-grey, passing into yellow:—trap-rocks, such as granular primitive trap, green-stone, green-stone slate, hornblende slate, blackish-green inclining to blue:—basalt; greenish-black:—porphyry-slate; pale greenish-black:—amygdaloid; pale greenish-black, slightly inclining to brown:—serpentine; pale pistachio-green:—talc and chlorite-slate; pale grass-green:—porphyry; pale reddish-brown, slightly inclining to yellow:—sienite; pale reddish-brown, inclining to blueish, that is, clove-brown passing into blueish-red:—granular primitive lime-stone; pale Berlin-blue:—compact primitive lime-stone; smalt-blue, faintly inclining to red:—transition lime-stone; indigo-blue, slightly inclining to grey:—fletz-lime-stone; pale blueish-grey:—chalk; blueish-white:—calcareous tuf; smoke-grey:—gypsum; pale sky-blue:—rock-salt, and rocks from which salt-springs issue; pale verdigris-green:—coal-formation; pale blackish-brown, approaching to yellowish-brown:—alum-earth and brown coal; liver brown:—conglomerate and clay-stone; pale orange-yellow, slightly inclining to reddish-brown:—sand-stone; straw-yellow:—loam and clay; yellowish-grey passing into ochre-yellow:—iron-clay and calamine; pale ochre-yellow:—turf and peat; liver-brown streaks:—bog-iron ore; ochre-yellow streaks. All these rocks may, likewise, be distinguished by particular signs or symbols; for which, if they should be deemed useful, we refer to the Wernerian Transactions.

Not only particular rocks, but also formation suites, may be represented in colours. Thus, the slate formation suite will be red shaded into blue, the blue into grey; this latter into green, and the green into yellow. The inflammable fossils, subordinate to these formations, will be dark brown. The lime-stone formation suite will be blue, which will pass into grey, and lastly into white. The salt and gypsum formation suites, which are allied to the preceding, will be greenish-blue and blueish-green; the trap suite, greenish-black and blackish-green, shaded into blue; the porphyry suite, light brown; the talc and serpentine suite, pale yellowish-green.

The relative positions of the different rocks, Werner ex-

pressed in the following manner: boundaries of superimposed rocks are to be marked with a broad line of the same colour as the rock, only darker; and where we are uncertain as to the superposition of the rock, the junction is to be merely streaked. Beds, when they appear at the surface, should have their boundaries distinguished by a broad, but darker, line of the same colour as that of the rock of which they are composed. When the beds are inclined, the lower side should be marked with a broad line of the same colour as the bed itself; but its upper side by a broad dark line of the colour of the rock that rests on it.

Veins are represented by lines drawn in the direction of the veins of the district. Metalliferous veins should be pointed out by red lines; and veins filled with mountain-rocks, by lines of the same colour as the rock of which they are composed.

The dip of the strata is expressed by black coloured arrows, whose length should be in proportion to the angle of inclination, and their direction to the point of the compass towards which the strata dip or incline. When the strata are vertical, or under any angle from 90° to 80° , they are marked by two cross lines, thus \times ; horizontal strata, or strata under any angle from 0 to 10° , by two lines crossing each other at right angles, and having a head of an arrow at each extremity. The intermediate angles from 80° to 10° are marked by simple arrows, one-eighth, one-fourth, and half an inch in length. The arrow one-eighth of an inch in length intimates that the strata are inclined at any angle between 30° and 60° ; the arrow one-fourth of an inch in length, that the strata are inclined at any angle between 60° and 40° ; the arrow half an inch in length, that the strata are inclined at any angle between 40° and 10° . The first or shortest arrow is meant to point out strata inclined under an angle of 70° ; the second arrow, strata under an angle of 50° ; the third arrow, strata under an angle of 25° . Probably, according to Mr. Jameson, an equally convenient mode would be, to mark the angle of inclination alongside the arrow, and proportion its size to the length of the map. Thus, if the map were on a large scale, the arrow might be three-quarters of an inch long; if on a smaller scale, half an inch, or even one-quarter of an inch in length. The highest points on a mountain-range, Werner distinguishes by a cross, $+$; a level, by a figure resembling a door, Π ; and a shaft, by a small parallelogram, \square .

MAPANA, in *Geography*, a lake of Thibet, from which the Ganges is said to issue. The head of this majestic river is composed of two streams, which run westward; and the southernmost of these branches runs through two lakes, the first of which is named Mapana, and the second "Lanken."

MAPANIA, in *Botany*, a name in Aublet, of whose derivation or meaning no account is given, but which is retained by Jussieu and Vahl. *Aubl. Guian.* v. 1. 47. *Vahl. Enum.* v. 2. 391. *Juss.* 27. *Lamarck Illustr.* t. 37.—Class and order, *Triandria Monogynia*. *Nat. Ord. Calamariae*, Linn. *Cyperoideae*, Juss.

Gen. Ch. *Cal.* Involucrum many-flowered, of three very large, spreading, equal, ovate, acute, smooth leaves, much longer than the flowers. Perianth inferior, of six ovate, acute, concave leaves. *Cor.* none. *Stam.* Filaments three, inserted into the receptacle, capillary, longer than the calyx; anthers oblong, quadrangular, of two cells. *Pist.* Germen ovate, superior; style thread-shaped, equal to the stamens; stigmas three, awl-shaped. *Peric.* none. *Seed* one, roundish, naked.

Ess. Ch. Involucrum of three leaves. Perianth inferior, of six leaves. Corolla none. Seed one, naked.

1. *M. sylvatica*. *Aubl.* t. 17.—Native of marshy forests, about

about the rivers Aroura and Orapu in Guiana, where Aublet found it flowering in June. One of his specimens is before us. Root perennial, creeping, firm, throwing up several simple, triangular stems, about two feet high, rough with minute harsh points or prickles, and clothed at the base with several sheathing, imbricated, membranous, reddish-scales or leaves. The rest of the stem is naked, but its top is crowned with the three spreading involucreal leaves, each five or six inches long, obovate, pointed, ribbed, entire, smooth, green, and foliaceous, in whose centre is stationed a round sessile head of several flowers. Vahl, who had examined a specimen, justly remarks, that the leaves of the calyx are not toothed, as Aublet describes them, but entire.

MAPELLA, in *Geography*, a town of Italy, in the department of the Mincio.

MAPLE, in *Botany*. See ACER.

MAPLE Tree, in *Agriculture*, the common name of a tree of the deciduous kind, cultivated for the purposes of timber and ornament in plantations and other grounds. There are several species and varieties of this tree, as the great maple or sycamore, the common or smaller maple, the ash-leaved Virginia maple, the Montpelier maple, the plane-tree like Norway maple, the scarlet flowering maple, the sugar maple, the Tartarian maple, the Italian maple, the Pennsylvanian mountain maple, and the Cretan maple.

And there are two varieties of the great maple or sycamore, one with broad leaves and large keys, the other with variegated leaves: the latter, when blended in large plantations, affords a pleasing variety. This tree is frequently known by the name of *sycamore*, *mock plane*, and *plane tree*. See SYCAMORE.

The common maple is a tree of much humbler growth than the great maple, and by no means so ornamental; it may, however, be useful in extensive plantations and pleasure grounds. It is also very good for timber, being close in the grain of the wood. When cut down, it affords an excellent underwood.

The ash-leaved maple should be made use of in situations that are not much exposed to the winds, as it is said to be apt to be split by them. The wood is soft and brittle, and of course less useful as timber.

The Montpelier maple is chiefly useful for the variety it affords in ornamental plantations.

And the Norway maple is principally useful for affording shelter, and also as a timber tree. There are two varieties, one with variegated or striped leaves, and the other with cut leaves.

There are two varieties of the scarlet-flowering maple, the Virginian scarlet-flowering maple, and sir Charles Wager's maple. Both of them are chiefly propagated for the sake of the flowers, which are of a scarlet colour. The sort called sir Charles Wager's, produces larger clusters of flowers than the other, on which account it is in more estimation.

In America, the inhabitants tap the sugar maple in the spring, and boil the liquor, which affords an useful sugar. The sycamore, the ash-leaved, and the Norway maples also abound with a saccharine juice, from which sugar might probably be prepared with advantage in some situations.

The Italian maple is common in many parts of Italy, and is a lofty tree, and, from its having a spreading head, adorned with large and beautiful foliage, deserves the attention of ornamental planters. It may be also useful as a timber tree, in some cases.

The Cretan maple is only useful as an ornamental tree. There is a variety of it, in which the leaves continue green

most part of the year, when sheltered, and which is denominated the evergreen Cretan maple.

It may be noticed, that all the sorts and varieties of the maple are of easy cultivation; each being capable of being raised by seed, and many of them by layering, cuttings, and budding. They thrive well in moist soils and situations, provided they be not too moist; the common sorts succeeding the best in such as are deep and inclined to moisture, but not hard or stiff; and the American kinds in those that have a dry and rather close state of mould or soil. In raising them in the first method, as the seeds do not, in all the sorts, ripen well in this country, the best way is to procure them from the places where they grow naturally. A cool shady place is the most suitable for this purpose. The mould being made fine, and nursery beds marked out four feet wide, with length proportionate to the quantity, in these the seeds are to be regularly sown in the autumn, sifting over them the finest mould to the depth of half an inch. When the plants are come up, they must be kept clean from weeds, and frequently watered during summer. In the spring following, the strongest may be drawn out and planted in nurseries, in rows two feet asunder, and at the distance of a foot from each other in them, leaving the others to gain strength. In the second spring, these also must have the same culture; and they may remain in the nursery, without any other trouble than keeping the ground clean in the summer, digging between the rows in the winter, and taking off all strong and irregular side-shoots, till they are fit to be planted out. The trees raised in this way grow faster, and arrive at greater heights, than those from layers; but they do not in general produce such quantities of flowers, which makes the latter mode more eligible for those who want these plants for low shrubby uses. In these cases, they should always have four or five years growth before they are finally planted out. It is, however, advised by some, that the seeds of the common or Norway maples should not be put into the soil immediately after becoming ripe, but be dried and preserved in sand till February or March, as the season may prove favourable, when they may be sowed in drills or beds eighteen inches broad, with alleys the same width, and covered three quarters of an inch thick with mould. In the following February or March, the alleys should be dug, and the roots of the plants cut about five inches under ground, which may be easily performed by means of a sharp spade, drawing the plants out where too thick. These may be replanted in any good mellow soil, in rows eighteen inches asunder, and eight or nine inches from each other in the rows. In October, when the plants in general will be about two feet high, both the seedlings and those that were transplanted should be raised, shortening their tap-roots, cutting off any cross lateral branches, and removing them into rows two feet and a half apart, and fifteen inches distant in them, in order that they may continue for a year or two. Remove them again at the same season the succeeding year, and plant them in rows five feet asunder, and two and a half from each other, that they may continue four years. These will now be from twelve to fifteen feet high; and if required of a still larger size, they may be removed, and planted again eight or ten feet asunder; when, any time after two and not exceeding eight or ten years, they may be finally planted out where they are to remain. The use of removing these trees frequently when young is, that they are apt naturally to grow with tap-roots, which this management prevents, and makes the plants root better, and become more easy and certain in their growth, when transplanted at a large size. The timber sorts are best raised from the seeds, without being removed at all. Though all
the

the species are capable of being propagated by layers, it is never practised for the common maple. In this method the young shoots may be laid down at any time, in the autumn, winter, or early in the spring; but the first is probably the best. By the same time in the following year they will have struck root, and have become good plants, when the strongest may be set out in the places where they are to remain; while the weakest may be planted in the nursery, in the same manner as the seedlings, for a year or two, in order to gain strength.

But in propagating by cuttings, though all these trees are capable of it, it is a method chiefly practised on the ash-leaved and Norway maples, as they take root this way more readily. The cuttings should be taken from the bottom part of the last year's shoots early in October, and be planted in rows in a moist shady place. In the spring and summer following they should be watered, as often as dry weather makes it necessary, and be kept perfectly clean from weeds. In the autumn they will be fit to remove into the nursery; though if the cuttings are not planted too close, they may remain in their situations for a year or two longer, and then be finally set out without the trouble of being previously planted in the nursery. These trees are also to be raised by budding and grafting, but as the other methods are more eligible, these are seldom or ever practised, except for the variegated sorts and the large broad-leaved kind. The latter indeed is to be continued in no other way than by budding it on stocks of the common sycamore; as the seeds, when sown, afford only the common sycamore. But the seeds of the variegated kinds produce variegated plants; which renders the propagation of these sorts very expeditious where plenty of seed can be had. But where it is not to be obtained, in order to propagate these varieties, recourse must be had to budding; in performing which some plants of the common sycamore one year old, are to be taken out of the seed-bed and placed in the nursery in rows a yard asunder, and about a foot and a half distant from each other in the rows. The ground must

be kept clean from weeds all summer, and be dug, or, as the gardeners call it, *turned* in the winter; and the summer following the stocks will be of a proper size to receive the buds, which should be taken from the most beautifully striped branches. The best time for this operation is about August; as, if it is done earlier the buds will shoot the same summer, and when this happens a hard winter is apt to kill them. Having budded the stocks the middle or latter end of August, the eyes, or buds, being inserted on that side the stock which faces the north towards the beginning of October, the bafs by which it was tied may be removed, as it will begin to pinch and confine the bark as well as the bud too much. In the spring, just before the sap begins to rise, or the trees begin to shoot, the head of the stock should be cut off in a sloping direction just above the inserted; by these means, and that of rubbing off such shoots as come from the stocks, the shoot from the inserted bud will be rendered more strong and healthy. The trees thus raised may remain in their situations for a year or two longer, or be transplanted into the places where they are intended for, in the autumn or spring following; care being constantly taken to keep the land between the rows well dug, so as to prevent their being injured by the growth of coarse weeds, and the side buds trimmed from their stocks occasionally.

In respect to the time of planting, the autumn season is upon the whole the best time for planting these and other deciduous trees, when they are strong and well rooted; yet when very young they are apt to be injured by frosts, and

to be thrown out of the ground in severe winters, when planted in that season of the year. In such cases the spring is better.

MAPLE Sugar, a kind of sugar made from a species of the maple, called by Monsieur Sarazin, *acer Canadense sacchariferum fructu minori*. M. Sarazin, a physician at Quebec, intending to inquire at large into the nature of this sort of sugar, observed that there were four species of maple common in the places where it was made, all which he sent over to the garden at Paris. One of these species, distinguished from the rest by the smallness of its fruit, is called the sugar-maple; this grows to sixty or eighty feet high, and its juice, which is very redundant in the months of April and May, is easily made into a very good sugar. They procure this juice from the tree by piercing a hole into the trunk, and placing vessels to receive it. This juice, being evaporated, yields about one-twentieth part of its own weight in pure sugar. A middle-sized tree, of this species, will yield sixty or eighty pints of this juice, without receiving any damage as to its growth; and much more than this may be drawn, but then the tree manifestly suffers for it.

M. Sarazin observed some very remarkable particulars in regard to the saccharine quality of this juice, without which it never had it in the proper perfection. 1. The tree, at the time that the juice is drawn out, must have its bottom covered with snow; and if it is not naturally so, the Indians know so well the necessity of it, that they always bring snow from elsewhere, and heap it up round it. 2. This snow must afterwards be melted away by the sunshine, not gradually thawed by a warm air. 3. There must have been a frosty night before the opening of the hole in the trunk. It is remarkable that these circumstances are such as custom and experience alone could have pointed out, since they seem contrary to reason; and so it is in many of the operations in chemistry, where the most seemingly rational means fail, while those which should seem quite contradictory to reason succeed. It is observed, that if the juice of the maple be not in a condition to become saccharine while the snow lies at its root unthawed, that it almost immediately becomes so on the melting of the snow, and its penetrating into the earth. Mem. Acad. Par. 1730.

The juice of the maple, unboiled, has been drank as an antiscorbutic; the sugar and molasses, which are said to be less sweet than those extracted from the sugar-cane, are supposed to be more medicinal in disorders of the breast.

MAPLE Islands, in *Geography*, two small islands of America, in lake Superior, near the E. coast. N. lat. $46^{\circ} 44'$. W. long. $84^{\circ} 54'$.

MA-POU-HOTUN, a town of Corea; 46 miles E.N.E. of Peking.

MAPOURIA, in *Botany*, Aublet. Guian. v. 1. 175. t. 67, a shrub of Guiana, found by Aublet on the banks of the river *Sinémaré*, flowering in September. It is called by the natives *Maypouri-crabi*, because the *maypouris*, or wild cattle, are fond of the leaves and branches, and thence the above name was constructed. The root throws up many soft, brittle, juicy stems, about eight or nine feet high, clothed with a greenish bark. Leaves opposite, each pair crossing the next, oval, pointed, entire, pliable, smooth and shining, with one rib, and numerous transverse parallel veins; each leaf eight inches long at molt, and about half as broad, supported by a footstalk an inch in length. *Stipulas* intrafoliaceous, in pairs, ovate, large, deciduous. *Panicle* terminal, trichotomous, many-flowered, with opposite minute *bracteas* at its subdivisions. *Flowers* small. *Calyx* superior, of five teeth. *Corolla* white, of one petal,

its limb in five segments, about twice the length of the tube. *Stamens* five, as long as the limb, inserted into the tube between the segments. The mouth of the tube is beset with white hairs. *Germen* inferior, oval; style simple, as long as the stamens; stigma of two oblong lobes. *Fruit* unknown.

Jussieu, Gen. 207, presumes this plant to be of the same genus with the *Simira* of Aublet, t. 65, and perhaps with his *Palicourea*, t. 66. The latter is the *Stephanium* of Schreber, of which we shall speak in its proper place, and was referred by Solander to *Mussaenda*. They appear to us very near to *Ptychotria*, at least to some plants referred to that genus. They all belong to the *Pentandria Monogynia* of Linnaeus, and to the seventh section of Jussieu's great natural order of *Rubiaceae*.

MAPPARIUS, an officer among the Romans, who in the public games, as those of the circus, and of the gladiators, gave the signal for their beginning, by throwing an handkerchief (*mappa*) which he had before received from the emperor, consul, prætor, or other supreme officer, then present.

MAPPIA, in *Botany*, received its name from Schreber, in memory of Mark Mappi, M.D. formerly a physician and botanist at Strasburgh, who in 1691 published a 12mo. catalogue of the plants in the public garden of that university. He also published, as Professor, some inaugural dissertations on tea, coffee and chocolate, and on the rose of Jericho. His *Historia Plantarum Alsaticarum* appeared in 1742, after the author's death, by the care of Dr. Ehrmann, of the same place. This is a quarto volume of 335 pages, with a few plates, disposed in alphabetical order. Mappi died in 1701, at the age of 69. Schreb. Gen. 806. Mart. Mill. Dict. v. 3. (Soramia; Aubl. Guian. 552. t. 219. Juss. 433. Lamarck Illustr. t. 463.)—Class and order, *Polyandria Monogynia*. Nat. Ord. uncertain, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, roundish, concave, permanent segments, coloured on the inside. *Cor.* Petals five, roundish, spreading, scarcely longer than the calyx, supported by short claws. *Stam.* Filaments numerous, (about 60,) the length of the corolla, capillary, dilated upwards, inserted into the receptacle; anthers ovate. *Pist.* *Germen* superior, globose; style cylindrical, incurved; stigma capitate. *Peric.* Berry ovate, of one cell. *Seed* solitary, large, ovate, involved in a thick viscid tunic.

Ess. Ch. Calyx of five leaves. Petals five. Berry superior, of one cell. Seed solitary, involved in a viscid tunic.

1. *M. scandens*. (Soramia guianensis; Aubl. Guian. t. 219.)—Found by Aublet on the banks of the river Sinémari, bearing flowers and fruit in May. The stem is shrubby, with tuberculated branches, and twines about the trunks of trees, climbing to their summits, where the ultimate shoots become very long and pendant, bearing alternate, obovate, entire, smooth, fleshy leaves, six inches long at the utmost, and about half as wide, each supported by a footstalk an inch in length. Flowers white, in small, lax, axillary or lateral, corymbose clusters. Stamens about 60, according to Aublet's French description, which is always the most authentic; the Latin one, made from it by other hands, says 160, an error which Schreber has incautiously adopted. Berry red, the size of a cherry, crowned with the permanent style; its substance firm, fleshy, slightly acid. The tunic of the seed is thick, white and viscid. Permanent calyx fleshy and deep red.

MAPROUNEA, the barbarous name in Aublet, who gives no account of its meaning or derivation, for a small tree of Cayenne, the *Aegopricon betulinum*, Linn. Suppl. 63.

413. Sm. Plant Ic. t. 42. (*Maprounea guianensis*; Aubl. Guian. 807. t. 342.) See *ÆGOPRICON*. We beg leave to correct one of our predecessors as to the origin of this name. It seems to be formed of *αιξ*, a goat, and *κοπρος*, dung, in allusion to the shape of the fruit, which resembles the dung of goats or sheep. It ought rather therefore to have been written *Aecopricon*.

MAPUNCO, in *Geography*, a town of Africa; in the kingdom of Angola.

MAQUALBURY, a river of Africa, which runs into the Atlantic, about 10 miles S.E. from the Scherbro. N. lat. 6° 50'. W. long. 10° 30'.

MAQUEDA, a town of Spain, in New Castile; 32 miles S.W. of Madrid.

MAQUILAPA, a town of Mexico; 15 miles S.W. of Chiapa.

MAR, in *Rural Economy*, a provincial term signifying a river or small lake.

MARA, in *Mythology*, a name of the Hindoo god of love, *Kama*; which see.

MARA, *Madame*, in *Biography*, born Schmeling, a native of Germany, arrived in England in 1760, with her father, during childhood, when she acquired a very correct pronunciation of our language, which is never done by foreigners but in youth. She could not be more than nine or ten years old when she came hither, yet she was then a notable performer on the violin; and as there were several children at that time in London of uncommon proficiency on different instruments, a concert was made for them at the Little Theatre in the Haymarket, in which they severally displayed their talents; Baron and Schmeling on the violin; Miss B. on the harpsichord, and Cervetto on the violoncello.

After staying two or three years in England, and, we believe, performing on the violin in different parts of the kingdom, to the great surprise and pleasure of the lovers of music, she returned with her father to Germany, and we heard no more of her till the year 1771, when we received from a very intelligent musical friend at Hambro' the following letter.

"At Berlin there is now a German opera singer, that astonishes every one who hears her. People who have been a long time in Italy, and who have formerly heard Faustina, Cuzzoni, and Altrua, assure me that she surpasses them all. Indeed, when I heard her at Leipzig, two years ago, I was enraptured. I never knew a voice so powerful, and so sweet at the same time; she could do with it just what she pleased. She sings from G to E in *altissimo* with the greatest ease and force, and both her *portamenta di voce*, and her volubility are, in my opinion, unrivalled; but when I heard her, she seemed to like nothing but difficult music. She sung at sight, what very good players could not play, at sight, on the violin; and nothing was too difficult to her execution, which was easy and neat. But, after this, she refined her taste, inasmuch that she was able to perform the part of "Tisbe," in Haffé's opera, which requires simplicity and expression, more than volubility of throat; and in this she perfectly succeeded, as Agricola, the translator of Tosi's "Arte del Canto," and our best singing master in Germany, assures me. The king of Prussia, a great connoisseur, was astonished at it. Her name is Schmeling, she is about twenty-four years of age, and was in England, when a child, where she played the violin; but she quitted that instrument, and became a singer, by the advice of English ladies, who disliked a female fiddler." The next year, in travelling through Germany, this account was fully corroborated by several intelligent musicians who had heard her; and previous to our arrival at Berlin, we were informed that his Prussian majesty,

majesty, who, at first, with difficulty was prevailed on to hear "a German singer," exclaimed, "I should as soon expect to receive pleasure from the neighing of my horse." However, after his majesty had heard her sing one song, he was said to have fought among his manuscript music for the most difficult airs in his collection, in order to try her powers, as much as to gratify his own ear; but she executed, *at sight*, whatever he commanded her to perform, in all styles, as well as if she had practised each of these compositions during her whole life.

When, afterwards, we had an interview with her at Berlin, we find in our journal the following account of her person: "She is short, and not handsome, but is far from having any thing disagreeable in her countenance; on the contrary, there is a strong expression of good nature impressed upon it, which renders her address very engaging. Her teeth are irregular, and project too much, yet, altogether, her youth and smiles taken into the account, she is rather agreeable in face and figure."

We found that she had preserved her English; indeed she sometimes wanted words, but having learned it very young, the pronunciation of those which occurred was perfectly correct. She was prevailed upon by a friend, who had procured us this interview, to sing soon after our entrance. She began with a very difficult *aria di bravura*, by Traetta, which we had heard before at Mingotti's in Munich. She sung it admirably, and fully answered the great ideas which we had formed of her abilities, in every thing but her voice, which was a little cloudy, and not quite so powerful as we expected. However, she had a slight cold and cough, and complained of indisposition; but with all this, her voice was sweetly toned, and she sung perfectly well in tune. She has an excellent shake, a good expression, and a facility of executing and articulating rapid and difficult divisions, that is astonishing.

Her second song was a *larghetto*, by Schwanenburg, of Brunswick, which was very pretty in itself; but she made it truly delightful by her taste and expression: she was by no means lavish of graces, but those she used were perfectly suited to the style of the music, and idea of the poet.

After this, she sung an *andante*, in the part which she had to practise for the ensuing carnival, in Graun's "Merope;" and in this acquitted herself with great taste, expression, and propriety.

In a second visit to Mademoiselle Schmeling, she favoured us with several songs of uncommon rapidity and compass; her powers in these particulars were truly astonishing; but we found that she was frequently compelled to abuse those powers by the airs which were given her to execute, in which she had passages that degraded the voice into an instrument; indeed such as a player of taste would be ashamed to execute on any instrument. Breaking a common chord into common *arpeggios* of no meaning, such as may be seen in the second allegros of Corelli's first and third solos, does not seem to reflect much honour, either upon a composer or performer. Geminiani, in transforming these solos into concertos, omitted these violin *solfeggios* or exercises for the hand in private practice.

We found in this second visit to Mademoiselle Schmeling, a little want of brightness in the middle of her voice; and we then imagined it possible for her still to improve in singing adagios, though not in the execution of allegros. She did not then indeed seem to be placed in the best school for advancement in taste, expression, and high vocal finishing.

In the spring of 1784, Mademoiselle Schmeling arrived in England under the name of Mara, having been some time married to a performer on the violoncello, in the service of

prince Henry, brother to the king of Prussia, with whom she was connected in 1772, when we saw her at Berlin. There had been a correspondence opened between this admirable singer and the proprietors of the Pantheon, who wished much to engage her as a successor to the Agujari; but the king of Prussia would not let her quit his capital; and after she had executed an article which engaged her in the service of the Pantheon, and money had been remitted to her to defray the expences of her journey, on his Prussian majesty discovering that she intended to quit his service *a la scurdine*, he had her arrested and thrown into prison; and it was with extreme difficulty that she contrived, by means of our ambassador, sir James Harris, to let the proprietors of the Pantheon know that she could not fulfil her engagement, and entreated them, for God's sake, not to write to her any more. She, however, very honestly returned the money that had been advanced to her by the proprietors of the Pantheon.

At length, however, she obtained her dismissal, and engaged herself to perform six nights at the Pantheon; 1784 was not an auspicious year for the Pantheon. The dissolution of parliament and general election happening soon after her arrival, the audiences to which she sung were not very numerous, nor had her performance the effect it deserved, till she sung at Westminster Abbey; where she was heard by near three thousand of the first people in the kingdom, not only with pleasure, but extacy and rapture.

In 1786, the opera regency, after a bankruptcy, being settled, and sir John Gallini invested with the power of ruining himself and others, "Didone Abbandonata," a pasticcio serious opera, was brought out previous to the arrival of Rubinelli, and had considerable success. But this must be wholly ascribed to the abilities of Madame Mara, who sung on our opera stage for the first time. Indeed, she was so superior to all other performers in the troop, that she seemed a divinity among mortals. The pleasure with which she was heard, had a considerable increase for her choice of songs; which, being in different styles by Sacchini, Piccini, Mortellari, and Gazzaniga, were all severally encored during the run of the opera; a circumstance which we never remember to have happened to any other singer, except Manzoli.

The manner in which she sung Handel's oratorio music in Westminster Abbey, and continued to sing it elsewhere, had gained her more applause and favour with the English public, than her astonishing execution.

This great vocal performer, except a few short excursions to the continent in summer, continued to reside in England, and to enjoy the favour and admiration of the public, till the latter end of 1802; when she returned to Germany, and is said to have been received at Berlin, and heard with the same enthusiasm which she had excited 30 years ago. We have done ample justice to the talents of this extraordinary singer on many occasions. But we cannot quit this article without a few discriminative reflections, not to injure or extend her fame, but to manifest our sincerity as well as candour in drawing characters.

We have never been able to discover of whom the Mara, after quitting the violin, learned to sing; but we are inclined to think that it was not of an Italian master; and that if it was of a German, it was of an instrumental performer. Perhaps the whole of her study in singing was to imitate the instruments of great performers. In the probable state in which she had traveled with her father, she could have had no opportunities of hearing fine Italian singing by performers of the first order. And it has often been observed by those accustomed to exquisite Italian singing, that her cadences, expression, and execution, however excellent, favoured more

of instrumental perfection than vocal. Her recitative was not spoken with Italian energy; and when we consider what a good performer she had been, early in life, on the violin, and what a good player she afterwards became on the piano-forte; or, in other words, what an excellent musician she was, and with what facility she could execute all kinds of difficulties, we have been often surprized at the little novelty, variety, and refined taste, there was in her clothes. Indeed it will perhaps be said, that she brought here, and left behind her, in this country, scarcely a new vocal passage; as all other great singers, such as in our own memory, Mingotti, Elish, Manzoli, Pacchierotti, Rubinelli, and Marchesi had done; but all these remarks only confirm old proverbs, that neither human nature, nor human art, are ever to be perfect, and that we cannot have every perfection in one and the same individual.

MARA, in *Geography*, a mountain of Malacca, near the Straits. N. lat. $1^{\circ} 55'$. E. long. $104^{\circ} 39'$.

MARASCIAN, a town of Turkestan, on the SIRR; 130 miles S.S.E. of Andugar.

MARABAD, a town of Persia, in the province of Segestan; 120 miles N.N.E. of Zareng.

MARABEA, a town of Arabia, near the Red sea, formerly a sea-port, but since the harbour has been filled up, most of the inhabitants have settled at Loheia; eight miles N. of Loheia.

MARABONA BAY, a bay on the N. coast of Jamaica. N. lat. $18^{\circ} 31'$. E. long. $77^{\circ} 21'$.

MARABOU, an inlet of the harbour of Alexandria, in Egypt, situated at its western extremity, commanding one of the channels, and separated from the continent by a range of rocks 140 yards in extent. The length of the inlet is not above 300 yards, and its breadth 150. The French, during their abode in Egypt, constructed a strong regular fort on this inlet round a tower, which was formerly a mosque.

MARACA, a small island in the Atlantic, near the coast of Guiana. N. lat. 2° . W. long. $51^{\circ} 26'$.—Also, a town of South America, in the government of Caraccas; 50 miles S.W. of Leon de Caraccas.

MARACAGUACO, a branch of the Amazons' river, which joins the main stream; 40 miles S.W. of Pauxis.

MARACAJA, in *Zoology*. See *FELIS Tigrina*.

MARACAIBO, a province of South America, in the government of Caraccas, surrounding a lake of the same name; bounded on the N. by the Caribbean sea; on the E. by Venezuela; on the W. by the government of Rio de la Hache, dependent on the vice-royalty of New Granada; and on the S. by Varinas, and the kingdom of Santa Fé. This province covers but a small extent from E. to W., but stretches more than 100 leagues towards the south. The soil of Maracaibo is, for a certain distance from the capital, ungrateful; on the eastern bank the lake is dry, unhealthy, and unfruitful. On the west bank of the lake, the land does not begin to be fertile at more than 25 leagues to the south of the city. All that lies to the south of the lake may vie with the best lands of South America. The population is estimated at 100,000. In this province are 300 European regular troops, 100 artillery-men, and 810 militia.—Also, a lake of this province, lying from N. to S., communicating at one extremity with the sea. Its length from the bay to its most southern recess, is, according to Oviedo, 50 leagues, its greatest breadth 30, and its circumference upwards of 150. This lake may have owed its formation to the slow and gradual excavation occasioned by numerous rivers, which, flowing from E., W., and S., here terminate their course. It is easily navigated, and carries vessels of the greatest burden. All the produce and provi-

sions of the interior, intended for consumption or shipping at the town of Maracaibo, are conveyed by the rivers which discharge themselves into this lake. Hurricanes are not unfrequent in this lake, and yet there is always a kind of undulation on the surface of the water, so that, on particular occasions, its waves are sufficiently agitated to bury under them the canoes and small craft. At this time the waters of the sea force themselves into the lake, and give a brackish taste to it as far as Maracaibo; but at all other times it is fresh and fit for drinking as far as the sea. The baths which are used there, and which the intense heat of the country renders indispensable, are attended with very salutary effects. All the different kinds of fish furnished by the rivers of South America abound in this lake. To the N.E. of it, in the most barren part of the borders, and in a place called "Mena," there is an inexhaustible mine of mineral pitch, which, mixed with fuel, is used for graving vessels. The bituminous vapours issuing from this mine are easily inflamed, and in the night luminous corruscations are visible, which resemble lightning, and which are denominated the lanterns of Maracaibo, because they serve for a light-house and compass to the Spaniards and Indians who navigate the lake. The sterility, and also the noxious atmosphere of the borders of the lake, discourage culture and population. The Indians are so unhealthy, that they prefer dwelling on the lake itself to taking up their abodes on its borders. The Spaniards found on this lake several villages, built without order, and without apparent design, but with solidity. Hence they gave them the name of "Venezuela," a diminutive of Venice, which they have not retained, but which has since been applied to the whole province. Four of these villages remain, and the Indians who inhabit them have a church, which is under the care of a curate, who is entrusted with the charge of administering spiritual aid among the aquatic Indians. The great resource and chief employment of these people is the hunting of wild ducks, which they take by thrusting their heads into empty calabashes, closed so that they may see without being seen, and swimming to the place where the ducks are, which they lay hold of by the legs, before they are alarmed, and tying them to their belts, thus bring them to the shore.

The goodness of the soil in the western part has induced some Spaniards, regardless of the insalubrity of the air, to fix their habitations there, in order to raise cocoa and provisions. These settlements, which were very much dispersed, were not able to command sufficient funds for laying the foundation of a village, much less of a city. There is but one chapel, placed nearly in the centre of the scattered habitations, and a curate for performing divine service, and administering the sacrament. The southern extremity of the lake is uncultivated and uninhabited. The northern part is quite as hot as the other parts, but much more healthy.—Also, a town or city which is the capital of the province of the same name, situated on the left bank of the lake to the west, at the distance of about six leagues from the sea, on a sandy soil, and in a hot dry climate, chiefly experienced from March to October; but in July and August the air seems to proceed from a furnace. The only antidote is to bathe in the lake; and endemial disorders are unknown. The thunderstorms and torrents are here terrible; and if they fail, earthquakes certainly follow. Although many houses are built of lime and sand, and with considerable taste, most of them are meanly covered with reed, and there is no water but that which is derived from the lake, which is salubrious, though not pleasant, especially in March and April, when the strong breezes impregnate it with sea-spray. The principal part of the city is on the shore of a small gulf, one league in depth, which

which forms the lake towards the west. The other part is to the north, in the neck of the lake, which at this place is three leagues wide, whence it begins to extend towards the south. The point where the city begins is called "Maracaibo Point;" that where the gulf commences "Point Aricta," situated almost opposite to "Point St. Lucia." According to an enumeration in 1801, there were about 22,000 inhabitants; and they were increased by the Spanish refugees from St. Domingo. With this accession, the population was raised to about 24,000 persons, who are distributed into four classes; the nobility, consisting of about thirty families; white planters, composed of Europeans or Creoles, who apply to agriculture, navigation, commerce, the fisheries, &c. and live comfortably; slaves and freemen, who exercise all kinds of trades, joiners, tailors, shoe-makers, carpenters, masons, and smiths. The slaves do not exceed 5000. The habit of sailing on the lake encourages the spirit of navigation, and many of the natives become seamen. Even in the dry Savannas they contrive to feed numerous herds; and the youth are celebrated for intelligence and ingenuity; but the inhabitants are rather noted for want of probity. The women are fond of the harp, which resounds in the streets in the evening. In their youth they are distinguished by their modesty, and, when married, are faithful affectionate wives and excellent mothers, directing their attention to domestic cares, and the education of their children. Here is only one church, aided by a chapel of ease, and a convent of Franciscans. At Maracaibo they adore a virgin, which bears the surname of "Chiquinquirá," which was the name of a village in the kingdom of Santa Fé, where she made her first appearance. Her passion is to paint herself on dish-cloths, and in the midst of filth. A temple, on the discovery of her in 1586, was dedicated to her; and, as the fabulous tradition reports, a fountain rose under the altar where she was placed. She communicated to its waters miraculous virtues, which have given to her permanent reputation among the Spaniards. The image of this virgin is placed in the chapel of ease of St. Juan de Dios, where she is invoked by all mariners as their imaginary protectress. The foundation of this town was laid, in 1571, by captain Alonso Pacheco, an inhabitant of Truxillo, under the name of New Zamora, now known only under that of Maracaibo. At the entrance into this port is a bar of quick-sand, ten or twelve feet under water, which excludes large vessels, and admits small ones with difficulty, and not without the conduct of a skilful pilot. As soon as the bar is cleared, there is plenty of water and a good harbour, which is defended by three forts. The manufactures and merchandises that are brought hither from places near the lake are put on board Spanish ships that come hither to purchase them. Maracaibo is the seat of a governor, who enjoys the same salary, and exercises the same functions, as the governor of Cumana. This place is very convenient for ship-building: 270 miles E. of Carthagena. N. lat. 10° 30'. W. long. 71° 46'. Depons' Travels in South America.

MARACANA, a town of Brasil, in the government of Para, on a river which runs into the Atlantic; 80 miles N.N.E. of Para. S. lat. 0° 27'. W. long. 49°.

MARACANA, in *Ornithology*, the name of a bird of the parrot-kind, but larger than the common species, and covered all over with blueish-grey feathers. It is very common in the Brasils. See *PSITTACUS Cincereus*.

The natives also call another bird of the parrot-kind by the same name, which is of a fine green on the head, neck, and back, but the crown of the head looks a little blueish; the tail is mixed of red and a blueish-green; the under part being red, as is also the under part of the wings; at the

origin of each wing, it has also a red spot; and on each side of the head a brown one. The noise this bird makes is oe, oe, oe. See *PSITTACUS Severus*.

MARACANDA, in *Ancient Geography*, a very considerable city of Asia, and capital of Sogdiana, which was captured by Alexander the Great, who, after leaving a strong garrison there, burnt and laid waste all the plains. See **SAMARCAND**.

MARACAPA, in *Geography*, a town of South America, and capital of a district of the same name, in the province of Cumana; 42 miles W. of Cumana.

MARACAXAO, in *Ornithology*. See **FRINGILLA Melba**.

MARACAY, in *Geography*, a beautiful new village of South America, in the government of Caraccas, situated in the rich vales of Aragoa, 40 miles S.W. of Caraccas; famous for the culture of chocolate. The industrious inhabitants, mostly Biscayans, have been computed at more than 8000, and the vicinity is crowned with numerous plantations of cotton, indigo, coffee, and grain.

MARACCI, LEWIS, in *Biography*, a learned Italian, was born at Lucca in the year 1612: in his youth he applied himself most diligently, and with great success, to the study of the eastern languages, particularly to the Arabic. His skill in this tongue led to his appointment to the professorship of Arabic in the college of wisdom. He was also selected by pope Innocent XI. as his confessor, which mark of high confidence and honour would have been followed by a cardinal's hat, but the humility of Maracci led him to decline that distinction. He died in the year 1700, at the great age of eighty-eight. He had a considerable share in editing the "Arabic Bible," which was published at Rome in the year 1671, in three volumes folio: he is known also for a work which he printed in Padua but two years before his death, entitled "Alcorani Textus Univerfus Arabicè et Latinè," in two vols. folio. This version is accompanied with notes, a refutation of the Mahometan doctrines, and a life of the Pseudo-Prophet. The work, though not wholly free from errors, is highly applauded by the learned. Maracci was author also of "The Life of Father Leonardi," the founder of the congregation to which he belonged, and of numerous other pieces.

MARACU, in *Geography*, a river of Brasil, which runs into the Atlantic, S. lat. 2° 40'. W. long. 45° 31'.

MARADECANUM, a town of Hindooostan, in the circuit of Cicacole; 15 miles N.E. of Tickely.

MARÆNA, in *Ichthyology*. See **SALMO Marana**.

MARAGA, MARAGHA, or Mirga, in *Geography*, a town of Persia, in the province of Adirbeitzan; 30 miles S. of Tabris. N. lat. 37° 20'. E. long. 46° 22'.—Also, a town of Egypt, on the left bank of the Nile, the environs of which are said to yield the best wheat in Egypt; 6 miles S. of Taha.

MARAGAL, a town of Persia, in Adirbeitzan; 42 miles S. of Tabris.

MARAGHA, a town of Syria, in the Desert, where an observatory was erected by order of Hulaku, one of the descendants of Jenghiz Khan, and furnished with instruments for astronomical observation; 75 miles E.S.E. of Aleppo.

MARAGNON. See **MARANON**.

MARAH, or MARRA, a town of Syria, in which the Roman Catholics have a church, and the Greeks a church and convent; 15 miles N.E. of Damascus.

MARAHBUTS, or MARABOUTS, derived from a word which signifies a monk, or a man engaged to the performance of his vow, denote Mahometan priests, who are dispersed through various parts of Africa. Those of the Mandingo nation

nation apply themselves, besides religious matters, to the study of physic, as far as it depends on mere experience, without entering into the investigation of the causes of diseases. They are also often called upon by the kings and chiefs to give their opinion in cases of law and equity. Most of them are well versed in the Arabic language of the Mauritanic dialect, and they are the only people of letters among the blacks; for none of the black nations about Senegal and Gambia have even an alphabet, much less any writings in their own languages. The selling of charms is said to constitute the greatest part of their revenue; and the more reputation any one of them has acquired, the dearer is it sold. These charms usually consist in nothing but a few lines taken from the Koran, written on a little piece of paper, which, after being nicely sewed up in leather or cloth, are worn by the purchasers about their necks. They are designed to protect and defend them in danger; but as one charm has only the power of preserving them from one kind of danger, they are obliged to have many of them; so that many of the blacks are covered with them in different parts of the body; and they have such a strong faith in them, that when they are surprised in the night-time by an enemy, they will not take up arms for their own defence, though in the most imminent danger, till they have dressed themselves with these charms, and then they will meet him undauntedly. This faith in charms, however, is a corruption of the Mahometan religion; and the Moors, who live on the north side of the river Senegal, observing it in its purity, make no use of them.

The Marahbuts of the black nations, as well as those of the Moors, are also the principal merchants, and the most opulent people among them, and the gum trade on the river Senegal is chiefly carried on by those of the Moors. The Marahbuts are also the only people who can travel with any safety into distant kingdoms, which no layman can well do without running the risk of being made a slave. Their religious profession protects them every where; they are even respected among those nations who are not Mahometans; and they are considered by them as a godly and virtuous people, and men of wisdom. They make profelytes every where to the Mahometan religion, and are industrious in spreading it all over Africa. Some Marahbuts of the Foolah nation who visit Senegal, are pretty well versed in the Old Testament, and are partly acquainted with the institutes of the new one. The Marahbuts reason very well on such subjects as they are acquainted with, but their manner, like that of the eastern nations, is that of adducing parables or similes in their arguments, which do not always bear the strictest resemblance to the case in hand; though they are very persuasive with such people as are not capable of investigating the points in which they differ from the case in question. Their conversation is instructive and pleasing. The Marahbuts of the Moors are more learned and ingenious in every respect than those of the black nations. Phil. Trans. vol. lxxiii. p. 90.

MARAI, a town of Hindoostan; 45 miles S.W. of Allahabad.

MARAJO, an island between the mouths of the Amazons and Para rivers, resembling in its form an oval and triangle; about 160 miles in its greatest length, and 120 in its greatest breadth.

MARAJON, a town on the east coast of the island of Marajo; 24 miles N.W. of Para.

MARSAH, a town of Tunis, near the sea, with the remains of a small harbour.

MARAKUNDA, a town of Africa, in the kingdom of Badelu.

MARALDI, JAMES PHILIP, in *Biography*, a learned mathematician and astronomer, was born at Perinaldo, in the county of Nice, in the year 1665. It is not known where he was educated, but at the age of twenty-two we find him at Paris, pursuing his maturer studies under his uncle, the celebrated Cassini, to whom he implicitly resigned the direction of his pursuits. When Cassini found that the young man's advancement in science, his extraordinary diligence, and above all his accuracy, had qualified him to become an useful assistant in his astronomical labours, he, by the leave of the Royal Academy of Sciences, associated him with himself in making observations on the celestial bodies. He soon opened the way to celebrity, by important discoveries with regard to the planets, particularly with respect to Jupiter: he found likewise that the parallax of the planet Mars was less by one second, than had been determined by Cassini in 1672. He spent the whole of the year 1674 in observations on the planet Saturn, and shewed how the disappearance of the ring, at that particular period, confirmed the theory of Huygens. He bestowed incredible industry in perfecting the tables of Jupiter's satellites, and found that the eclipses of these bodies were of different durations, even when the distance of their nodes was the same. He applied himself to the constructing a catalogue of the fixed stars, and by his long and accurate attention to this object, became so well acquainted with these bodies, that on being shewn any one of them, however small, he could immediately tell to what constellation it belonged, and its precise place in the constellation. Maraldi would sometimes relax in his astronomical labours, and apply steadily to objects of natural history, on which science he drew up a number of interesting papers, which were inserted in the different volumes of the memoirs of the Academy of Sciences, of which distinguished society he was a member. In the year 1700, he was employed by Cassini in prolonging the French meridian to the northern extremity of France, and had a very considerable share in that important undertaking. When his business was finished, he paid a visit to Italy, where the astronomers gladly availed themselves of his advice and assistance in making their observations. At Rome, on the invitation of pope Clement XI., he assisted at the assemblies of the congregation then sitting in that city, for the purpose of reforming the calendar. He also took a part in constructing the great meridian line at the baths of Dioclesian. While at Rome he had a fine opportunity of observing an eclipse of the fourth satellite of Jupiter, from which he was led to the conclusion, that its inclination is three minutes less than that fixed by Cassini. He returned to France in 1703, with a rich treasure of subjects in natural history, chiefly collected at Verona, which he presented to the Academy of Sciences. In 1718 he was employed, with three other academicians, in prolonging the French meridian to the southern extremity of that kingdom. Amidst his various labours the greatest part of his time was occupied within the walls of the observatory of Paris, where he was incessantly employed in astronomical pursuits, and in completing his catalogue. This last great work he did not live to finish; he died in December 1729, in the sixty-fifth year of his age. He is characterized as a man of great seriousness, integrity, and purity of morals, and as possessing an interesting simplicity of manners. He published nothing but papers in the transactions of the academy: these, however, are very numerous and very valuable, and are to be found in almost every volume that was printed between the years 1698 and 1730. Moreri.

MARAMBAYA, in *Geography*, a small island near the coast of Brazil. S. lat. 23° 10'.

MARAMER, a town of Morocco, near Cape Cantin, encompassed with old walls, but not strong either by nature or art; 9 miles from Saffi.

MARANA, JOHN PAUL, in *Biography*, was born of a noble family at or near Genoa in the year 1642. He received an education adapted to the sphere of life in which he moved, and being led to think and feel upon political subjects, he was, at the age of twenty-seven, involved in the conspiracy of Raphael della Torre to deliver Genoa to the duke of Savoy. On this account he was thrown into prison, where he remained four years. On his liberation he employed himself in writing an account of this conspiracy, and of the war between the republic and the duke of Savoy, and took a journey to Spain for the purpose of collecting documents. When the work was finished, it was seized by the spies of government, and examined, nor could he get it returned for publication. In 1681 he abandoned his country and went to France, where he recomposed his work, and published it in the year 1682, under the title of "La congiura da Raffaello delle Torre, con le mosse della Savoia contra la Republica di Genova." Marana is chiefly known as an author by the "Turkish Spy," written in the French language, which has given birth to several imitations, on the same model, though the original is not much sought after. He lived at Paris in a state of decent mediocrity till the year 1689, when he returned to Italy, where he died in about two years. Moreri.

MARANA, in *Botany*, a name by which some authors have called the stramonium, or thorn-apple, a plant kept in some gardens.

MARAND, in *Geography*, a town of Persia, in the province of Adirbeitzan; 42 miles N. of Tauris.

MARANHAO, or **MARANNON**, a jurisdiction of South America, in Brazil, belonging to the Portuguese, who first settled here in 1599, upwards of 60 years after the discovery. Its name is derived from an island at the mouth of three rivers, about 42 miles in circumference, which is fertile and well inhabited. The French seized on the island in 1612, and built a town called "St. Luis de Maranhao," but the Portuguese recovered it out of their possession. It is now very strong, having a castle built on a rock towards the sea, which commands a very convenient harbour.

It is the see of a bishop, under the archbishopric of St. Salvador de la Bava. The island is difficult of access, on account of the rapidity of the three rivers by which it is formed, so that it can be visited only at particular seasons, and with proper winds. There are two other less considerable towns. The natives have about 27 hamlets, consisting each of four large huts, which form a square in the middle, from 300 to 500 paces in length, and about twenty or thirty feet in depth; all these are built of large timber, and covered from top to bottom with leaves, so that each may contain from two to three hundred inhabitants. The air is serene, seldom incommoded with storms, excessive drought, or moisture, except during the periodical rains from February to June. The soil is rich, and produces every thing in perfection, without labour or manure. The inhabitants go naked, but paint their bodies and faces of various colours, and cover their hands and arms with a variety of feathers: the children, though born white, acquire an olive colour by being anointed with oils. They are strong and healthy, live to a great age, and are seldom afflicted with diseases. Their only weapons are bows and arrows, in the use of which they are dextrous; but they are fierce and cruel, especially to their prisoners. The capital, St. Filipe, or St. Luis de Maranhao, is situated in S. lat. $2^{\circ} 30'$. W. long. $45^{\circ} 30'$.

MARANO, a town of Italy, in Friuli, on the coast of

the Adriatic; containing about 1000 inhabitants, with a garrison; 18 miles S. of Udina. N. lat. $45^{\circ} 50'$. E. long. $13^{\circ} 50'$.

MARANO, or *Mariano*, a town of Italy, in the Veronese; 8 miles N.N.W. of Verona.—**Alfo**, a town of Naples, in Lavora; 6 miles N.W. of Naples.

MARANON, or **MARAGNON**, called also the river of the *Amazons* (see **AMAZON**), is celebrated as the most distinguished river not only in South America, but in the whole world. Of this river we have already given some account under the article **AMAZON**; but it deserves, on account of its magnitude and length, as well as the fertility and commerce that are diffused along its shores, a more particular and ample notice. Condamine, whose account of this river we have cursorily mentioned, computed its navigation at 1000 maritime leagues, or 3000 miles; to which recent discoveries enable us to add at least 4 or 500 leagues: so that if the countries, through which it pursues its course, were possessed by industrious and populous nations, a ship of 4 or 500 tons might ascend this wonderful river to the extent of 4500 miles of navigation. As the course of the Maranon, for more than one-third of its progress, is from north to south, it considerably exceeds the whole breadth of South America; but estimated in a line nearly direct, the length on a map will be found to be about 2500 geographical miles. If we thus estimate the Kian of China, it will be found to reach 2000 miles, and the Ob of Siberia 1900. The Missouri of North America may probably be estimated at 2000 miles. But the pre-eminence of the Maranon has been very much increased by recent discoveries. This prodigious river, this torrent-sea, as it has been called, is not only superior in the length, but in the breadth and depth of its majestic course; and receives on all sides, as tributaries, rivers of such power, that any one would enrich the deserts of Africa, and might spread fertility, trade, and civilization, throughout a wide empire. Where the Beni joins the Maranon, it is half a league in breadth, (the Spanish league being four British miles;) the Tunguragua or false Maranon from the west, the Llavari or Madera from the south, and the Negro from the north, are all rivers of this surprising description. In short, through more than one-half of the great continent of South America, almost every advantage of a maritime shore might be diffused by the Maranon, and its confluent streams. We shall here avail ourselves of the abstract given by Mr. Pinkerton, of the principal discoveries that have recently been made, with regard to the source and tributary rivers of the Maranon. Near its source this river is called the Apurimac, which rises to the south of the mineral mountains of Cailloma, perhaps in the lake of Vilque, as laid down by La Cruz, S. lat. $16^{\circ} 10'$; but probably still more to the south, perhaps even 17° ; for after being joined by the Monigote or Panguana, in Cailloma, it is so deep, when it enters the province of Canes and Canches, that a bridge is already necessary. This bridge is probably that mentioned by Alcedo, on the high-road between Lima and Cuzco, supported by ropes, and eighty "varas" in length, being almost due west of Cuzco, and which passes the real Apurimac, according to La Cruz, while the Vilcamayo is on the east of Cuzco. After running two leagues below this bridge, it bursts through the chain of the Andes amidst precipices of incredible height, and which supply numerous streams. The chief rivers which join the Maranon are as follow: the river of Pampas or Charcas from the west, at $13^{\circ} 10'$; the Vilcamayo, a great river, nearly equal to the Apurimac or Maranon, at $12^{\circ} 15'$: this river, like the others, has several names, according to the provinces through which it passes, such as Quillabamba,

MARANON.

Quillabamba, Urubamba, &c. The Mantaro, or river of Jauja, so called from the province it pervades, but by La Cruz erroneously styled the ancient Maranon, joins the Maranon at $12^{\circ} 6'$, and seems to propel the chief river towards the north-east, the course having previously been towards the north-west. The great river Paucartambo, called by La Cruz Ynambari, joins the Maranon at $10^{\circ} 45'$; the Perene, which rises about two leagues from Tarma, runs through that town, and receives many streams from the heights of Bombom and Pasco, having joined it on the opposite side or west, at $11^{\circ} 13'$. From the confluence of the Perene to that with the beautiful river Pachitea, at $8^{\circ} 26'$, that is an interval of $2^{\circ} 52'$, or 172 geographical miles, though by numerous windings increased probably to 500, the Maranon receives no less than 40 copious rivers; but more particularly two of prodigious power, the Paucartambo already mentioned, and the Beni, the most remote springs of which lie east of the province of Sicasica, in about 10° of latitude. This river runs from south to north, with some inflections, receiving various rivers from the mountainous territory which it intersects; among the most remarkable of which is the Coroyco, issuing from the province of La Paz, and entering it on the west. The Beni, pursuing its course in 13° of latitude, throws off a branch, in an eastern direction, which enters a considerable lake, named Rogagado, that extends upwards of 10 leagues E.W., and of 5 N.S. From the eastern side of this lake rises an arm, which runs to the Mamori; and three others are thrown off in a northern direction, viz. the Yutay, the Tesi, and the Coari, which pursuing a north-east course, empty themselves into the Maranon. The Beni, having supplied this arm, flows to its incorporation with the Apurimac, which it enters with an aperture of half a league, and by the name of Para. Three leagues beneath the junction of the Paucartambo, the Maranon is joined by a river, about two British miles, or half a Spanish league in breadth, of such force that the course of the Maranon is changed for a certain distance, and bent towards the chain of the Andes. This river, however, wide and powerful as it is, is only a branch of the grand river Beni, already mentioned. Indeed it has been queried whether the Beni or the Apurimac be the principal stream forming the Maranon. The source of the Beni, near Sicasica, is about $2^{\circ} 30'$ farther to the south than that of the Apurimac; but as its course is far more direct, the actual length of the navigation bears no comparison with that of the Maranon, which at this junction acquires the name of the Grand Para or Pare. The navigation of the Beni might conduct the adventurer to the mines of Potosi, and that of the Apurimac to Cuzco and Lima. At $8^{\circ} 26'$, the Pachitea joins the Maranon. The Pachitea is esteemed the most beautiful of all these tributary streams: it rises in $10^{\circ} 46'$, first running east, then north, and in the early part of its progress is called the Pozuzo, especially at its confluence with the Mayro, where it forms a noted haven, whence there is an open navigation to the Maranon. The next remarkable stream that joins the Pachitea is the Piachiz. The course of the Maranon here varies from due north to north-east; so that the map of La Cruz must be erroneous in the great westerly inflection of its course, thereby approaching the Gualaga too nearly by one-half. The Aguaytra also joins the Maranon from the west, at $7^{\circ} 35'$; the Manoa or Cuxniabatay, at 7° ; the Saraiacu, at $6^{\circ} 45'$; the Tapichi or Canopocati, opposite to San Regis, at 5° , which last river seems also to communicate with the Tunguragua. This Tunguragua, Lauricocha, or Jesuitic Maranon, falls into the Maranon at $4^{\circ} 55'$, where the latter is divided into three branches, the chief of

which is not less than 55 fathoms in depth. The course of the Maranon now turns to the east. The true Maranon, or Ucaial, as it is also called in part of its course, is the most important of all the streams which descend from the grand chain of the Andes. In 1794 it was explored by Father Girval, who navigated it from its junction with the false Maranon to its confluence with the Pachitea, and found it of a serene current, and abounding with fish, while animals of chase swarm on the shores. The savage tribes on this superb river are generally pacific, and seem to speak dialects of the same language. From its junction with the river Beni to that with the false Maranon it is navigable for large vessels more than 400 leagues; and in the course of 300 leagues presents 132 islands. The true Maranon, or Ucaial, is navigable at all seasons. The first Portuguese station that occurs is Sapatinga, and the next San Pablo. Loreto, a Spanish fortress, stands at the distance of 12 leagues from Sapatinga; from which latter Pevas, a Spanish village, is 74 leagues, Napo 104, Iquitos 132, Omasias 154, the junction of the Ucaial 164, the village of San Regis 184, that of Urarinas 224, and the mouth of the Gualaga 234. See GUALAGA.

The banks of this large river are generally crowned with vast forests of lofty trees, among which are many of a rare and medicinal nature. Serpents of prodigious size are found in the marshes, and alligators are also common. It seems certain, from the disquisition of Condamine, that some female warriors still exist toward the north of this great river. Near its mouth the Bore rises from 12 to 15 feet in height; and the noise of this irruption is heard at the distance of two leagues. This effect, called "pororoqa," is chiefly observable towards the cape del Norte, on the mouth of the Arowary. See BORE.

The successive voyages of Father Girval are rendered interesting, not merely by his having explored the Ucaial or genuine Maranon, but by the account he has given of the different tribes of Indians who inhabit the adjacent territory. Embarking on the lake of the great Cocama, he proceeded to Omasias, at the confluence of the Maranon and Tunguragua, commonly called St. Joachin, as distinguished from St. Pablo, or St. Paul de Omasias, one of the first Portuguese settlements at the linear distance of about 3° , or 180 geographical miles to the E. Having two canoes with 14 Omaguan Indians, robust and dextrous rowers, he soon passed from the Tunguragua into the Maranon, which he ascended with resolute and laudable perseverance, though he sometimes met with little fleets of canoes filled with Indians of unknown tribes, whom he foothered and escaped by his prudence. The "Conibos" will employ a whole year to hollow out a canoe from one tree, 16 or 20 yards in length, and from five to seven quarters broad, which they accomplish by means of sharp stones and fire. The poop is square, and the prow drawn to a pyramidal point. Among their slaves were some of the Mayoruna tribe, who dwell towards the sources of the river Tapichi, and are called Barbudos, because their beards are as strong and abundant as those of the Spaniards; but they are believed to be descended from Spanish soldiers, scattered in these forests in consequence of a former expedition. After 14 days of navigation, there appeared on the W. a chain of mountains, running S.E. and N.W. Two days after they arrived at the little settlement of Saraiacu, among the "Panos," and soon after reached the habitation of Anna Rosa, an Italian lady, educated at Lima, who greatly lamented the tragical death of the missionaries in 1767, committed by the "Chipeos," who had been severely chastised by her nation. Continuing the ascent he reached the river Manoa, also called by the Indi-

ans Judiabalay, on account of the rapidity of the stream, which nevertheless he ascended with a view of discovering a nearer passage from the Gualaga to the Maranon than the circuit by the Tunguragua. The passage by land was found difficult, on account of thick woods and precipices; and discovering a large river, which was the winding Manoa, our traveller descended the Maranon, and arrived at the missions of the Maynas, and soon after at Cumbaza, after an absence of four months. This first voyage seemed to obliterate the idea, which he had entertained, of the cruelty of the nations on the Maranon. The Indians in general were found to be tall and robust, and the "Conibos" could vie with the Europeans in fairness, if they did not discolour themselves, and suffer moreover from the stings of the mosquitoes. They bind their children with bandages of flax, that they may grow straight: the forehead is also flattened in infancy, by boards fastened before and behind, as in their opinion a wife head should resemble a full moon: but by this practice, it is said, they are almost utterly deprived of memory. The girls are wholly naked, while the married women wear a slight cincture; but among many other tribes complete nakedness is universal. They are painted and tattooed; they do not marry within certain degrees; and the caziques alone use polygamy; but the men and women are free to quit each other. They seem to believe in one god, of a human form, who retired to heaven after making the earth; but they do not venture to offer their humble adorations except during earthquakes, which they believe to proceed from the footsteps of their god who visits the earth, in order to judge by their voices how many men exist. Hence, on occasion of the slightest earthquake they run from their hovels, caper, and stamp on the ground, crying out, "here we are, here we are." They also believe in an evil spirit, of whom the most sagacious, for the sake of emolument, have declared themselves the priests, and regulate in his name amours, intrigues, health and sickness, and the little campaigns of war. They have also many charms and amulets; and yet their skill in medical herbs is far from being contemptible. They also believe in another life, but imagine that thunders are the battles of that distant world, and that the milky way is a fine forest for their diversion. Some believe in transmigration, and suppose that the souls of their chiefs and nobles animate tigers and monkeys. The dead are disinterred after a certain period, and the bones washed and preserved, but some tribes eat the flesh, that nothing may be lost. Besides the chase and fishing, they cultivate a few herbs, particularly the "yuca," with which they make the "mazato," their only drink and consolation. The water is generally bad, owing to the heat and the numerous marshes which taint the rivers. In the cultivation of the "yuca," they cut down the trees with axes of stone; but they have also axes of copper, the first metal used by savages, being often found native and easily beaten into form, while iron is obdurate and requires the skill of a more advanced society. The ground is slightly moved with a wooden spade, and the "yuca" being interred the labour is finished. They also gather cotton, which serves for their little cinctures. Their darts and arrows are often tinged with active poison, drawn from noxious plants. Their confidence in its power is such, that they will excite the fury and await the attack of the strongest and fiercest jaguar. They laugh when he prepares to spring: the arrow flies, and he is dead. But they never employ poisoned weapons in their conflicts, not so much from liberality of sentiment, as from the fear of a retort. Large fish are killed with arrows aimed at their heads; the small are taken in snares, or with hooks of bone. From the age of five years boys and girls manage the canoes.

VOL. XXII.

Their ruling passion is war, and it is the business of the whole tribe, presided by the cazique or intended general. The tobacco tubes are lighted; the jars of "mazato" pass round; and as soon as drunkenness begins, this important subject becomes the matter of deliberation: the first and most solemn question being, "with what nation shall we go to war?" And the next is, "what shall be the cause of quarrel?" The causes are generally some petty robbery or offence; and the weakest tribe is generally selected as the most convenient enemy. When the expedition is resolved upon, the "moans," or priests of the evil spirit, take charge of their chiefs, and treat them with such abstinence and artificial horrors, that at the end of some days they come forth rather dead than alive. These savages impute all success in war to the evil spirit, and carefully conceal from their deity their proceedings on such an occasion. Hence the "moans" are held responsible for the result of the expedition; and if it be adverse they receive a thousand maledictions, and are beaten almost to death, because their prayers to the evil spirit had not been acceptable. As their petty warfares are incessant, their villages, or large houses, are prepared for defence; being constructed in the form of a crescent, with the convex part towards the wood, and with one door towards some hill and another to a plain. When the enemy attack at one door a party opposes; while the others turn the wings of the house, and attack the foe on the plains.

Father Girval, in his second voyage 1791, entered the mouth of the Ucaial, or true Maranon, and though unaccompanied by any soldier, or white person, he was received by the savages with great cordiality, though he was afraid of encountering the "Casibos" on the eastern shore, who are reputed the most ferocious tribe in those regions. But the chief navigators of this part of the Maranon are the "Conibos," who are more humane; and the sound of their rude flutes or cornets is the signal of peace and hospitality. Canoes of the "Panos" afterwards appeared: and the Father arrived at Saraiaicu with a bark and 60 canoes of friendly savages. The cazica, Anna Rofa, conducted the procession to a little convent which she had founded, and the Indians obeyed her orders with great punctuality. A tribe called the "Piro" inhabit the borders of Maranon, in the latitude of Torma, being about 20 days navigation from Saraiaicu or the Manoa. He found abundance of cinnamon trees, and began to instruct the natives in its cultivation, hoping that this precious spice would soon become an essential article of commerce. This settlement was thought of importance, as it prevented the Portuguese ships from pursuing their excursions on the Maranon; and with the fort on the Mayro, inclosed the "Pampas del Sacramento" on both sides, so as to render it a decided Spanish province.

The "Panos" and "Conibos," and even the "Chipeos," who had murdered the first missionaries, began, it is said, to shew some disposition for embracing the faith. Some "Piros" were exported from the vicinity of the Mantaro, and the frontiers of Guanta and Jauja, passing in their canoes on the Maranon; but the "Casibos" near the Mayro, and on the banks of the delightful Pachitea, a ferocious race, were scarcely expected to become amicable; having no intercourse with any other nation, and never leaving their own country, as they have no utensils for making canoes. They surprise and kill any strangers whom they find within their boundaries; and having cooked them with great care, eat them with corresponding comfort, so that a traveller rarely returns to publish any account of foreign parts. These savages form the only obstacles to impede the navigation from Manoa to Mayro; but a few regular troops would easily extirpate these irreclaimable tigers. Of these mission-

aries it is justice to add, that occupied in teaching these savages the arts of life, and of innocent sustenance, whatever a Protestant may think of their religion, he cannot withhold the applause due to their fortitude and beneficence. Pinkerton's Geog. vol. iii.

MARANON, *False* or *Jesuits'*, called by the natives *Tunguragua*, and also *Lauricocha*, a river of South America, which rises from the lake of Lauricocha, about eight miles to the N. of Pasco, and after passing the Pongo, becomes navigable till it falls into the Ucaial or true Maranon. We may here state, on the authority of father Girval, the reasons alleged by those who assign the supremacy to the Ucaial. In the first place, its sources are far more distant than those of the Tunguragua, or pretended Maranon of father Fritz: secondly, the Beni, Paucartambo, and the Apurimac, are navigable up to a latitude where the false Maranon has no existence: thirdly, because the Ucaial, far from being inferior in the quantity of water, is on the contrary broader, and forces the false Maranon out of its course: fourthly, because all the ancient historians of the kingdom have acknowledged the Apurimac as the genuine Maranon: fifthly, because, till the year 1687, the very name of Ucaial was unknown, that river being called Apoparu, *i. e.* the great Paro, which is the name also given by the natives to the Maranon, or the river of Amazons, after it is joined by the pretended Ucaial. In the year above-mentioned, a law-suit arose between the Franciscans of Lima and the Jesuits of Quito, for the village and missions of San Miguel de los Conibos. The Royal Audience demanded maps in order to determine with greater certainty; upon which father Fritz drew the map, which was afterwards engraved at Quito in 1707, and in which the Tunguragua is styled the Maranon, and the Paro is ridiculously called "Ucayali," a word, which merely signifies a *confluence*, and specially applied by the tribe of the Maynas to that of the Paro and Tunguragua; whence originated the error of father Fritz; while father Acuna asserted, with equal boldness, that the Napo was the Maranon! The great credit of the Jesuits led people blindly to follow the nomenclature of father Fritz. Upon the whole it is sufficiently manifest, that the great river Maranon is that denominated the Ucaial by a mere manœuvre of the Jesuits, in opposition to the most palpable facts and the ancient history, traditions, and present accounts of the natives; and that the river Ucaial or Apurimac ought to retain to its very source the real and just appellation of the Maranon: while to the false Maranon, in fact a tributary stream, and recent appellation confessedly erroneous, whether arising from artifice or mistake, the ancient name of Tunguragua ought to be restored. This new Maranon, Tunguragua, or Lauricocha, was navigated by Condamine from near the town of Jaen, where it begins to be navigable; thence passing N. E. it arrives at the exterior ridge of the Andes, which it cleaves at a pass called the Pongo, a word which in the Peruvian language signifies a gate. This sublime scene displays the Lauricocha confined between two parallel walls of an almost perpendicular rock. From a breadth of 250 fathoms the river is here contracted to 25; but the rapidity is not extreme, and a raft passes the two leagues in about an hour. Pinkerton's Geog. vol. iii.

MARANS, a town of France, in the department of the Lower Charente, and chief place of a canton, in the district of Rochelle; situated in the midst of salt marshes, on the Sevre, about six miles from its mouth. The trade of the inhabitants is considerable in salt, malt, corn, and meal; 12 miles N.N.W. of La Rochelle. N. lat. 46° 18'. E. long. 0° 54'.

MARANT, or AMARANT, a town of Persia, in the province of Adirbeitzan, containing 2500 houses, each of which has a garden, situated near a river, and watered by canals. Cochineal is found in the neighbourhood. Tradition reports, that Noah was buried here; 50 miles N. of Tabris.

MARANTA, in *Botany*, was so named by Plumier, in commemoration of Bartholomew Maranta, a native of Venusia, who died in 1554. He was one of the chief Italian botanists of his time, and examined the native plants of his country, while he cultivated exotics in his garden, and commented on Dioscorides with great diligence and sagacity. He wrote also on the Theriaca and Mithridate, in Italian. Plum. Nov. Gen. 16. t. 36. Linn. Gen. 3. Schreb. 4. Willd. Sp. Pl. v. 1. 13. Mart. Mil. Dict. v. 3. Roscoe Tr. of Linn. Soc. v. 8. 339. t. 20. f. 2. Ait. Hort. Kew. ed. 2. v. 1. 2. Juss. 63. Lamarck Illustr. t. 1.—Class and order, *Monandria Monogynia*. Nat. Ord. *Scitamineæ*, Linn. *Cannæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, of three small, equal, lanceolate, permanent leaves. *Cor.* of one petal, irregular. Tube longer than the calyx, compressed, oblique, inflexed. Limb double, unequal, the three outermost segments smallest, equal, alternate, oblong, one of them inferior, two superior; innermost in two roundish lobes, very large, deflexed, constituting the lip, sometimes undivided. *Stam.* Filament one, opposite to the lip, dilated, resembling a segment of the corolla; another linear, attached to one edge of the filament, of two cells. *Pist.* Germen inferior, roundish; style dilated, petal-like, the length of the stamen, to which it is united below; stigma obsolete triangular, inflexed. *Peric.* Drupa roundish, somewhat triangular, dry and leathery, of one cell. *Seed.* Nut solitary, oblong, rugose, hard, of three cells, two of which are generally abortive.

Eff. Ch. Calyx of three leaves. Corolla of one petal, in five segments. Anther simple, on the edge of the filament. Style petal-like. Stigma somewhat triangular. Nut solitary, of three cells.

Obf. This genus belongs to that section of the Linnæan *Scitamineæ*, which is characterized by a simple anther of two cells, not a double one whose cells are distant from each other and embrace the thread-shaped style. The term *Cannæ* is restricted by Mr. Roscoe and Mr. Brown to the section in question. Jussieu extends it to the whole of the *Scitamineæ*.

1. *M. arundinacea*. Indian Arrow-root. Linn. Sp. Pl. 2. Redout. Liliac. t. 57. Willd. n. 1. (*M. arundinacea*, *cannacori folio*; Mart. Cent. 39. t. 39. *Canna indica*, *radice albâ alexipharmacâ*; Sloane Jam. v. 1. 253. t. 149. f. 2.)—Stem branched, herbaceous, annual. Leaves ovato-lanceolate, somewhat hairy. Flowers panicled. Fruit nearly globose.—Native of South America, and perhaps of some of the West India islands. It is now cultivated in many of them, the juice of the root being reputed a remedy for wounds inflicted with poisoned arrows, as well as against the stings of venomous insects. If the powder sold in the shops of London be really prepared from this root, which we have no reason to disbelieve, its mucilaginous quality may readily account for the above-mentioned virtues. The potatoe might prove efficacious in the same way. This *Maranta* is said to have been sent to England, either by means of seeds or roots, by Houttoun, before the year 1732. It is cultivated in the stove, flowering in July and August, but is not ornamental enough to be very popular. The root is perennial, somewhat creeping, knotty or tuberous, with many long white fibres. *Stems* several, erect, herbaceous, a yard

yard high, branched, slender, finely hairy, leafy, rather knotty at the joints, dying down to the root every year. *Leaves* alternate, solitary at each joint, with long, sheathing, ribbed, somewhat hairy footstalks; ovate at their base; lanceolate or tapering towards the end; entire, with one rib and numerous transverse parallel veins; paler and somewhat hairy beneath; each about four inches long. When dry they are involute, marked, on the upper side, with fine streaks parallel to the veins, and on the under, with equally fine transverse corrugations, contrary thereto. *Panicles* terminal, long, lax, and spreading, their stalks slender, tumid and hairy at the base, furnished at every ramification with a solitary, long, linear, narrow, ribbed, at first sheathing, *bractea*. *Germen* somewhat hairy. *Calyx* green, smooth. *Corolla* white; its tube about half as long again as the calyx; lip above half the length of the tube, its segments separate to the base, obovate, slightly emarginate. *Fruit* nearly globular and equal, with three obsolete angles, the size of a small currant, the surface corrugated when dry.

2. *M. gibba*. Gibbous-fruited Arrow-root.—Stem branched, shrubby, perennial. *Leaves* ovate, taper-pointed, smooth. *Flowers* panicled. *Germen* silky. *Fruit* gibbous at one side.—Native of Barbadoes, from whence it was sent by the earl of Seaforth, when governor of that island, to the botanic garden at Liverpool. The curator, Mr. Shepherd, favoured us with a fresh specimen, flowering in November, 1808. The latter observes, that the *stem* does not die down in winter. In general appearance this much resembles the foregoing, but the *leaves* are quite smooth, except the knot which combines them with their footstalks, which is, as in the former, very hairy upwards. The *flowers* are smaller; their *germen* beautifully silky, with dense silvery hairs, though the *stalk* below, and *calyx* above, are perfectly smooth and naked. All the *fruits* we have seen, five in number, were so gibbous at one side as to be semi-globose. They lose their pubescence in ripening. A plant was raised from the seed of this species, ripened at Liverpool.

3. *M. sylvatica*. Wood Arrow-root. Roscoe Tr. of Linn. Soc. v. 8. 340.—Stem much branched, shrubby, perennial. *Leaves* ovate, acute, smooth, with a hairy central line above. *Flowers* panicled. *Germen* hairy upward.—This was likewise sent from Barbadoes to the Liverpool garden, by lord Seaforth. It flowers less freely than the last, and had not in 1808 shewn any sign of forming seed. The *stem* is hard and knotty, somewhat in the style of a bamboo. *Leaves* numerous, about two inches long, ovate, scarcely taper-pointed, smooth, except a constant hairy line, close to each side of the nerve, above. They are striated above and below, in this and the last, exactly as in *M. arundinacea*. The knot between the leaf and the footstalk is thick, short, hairy upwards. *Flowers* few and small. *Calyx-leaves* broader, and not half so long as in either of those before mentioned, being quite elliptical. *Corolla* not twice the length of the calyx. *Germen* clothed, in its upper part only, with a few long white hairs, which appear soon to fall off.

4. *M. Tonchat*. East Indian Arrow-root. Willd. n. 2. (*Donax Arundastrum*; *Leureir. Cochinch. 11. Arundastrum, vel Tonchat feytam*; *Rumph. Amboin. v. 4. 22. t. 7.*)—Stem branched, shrubby, perennial. *Leaves* elliptic-ovate, pointed, smooth. *Flowers* panicled. *Germen* silky. *Fruit* globose. *Corolla* five times the length of the calyx.—Native of woods, plains, and vallies in the East Indies, from whence it was brought us by lord viscount Valentia. Rumphius says it is more plentiful in Ceram and Celebes, than in Amboyna. Loureiro gathered it in the

woods of Cochinchina. (See *Donax*.) The *stem* is eight feet high, shrubby, hard, round, smooth, and solid; simple and naked in the lower part; branched and leafy above. *Leaves* broad-ovate, with a small point, scarcely three inches long in our dried specimen; Rumphius describes them as a span in length, and the breadth of five or six fingers. They are smooth, with many lateral veins, but not striated lengthwise or transversely as in the three foregoing. The knot at their base is cylindrical but short, somewhat hairy, sometimes curved. *Panicle* erect when in flower, drooping in fruit. *Bracteas* large and long. *Flowers* white, considerably larger than any of the former. *Calyx-leaves* tapering from a broad base to the point, strongly ribbed, a quarter of an inch long. Tube of the *corolla* scarcely exceeding the calyx; segments of the outer limb above an inch long, linear; lip still longer, stalked, with broad dilated rounded lobes, whose number and position we cannot, from the dried specimen, ascertain. The *germen* is short and broad; very densely clothed with white silky down. *Fruit*, according to Rumphius and Loureiro, nearly globose, exactly agreeing with our generic description. This species is, as Ventenat has observed under *M. arundinacea*, very different from *M. Tonchat* of Aublet, which may be merely a variety of the first species; but this we have no means of determining.

5. *M. lutea*. Yellowish Arrow-root. Jacq. Collect. v. 4. 117. Ic. Rar. t. 201. Roscoe Tr. of Linn. Soc. v. 8. 339.—Stem branched, shrubby, perennial. *Leaves* ovate. Branches of the panicle somewhat spiked. *Bracteas* ovate, imbricated, coloured.—Native of moist woods in the Caraccas. It flowered with Jacquin, in the stove, from June to August, ripening fruit in September and October. It has the tuberous creeping root, and general habit, of the four foregoing species. The *stems* are several, six feet high, perennial, branched, smooth, and shining. *Leaves* several, in two ranks from the root; those of the stem alternate, ovate, about a foot long and four inches wide; their *footstalks* about the same length. *Panicle* erect, of a few alternate zigzag branches. *Bracteas* two-ranked, imbricated, ovate, folded, about an inch long, each enfolding a two-flowered partial stalk, with a much smaller internal bractea. *Calyx-leaves* elliptical, of the same dirty or tawny-yellow as the bracteas. *Corolla* white; the lip three-lobed. *Germen* smooth. Coat of the *fruit* firmly adhering to the nut. Our account is taken from Jacquin's works, but a specimen brought, we believe, from the Brasils, by the late sir G. L. Staunton, agrees with it, as far as we can examine.

6. *M. gracilis*. Slender-spiked Arrow-root. Rudge Guian. 8. t. 3.—Stems simple. *Leaves* ovate, pointed. Spikes terminal, solitary. *Bracteas* imbricated, sheathing, cylindrical.—Native of Guiana, communicated by T. F. Forster, esq. This has the habit of a bamboo, except that the stems are simple, and only a foot high. They are slender, smooth, and leafy. *Leaves* near three inches long, light green, taper-pointed, rounded at the base, smooth, except a hairy line along the nerve on the upper side; their veins transverse, as in the other species, not parallel to the rib, as in the above plate; the knot at their base very slender, hairy on its upper side; sheath ribbed, smooth, dilated upwards. *Spikes* solitary at the tops of the stems, about four inches long, straight, erect, slender, cylindrical, acute, being closely enveloped in five, six, or more, cylindrical, imbricated *bracteas*, about an inch long, from each of which, in succession, spring a couple of *flowers*, whose tube is very long, inclosed in the bractea; the outside of their *calyx* hairy; their *lip*, as far as we can discern, undivided.

7. *M. obliqua*. Oblique-leaved Arrow-root. Rudge Guian. 8. t. 2.—Leaves elliptical, oblique at the point, on very long footstalks. Spikes clustered. Bractees crowded, sheathing, cylindrical.—Found by Mr. Alexander Anderson in the West Indies, according to the Bankian herbarium. Mr. Rudge had it from Guiana. Of the form of the whole plant we are uncertain, but by our specimen it appears herbaceous, the leaves being radical, on footstalks two feet long, sheathing in their lower part, and crowned with a cylindrical, scarcely swelling knot, above an inch in length. The leaf itself is about a foot long, and six inches broad, elliptical or somewhat ovate, terminating in a very short, oblique or lateral, curved point; smooth on both sides; the veins transverse, extremely numerous and close, five times as numerous as in Mr. Rudge's figure. Spikes apparently terminal, three together, either accompanied by a sheathing-stalked leaf, as in the figure just mentioned, or by one common bractea larger than the rest, as in our specimen. Each spike is about a foot long, almost perfectly simple, slightly zigzag, slender, cylindrical, acute, closely enveloped in numerous, alternate, cylindrical, crowded, but scarcely imbricated, hard, downy bractees, above an inch long, each containing two flowers. About half a dozen lanceolate cartilaginous bodies are seen projecting just beyond the point of each bractea, looking like the anthers of a grass. These appear to us the tips of a number of linear, membranous, internal bractees, about three of which surround each flower, and which might be taken for the calyx, were they not inserted below the germen. There are also two or three broad membranous bractees, external with respect to these, but inclosed within the common sheathing one. Of the real calyx or corolla our specimen gives no opportunity of judging. The germen appears to be turbinate, crowned with dense upright hairs. Style compressed, the length of the bractees, with the proper inflexed stigma of the genus. Mr. Rudge represents the corolla as about twice the length of the external bractea, with a long slender tube, and a structure analogous to the preceding species. The lip, it seems, is undivided.

8. *M. spicata*. Long-stalked Spiked Arrow-root. Aubl. Guian. 4.—Leaves ovate-oblong, unequal-sided, oblique at the point, on long footstalks. Spike simple, solitary, on a long stalk.—Gathered by Aublet in a boggy forest in Guiana. One of his leaves was given by sir Joseph Banks to the younger Linnæus, who has, in his herbarium, accompanied it with a rough drawing of the spike of flowers, and a note in Swedish, saying he had "seen four leaves, all of the same strange shape." These materials, though imperfect, are valuable, as Aublet has given no figure of this, any more than of his *M. Arouma*, *humilis*, or *lutea*, about which therefore following botanists have been much in the dark. Our leaf of *M. spicata* is a foot long and three inches broad, smooth and shining, with numerous principal, as well as intermediate, transverse veins; the base is rather unequal, and the two halves of the leaf upwards much more so, one margin being curved, the other straight; the midrib running up perfectly straight till it reaches the former margin, when it turns suddenly into the very short lateral or oblique point. The footstalk is, perhaps, as long as the leaf; bordered or sheathing below; crowned with a cylindrical singly downy knot, an inch long, where it joins the leaf. Spike erect, three inches in length, supported by a very long, round, simple, erect, naked stalk (which we may presume to be radical), and subtended by a large ovate sheathing bractea. Each flower, or perhaps pair of flowers, appears also to have an appropriate much narrower bractea, an inch long, and these bractees are about ten in all, imbricated

in several rows. Aublet says they are firm and coriaceous, and the flowers white.

9. *M. ? Allouia*. Lateral-tufted Arrow-root. Aubl. Guian. 3. (Naru kila; Rheede Malab. v. 11. 67. t. 34.)—Leaves radical, ovate, acute, on long stalks. Head of flowers sessile, from a lateral cleft in the footstalk. We venture to adopt this species from Aublet, because the figure he cites in the *Hortus Malabaricus* gives an idea of what he intends. He found his plant in the same marshy forest with the last. The root is furnished with knobs of various sizes, good to eat when roasted. Leaves radical, large, on long footstalks, some of which bear a lateral tuft of numerous white sessile flowers; a mode of flowering analogous to that of the *Acorus*. The genus however of this species must depend on Aublet's authority. His three others above-mentioned, see n. 8, we must leave in the uncertainty in which we find them.

10. *M. ? comosa*. Leafy-headed Arrow-root. Linn. Suppl. 80. Willd. n. 4. Roscoe Tr. of Linn. Soc. v. 8. 340. (Curcuma nova; Amoen. Acad. v. 8. 251.)—Leaves radical, elliptical, on long stalks. Flowers in a terminal tuft, crowned with leafy bractees.—Sent by Dalberg from Surinam. The leaves have the habit of the last. Both species seem to want the knot at the top of their footstalks, which is a strong presumption of their being no true *Maranta*. Indeed Linnæus himself expresses his doubts of the present plant. The flower-stalk is radical, three feet high, round, simple, smooth and naked, except at the top, where it bears a fine crown of elliptic-lanceolate leafy bractees, like that of an *Eucomis*, under which the flowers are stationed, in sessile drooping tufts. We find their habit and structure very unlike what are proper to this genus, and the stamen is more like that of an *Alpinia*, to which we should, at a venture, remove this plant, without much scruple.

We omit *M. malaccensis*, Willd. n. 3, adopted by that author from Burmann (*Galanga malaccensis*; Rumph. Amb. v. 5. 176. t. 71. f. 1.), as the figure of Rumphius shews it to be, in habit and character, an *Alpinia*, to which genus Mr. Roscoe has referred it in Tr. of Linn. Soc. v. 8. 345. S.

MARANTA, in *Gardening*, contains plants of the herbaceous, perennial, exotic kind, of which the species cultivated is the Indian arrow-root (*M. arundinacea*).

The root of this plant, when washed, pounded fine, and bleached, makes a fine nutritive powder, which is made use of as food in many cases where the stomach is weak and incapable of digesting more solid kinds.

Method of Culture.—All the plants of this species may be increased by dividing the roots and planting them in pots of light rich earth, in the spring, just before they begin to shoot, plunging them in the bark hot-bed of the stove, where they must be kept in general, being frequently refreshed with water, when in a state of growth, having free air, after they become of some strength, admitted to them.

Ornament and variety are afforded by them in stove collections among other tender plants.

MARANTABUAN, in *Geography*, a small island in the East India sea, N. of Borneo. N. lat. 6° 55'. E. long. 117° 29'.

MARASA, a town of Africa, in the kingdom of Wangara, on the Niger. N. lat. 16°. E. long. 17°.

MARASCA, a town of Italy, in the department of the Upper Po; three miles W. of Cremona.

MARASCH, or MERASCH, a town of Asiatic Turkey, and capital of a Sangiacate, under the pacha of Caramania,

nia, and the see of a Jacobite bishop; 140 miles W.S.W. of Diarbekir. N. lat. $37^{\circ} 24'$. E. long. $36^{\circ} 35'$.

MARASIND ISLANDS, two small islands in the East India sea. S. lat. $5^{\circ} 15'$.

MARASKER, a small island on the E. side of the gulf of Bothnia. N. lat. $63^{\circ} 21'$. E. long. $21^{\circ} 25'$.

MARASMUS, in *Medicine*, from *μαρασμεν*, to waste, is a term applicable to every chronic disease, in which great emaciation of the solids take place. A marasmus is said to be present in the last stage of every species of consumption or decline; but the term is more especially used to denote the *mesenteric* consumption, or that species of decline which occurs in children, and originates in derangement of the abdominal viscera. This disease will be found described at length under the article INFANTS, *Diseases of*, § 4.

MARASNA, in *Geography*, a town of Africa, in Wangara. N. lat. $14^{\circ} 52'$. E. long. $16^{\circ} 12'$.

MARAT, JOHN PAUL, in *Biography*, a native of Switzerland, who became a prominent actor in the French revolution, was born in 1744: he went to Paris to study physic, and, probably, not having patience to pursue the profession in a regular course, he became an empiric, selling his medicines at an extravagant price. On the breaking out of the revolution, he took the lead among the most violent and savage of all the factions that disgraced the capital. He published a periodical paper, entitled the "Publiciste Parisien," in which he, without scruple, and without any regard to decency and truth, attacked the virtuous Neckar, and other men eminent for their integrity and public talents. This journal did not last long, but the author had other projects in view, and he next set on foot a paper, entitled "The Friend of the People," in which he unblushingly exhorted the people to revolt, pillage, and murder. He excited the troops to use their arms against their generals, the poor to plunder the rich, and the people at large to rise against the king. After the deposition of Lewis XVI. he was named a deputy of the department of Paris, to the convention, in which assembly he appeared armed with pistols. In April, 1793, he publicly denounced the leaders of the Brissotine party, accusing them of treason against the state; he was supported by Robespierre, a violent tumult ensued, but Marat and his friends were subdued, and himself impeached and prosecuted; in a few days being brought to trial he was acquitted. The triumph of his party was now unbounded, and they soon gained such an ascendancy over their enemies, that they murdered or banished all that attempted to obstruct the progress of their nefarious projects; till at length their leader Marat fell a victim to the enthusiastic rage of a female, Charlotte Cordè, who had travelled from Caen, in Normandy, with a determination of rescuing, as she hoped, her country from the hands of barbarians, by the assassination of one of the chief among them. He died unpitied by every human being who was not of the atrocious faction which he led, having, for some weeks, acted the most savage parts, and been the means of involving many of the most virtuous characters in France in almost indiscriminate slaughter. Previously to joining in revolutionary politics, he was known as an author, and published a work "On Man, or Principles of the reciprocal Influence of the Soul and Body," in two volumes, 12mo: also, some tracts on Electricity and Light, in which he attacked the Newtonian System. New. Ann. Reg. 1793.

MARATE, in *Geography*, a low desert island in the East India sea, about eight miles from the coast of Africa, four miles in circumference. On the S. coast is a good haven, secure from all winds, formed by two points of land, inclosing a spacious harbour, narrow at the mouth, where

lies a very long flat island with some sand-banks: the depth is three fathoms in the shallowest place. N. lat. $18^{\circ} 35'$.

MARATHON, in *Ancient Geography*, a small city of Attica, near the sea, about 40 miles from Athens, famous for the victory of the Athenians over the Persians. The Persian army commanded by Datis consisted of 100,000 foot, and 10,000 horse; that of the Athenians amounted in all but to 10,000 men. This latter had 10 generals, of whom Miltiades was the chief; and these 10 were to have the command of the whole army, each for a day, one after another. It was a subject of great dispute among these officers, whether they should hazard a battle, or expect the enemy within their walls. The latter opinion was that of a great majority; Miltiades and Aristides were for risking an immediate engagement, and this measure was adopted. Aristides, well knowing that a command which changed every day must necessarily be feeble and fluctuating, judged it prudent to vest the whole power in a single person, and in order to induce his colleagues to adopt this plan, he himself set the first example of resignation. When his day of command occurred, he resigned it to Miltiades, as the more able and experienced general. The other commanders followed his example; so that Miltiades had the sole command. When the day of battle arrived, he endeavoured, by the advantage of the ground, to gain what he wanted in strength and number. Accordingly he drew up his army at the foot of a mountain, that the opposing army might not be able to surround him, or charge him in the rear. On the two sides of his army he caused large trees to be thrown, in order to cover his flanks, and render the Persian cavalry useless. As soon as the signal for battle was given, the Athenians ran against the enemy with all imaginable fury, which was the first instance, says Herodotus, in which the Grecians thus began an engagement. The battle was fierce and obstinate. Miltiades had made the wings of his army very strong, but had left the main body more weak and not so deep. As he had but 10,000 men to oppose to a very numerous army, it was impossible for him to make a large front, or to give an equal depth to his battalions. He therefore concluded that he could succeed only by the efforts which he should make with his two wings, in order to break and disperse those of the Persians; not doubting that when his wings were victorious, they would be able to attack the enemy's main body in flank, and complete the victory without much difficulty. This was the plan which Hannibal afterwards followed at the battle of Cannæ. The Persians attacked the main body of the Grecian army, and made their greatest effort upon their front. This was led by Aristides and Themistocles, who supported it for some time with intrepid bravery, but were at length obliged to give way. At that instant came up the two victorious wings, and totally routed the Barbarians. The Athenians pursued them to their ships, set many of them on fire, and took seven. They had not above 200 men killed on their side in this engagement; whereas on the side of the Persians above 6000 were slain, without reckoning those who fell into the sea as they endeavoured to escape, or those that were consumed with the ships set on fire. The Persians had thought themselves so sure of victory, that they had brought marble to Marathon, in order to erect a trophy there. The Grecians took this marble and caused a statue to be made of it by Phidias, in honour of the goddess Nemesis, who had a temple near the place where the battle was fought. The memory of those Athenians that were slain in the battle was honoured by illustrious monuments erected to them in the place where the battle was fought; upon which their own names, and that of their tribes, were recorded. Miltiades's was afterwards erected

erected in the same place. All the honour that was paid to Miltiades, the great deliverer of Athens and of all Greece, was, that in a picture of the battle of Marathon, drawn by order of the Athenians, he was represented at the head of the 10 commanders, exhorting the soldiers, and setting them an example of their duty. This picture was painted gratis by the celebrated Polygnotus, of the isle of Thasos, one of the finest painters of his time, and it was preserved at Athens in a gallery, adorned and enriched with different paintings, excellent in their kind, and done by the greatest masters. The battle of Marathon was fought in the 3d year of the 72d Olympiad, B.C. 490.

In the plain of Marathon, and N.E. of it, was a large lake, which received a river, that ran from the N.W. There was also a mountain of Attica of the same name. Marathon, once so famous, is now an inconsiderable village of European Turkey, in Livadia, consisting only of a few houses, but retaining its ancient name. The spot where the brave Athenians were buried is situated near a lake, from which a river runs into the bay of Negroponte; nine miles N.N.E. of Athens.

MARATHUS, a large and rich town of Phœnicia, situated between Batanea and Carnæa, according to Strabo. This town obtained liberty from one of the successors of Alexander, with the privilege of being governed by its own laws. A war occurring between this city and that of Arad, the inhabitants of the latter place took it, razed it, and divided its territory among themselves.

MARATHUSA, a town in the interior of the isle of Crete.—Also, an island of Asia, upon the coast of Asia Minor, near Ephesus, according to Pliny, but according to Thucydides and Steph. Byz, before Clazomenes.

MARATROCAMPO, in *Geography*, a town of the island of Samos; six miles W. of Cora.

MARATTA, CARLO, in *Biography*, an historical painter, and one of those fortunate men who receive during their lives their full portions of praise and emolument. He was born at Camurano, in the marquisate of Ancona, in the year 1625. He was the disciple and friend of Andrea Sacchi, with whom, to the death of the latter, he pursued his studies, and continued his attachment.

Although he enjoyed during his life, and perhaps deserved, the reputation of the best painter in Europe, yet when compared with the truly great, he never rose above mediocrity. It is very seldom that enlarged and grand conception reigns in his compositions; but a certain suavity and loveliness in his madonnas, which he seems to have acquired from Correggio's works, of grace in his angels, and devout character in his saints, render his pictures always agreeable, and are the source of his renown. From his first performances being chiefly madonnas, his contemporaries treated him with the appellation of Cartuccio delle Madonni, and probably by that very circumstance excited him to employ his talents upon more extended and difficult subjects, in which he exhibited his superior taste and skill. He evidently appears to have studied the works of Raphael, but never felt the beauty of his simplicity, nor understood the principles of his design and composition. For the well understood draperies and judicious introduction of folds which we see in the best pictures of that great master, Maratta resorted to a fulness and overwhelming quantity; arranged in the style of Sacchi; but hiding too much of the figures, and giving them by that means a heaviness, and often a bad proportion. His colouring is in general clean and freely wrought, but sometimes his shadow colour partakes too much of red, which does not unite in a friendly manner with the lighter tones,

and destroys the brilliancy of effect which he generally aims at.

There is a great number of his works in the churches and palaces of Rome, which bear testimony of his popularity, and they were sold at prodigious prices during his life. Of late, since a more just taste in art is arisen, they have fallen in the scale to their proper level; but still are, as they deserve to be, held in much estimation.

He lived to the advanced age of 88, and practised his art to a very late period of his existence.

MARATTIA, in *Botany*, was so named by Dr. Swartz, in commemoration of John Francis Maratti, abbot of Valumbrosa, lecturer on botany, and superintendent of the botanic garden, at Rome. He published three small Latin tracts in that city. First a description of the flowers of doriferous ferns, in 1760, which is rather a description of their fruits; for the author certainly has in some cases mistaken the latter for the former; in others delineated as organs of impregnation, what are, at most, very doubtfully such. Yet this essay occasioned Dr. Swartz to choose a genus of ferns to bear his name; and he has certainly fallen on one of the most singular, distinct, and elegant, in nature. Maratti's second work, printed in 1772, is a definition, with figures, of two supposed new genera, entitled *Romulea* and *Saturnia*; the former of which is *Ixia Bulbocodium*, the latter *Allium Chamæmoly*. His last publication, dated 1776, is on the Zoophytes and Lithophytes of the Mediterranean; of which, considered as plants, he treats systematically, in the Linnæan style, with synonyms. All these tracts are of rare occurrence in England. Swartz. Prodr. 128. Fil. 168. Sims and Kon. Ann. v. 2. 309. t. 10. f. 6. Sm. Plant. Ic. 46. Mem. de l'Acad. de Turin, v. 5. 419. Tracts, 259. Sprengel Crypt. 180. Mart. Mill. Dict. v. 3. (Myriotheca; Juss. 15. Lamarck Illustr. t. 866.)—Class and order, *Cryptogamia Filices*; sect. *exannulata*. Nat. Ord. *Filices doriferae*.

Ess. Ch. Capsules oval, scattered, bursting longitudinally on their upper side, disclosing a row of cells in each division. Involucrum none.

This very remarkable and beautiful genus ranges next in affinity to *DANÆA*; see that article. It differs however essentially, in the capsules being formed of two lobes, at first cohering longitudinally, by what afterwards becomes their upper surface, and discloses a row of from four to ten cells in each lobe, opening each by a separate orifice, smaller than the internal diameter of the cell, in the said upper surface. The entire capsule therefore is oval, with a determinate number of cells, very different from the indefinite aggregation of single-celled capsules, seen in *Danæa*. Nothing is known of the flower, or mode of impregnation. The capsules stand separately on the veins of the frond, without any involucrum, and in a young state appear like little smooth grains. When mature they are generally the size of half a mustard-seed. Their seeds are inconceivably minute.—Five, or at most six, species are known.

1. *M. alata*. Wing-stalked Marattia. Swartz Prodr. 128. Sm. Plant. Ic. t. 46.—Frond doubly pinnate. Leaflets sharply ferrated. General stalk scaly; partial ones winged. Native of Jamaica, where it has been gathered by several botanists. This appears to be an herbaceous fern, perhaps three or four feet high, but we have not seen either the root or the lower part of the frond. The upper part is doubly and oppositely pinnate, with square scaly stalks, the whole of which in the branches, and the upper part of the main stalk, is winged with a leafy entire border, contracted at the insertion of every leaflet. The leaflets are sessile, an inch long, more or less, very nearly, if not entirely, opposite, ovate-

ovate-oblong, bluntish, sharply and rather deeply serrated, especially towards the extremity, veiny, the veins always dividing soon after they leave the mid-rib, each branch ending in one of the serratures. The upper side is smooth, with a prominent rib; under side paler, minutely scaly about the rib and veins. The lower leaflets are often lobed or pinatifid; the upper ones diminish gradually, become confluent, and form an elongated serrated point to each branch. The truly remarkable capsules are three, four, or five on each side of the mid-rib of most of the leaflets, towards the margin beneath, each stationed on a branch of a vein, and about the size of a garden-poppy seed, externally pale brown. When the lobes separate, their upper side appears of a pale sulphur-colour, striated transversely where the cells are to open, and more or less crenate at the edges. At length the whole capsule becomes browner, and the cells open by about five oval-oblong orifices in each lobe.

2. *M. lewis*. Smooth-stalked Marattia. Sm. Plant. Ic. t. 47.—Frond doubly or triply pinnate. Stalks smooth; the partial ones winged. Leaflets bluntly serrated; the uppermost confluent.—Gathered by M. Thierry de Menonville in Hispaniola, not in Dominica.—This has a general resemblance to the foregoing, but is partly triply pinnate, and quite destitute of scales on the stalks or veins. The serratures of the leaflets are blunter; partial stalks of the lower ones very broadly winged; and the capsules are shorter, almost globose before they open, having but four, rarely five, cells in each lobe. Their margin moreover is quite entire, not crenate or cracked. Seeds extremely minute, white. It may also be remarked that the principal subdivisions of the frond in this species are more generally alternate, and the veins of the leaflets are most of them simple, not divided.

3. *M. fraxinea*. Ash-leaved Marattia. Sm. Plant. Ic. t. 48.—Frond doubly pinnate. Stalks smooth, simple. Leaflets alternate, lanceolate, serrated, all distinct.—Native of the island of Mauritius. Our specimen was given by the celebrated M. Thouin to the younger Linnæus, when at Paris. It is one of the most magnificent, as well as curious, of its whole natural order. We have only a branch of the frond, which shews the whole to be at least doubly pinnate, in an alternate order. This branch is above a foot long, and much resembles the leaf of some sort of ash, consisting of 22 alternate sessile leaflets; besides the terminal one, which is not larger than the others. The stalks are very smooth and naked, simple, except a very slight wing near the very top. Leaflets two or three inches long, on very short stalks, smooth, bright green, lanceolate or slightly ovate, scarcely an inch wide in any part; their point elongated; their margin copiously, sharply, and pretty equally serrated; their base wedge-shaped and entire; their transverse veins numerous, parallel, mostly simple, sometimes forked, quite destitute of scales. Capsules disposed near the margin, not very abundantly or universally, rather larger than those of the first species, roundish-oval, brown; each lobe quite entire at the edge, and furnished with about six cells. Dr. Swartz erroneously quotes the author of the present article, as saying the branches (*pinne*) are opposite.

4. *M. forbifolia*. Service-leaved Marattia. "Bory de St. Vincent's Voyage, v. 1. 267." Swartz.—"Frond doubly pinnate. Branches alternate. Leaflets linear-lanceolate." Sw. Native of the isle of Bourbon.—We know this merely by what we have here copied from Dr. Swartz, not having access to the book he quotes. The author we follow suspects this to be the very species figured by Lamarck in his Illustrations of Genera, tab. 866; but we should rather suppose that figure to be taken from *M. fraxi-*

nea, except possibly the separate leaflet. The capsule and its dissections are all copied from Sm. Pl. Ic. t. 48.

5. *M. oppositifolia*. Opposite-leaved Marattia.—Frond . . . Leaflets opposite, linear-lanceolate, sharply serrated.—Native country unknown. We have a mutilated specimen of this, without any mark whatever, in the herbarium of the younger Linnæus. It consists of near four inches only of the rachis, or stalk, which is as thick as a goose-quill, smooth, convex beneath, marked with a narrow furrow above. This appears to be but a very small portion of the branch, or whole frond, we cannot tell which. It bears four pair of opposite leaflets, all nearly of an equal size, not quite four inches long, almost an inch wide, linear-lanceolate, taper-pointed, finely, sharply, and equally serrated throughout, except at the base, veined like *M. fraxinea*, and supported on very short stalks. The upper surface is smooth; the under paler, its veins rough with fine linear scales. Capsules very numerous on every leaflet, rather larger than those of the *fraxinea*, but otherwise like them, and containing the same, or occasionally a greater, number of cells. These capsules form a continued line near each margin, except at the base and point, being from 40 to 50 in each row. We should, by the name, have supposed this the *forbifolia* last mentioned, had the leaflets of that been described as opposite. The shape and size of each leaflet well agree with Lamarck's separate one, fig. b, but his footstalk is too long, and capsules not sufficiently copious or crowded.

6. *M. salicina*. Willow-leaved Marattia.—Frond simply pinnate? Stalk smooth, simple. Leaflets alternate, stalked, linear, very slightly crenate, with serrated points.—Our specimen of this nondescript fern was communicated by the late Rob. Moleworth, esq., as a native of New South Wales. As it was accompanied by a large collection of other plants, undoubtedly the produce of that country, and by no others, we presume the account must be correct; yet there being no *Marattia* mentioned in Mr. Brown's *Prodromus*, cannot but induce some suspicion. It is however a most curious and distinct species. We cannot positively say whether our specimen be the whole plant, from the root; in which case the frond is simply pinnate; or a branch rudely torn from a more compound frond. The stalk is two feet long, smooth, simple and even, somewhat quadrangular, very firm and strong. Leaflets numerous, (about 40), on short stalks, alternate, spreading, linear, sharp-pointed, four or five inches long and half an inch broad; smooth and of a fine green above; rather paler, and having capillary scales on the lower part of the rib, beneath; the margin is so very slightly and obtusely crenate it might almost be called entire, but the short taper point, beyond the capsules, is serrated; the veins are much like the foregoing. The capsules are excessively numerous, forming a close row, along each edge of the leaflet, every vein bearing one, so that there are near 100 in every row. They are larger than in any other known species, and have nearly a double number of cells, whose orifices are linear, and crowded close together.—When we consider the possible rate of increase in such a plant as this by seed, it is as stupendous as that of the Ling-fish, whose progeny, if uninterrupted, would, according to the calculation of Linnæus, in 20 years fill the whole ocean. Here are perhaps 8000 capsules, each having about 20 cells, which makes 160,000, and we can hardly conceive the quantity of minute seeds in each cell; at least it is impossible to count them with any degree of exactness. The number of seeds however in some ferns, is probably much greater.

Not having yet been able to procure the volume of Willdenow's

denow's Sp. Pl. which treats of ferns, we know not how far our new species may accord with any of his. S.

MARATTOUR, in *Geography*, a town of Hindoostan, in the circar of Guntoor; 28 miles N. of Mootapilly.

MARATUBA, an island in the East Indian sea, about 24 miles in length from N. to S. Its breadth varies from 12 miles to 4. It is the largest of a cluster, to which it gives name; the next in size is Kakkabban; the rest are very small. N. lat. $2^{\circ} 14'$. E. long. $118^{\circ} 30'$.

MARAUUA, a town of Arabia, in the province of Yemen; 16 miles N.N.E. of Hodeida.

MARAUDING, from the French, *maraude*, in *Military Language*, is a term applied to a party of foldiers, who, without any order, go into the neighbouring houses or villages, when the army is either in camp or garrison, to plunder and destroy, &c.

MARAVEDI, a little Spanish copper coin, worth somewhat more than a French denier, or half a farthing English.

The word is Arabic, and took its rise from the *Almoravides*, a dynasty of Moors, who, passing out of Africa into Spain, imposed their own name on this coin, which by corruption was afterwards changed into *maravedi*.—Mention is made of it in the decretals, as well as in other Latin writers, under the name of *marabitini*.

The Spaniards also count by maravedis, both in commerce and in their finances, though the coin itself is no longer current among them. Thirty-four maravedis vellon are equal to the real vellon, which is the most general money of account. Madrid, and all Castile, with most of the adjacent provinces, and also Bilboa, Malaga, and Galicia, keep accounts in reals and maravedis vellon. The real of new plate is double the real vellon, and is also reckoned at 34 maravedis of new plate. This real is represented by an effective coin of base silver; but books are not kept in any part of Spain in this money. The real of old plate is also reckoned at 34 maravedis of old plate. Cadiz and Seville keep accounts in reals and maravedis of old plate. The real of old plate is worth about $5d.$; and the real vellon $2\frac{3}{4}d.$ nearly; or, more accurately, $1l.$ sterling = 48 reals $20\frac{1}{2}$ maravedis of old plate, or 91 reals 17 maravedis vellon. See REAL and SPAIN.

This smallness of the coin produces vast numbers in the Spanish accounts and calculation; inasmuch that a stranger or correspondent would think himself indebted several millions for a commodity that cost but a few pounds.

In the laws of Spain, we meet with several kinds of maravedis; Alphonfine maravedis, white maravedis, maravedis of good money, maravedis Combrenos, black maravedis, and old maravedis. When we find maravedis alone, and without any addition, it is to be understood of these mentioned above. The rest are different in value, fineness of metal, time, &c. Mariana asserts, that this coin is older than the Moors; that it came from the Goths; that it was anciently equal to a third part of the real, and consequently of twelve times the value of the present maravedi. Under Alphonfus XI. the maravedi was seventeen times; under Henry II. ten times; under Henry III. five times; and under John II. two times and a half the value of the present maravedi.

MARAVI, in *Geography*, a country of Africa, with a city of the same name, built on the S. side of the lake, about 250 miles from the Indian sea. S. lat. $13^{\circ} 15'$.—Also, a lake of Africa, in S. lat. 10° , of great extent, laid down by M. d'Anville as more than 350 British miles in length, but of inadequate breadth; some say 30 miles. This lake may perhaps, like that of Baikal, lie at the foot of the Table

land on one side, as that of Aquilunda, of much smaller extent, does on the other.

MARAUTSCH, a town of Upper Carniola; 11 miles E. of Stein.

MARAUZGUIR, a town of Hindoostan, in Myfore; 30 miles E.S.E. of Ouffoor.

MARAWA, a town on the east coast of the island of Banca. S. lat. $2^{\circ} 15'$.

MARAWAR, a country of Hindoostan, bordering on the coast opposite to Ceylon; about 60 miles in length, and 40 in breadth. It was conquered by the British troops in 1773, and the rajah killed. It is covered with thick forests, and little cultivated. In the flourishing state of the empire of Hindoostan, Marawar yielded a revenue of five covres of rupees.

MARAWIL, a town of the island of Ceylon, on the W. coast; 14 miles N. of Negombo.

MARAYAN, a town of Hindoostan, in Bahar; 25 miles E. of Bahar.

MARAYAT BAY, a bay on the W. coast of the island of Luçon. N. lat. $14^{\circ} 37'$. E. long. $120^{\circ} 21'$.

MARAZION, or MARKET JEW, a market-town in the parish of St. Hilary, hundred of Penwith, county of Cornwall, England, is situated on the side and at the bottom of a hill, near an arm of the sea, called Mount's bay, three miles E. of Penzance, and 286 W. from London. It derived its principal support, if not its origin, from the resort of pilgrims, and other devotees, to a neighbouring sacred edifice on St. Michael's Mount; but that attraction being counteracted by the changes of opinion which commenced at the Reformation, and the then new town of Penzance drawing within its vortex many merchants and tradesmen, with their connections and dependants, the consequence of Marazion decreased. By some authors its name is derived from the Jews, who are reported to have traded here several centuries ago, and to have held an annual market for selling various commodities, and purchasing tin and other merchandize in return. Richard, king of the Romans, granted two fairs to this town, for the benefit of the priory at St. Michael's Mount; but this charter was superseded by another in the thirty-seventh year of queen Elizabeth, by which the government of the town was vested in a mayor, eight aldermen, and twelve capital burgessees, with power to hold one weekly market and two annual fairs. In the preamble to this charter it is stated, that "Marghasiewe was a trading borough of great antiquity;" from which expression, and from a corroborating correspondence between the sheriff of Cornwall and the mayor of Marazion during Cromwell's protectorate, it seems probable that this town was anciently represented in parliament. Two members were actually elected and returned in Cromwell's time; but they do not appear to have taken their seats: the endeavours of the inhabitants to regain their dormant rights proved ineffectual. In the Survey of the year 1801, pursuant to act of parliament, Marazion was stated to contain 224 houses, occupied by 1009 persons. The trade consists chiefly in the importation of timber, coals, and iron, for the use of the inhabitants of the place, and for the neighbouring mines. The parish-church of St. Hilary is nearly two miles distant from the town; but here is a chapel of ease, supported by private subscription. Quakers and Methodists have also their respective meeting-houses.

Between Marazion and St. Michael's Mount is a place called the Chapel Rock, where the pilgrims who came to visit the priory of St. Michael performed certain devotional ceremonies, in a kind of initiatory chapel previous to their admission to the more sacred Mount.

The peculiar situation of St. Michael's Mount, and the singular character it assumes from appearing to rise immediately from the waves, interest the imagination of the observer; though, when viewed from the land, its magnitude is apparently diminished, from the vast extent of the horizon, and the expanse of water which surrounds its base. At high tides it appears a completely insulated assemblage of rocks, rising to a considerable height, and gradually decreasing in size, till, assisted by the tower of the chapel on the summit, it assumes the form of a perfect pyramid. At low water it may be approached from the shore over a causeway of sand and rock, which is submerged by every rising tide, and the Mount again rendered a perfect island. Some of the masses of rock in the intermediate space are very large, and all are composed of granite of a close texture, with its felspar of a pink colour. The Mount itself consists of a hard granite, in which transparent quartz is the preponderating substance. The origin of the Mount, and its first consecration to religious purposes, are unknown: the earliest time in which it appears on record, as a place of devotion, is the fifth century; though it seems probable that it was then highly celebrated, as St. Keyna, a holy virgin, daughter of Braganus, prince of Brecknockshire, is stated to have come hither on a pilgrimage about the year 490. Upwards of 500 years afterwards, Edward the Confessor founded on this spot a priory of Benedictine monks, on whom he bestowed the property of the Mount. This priory was held in high estimation, and was formed with peculiar privileges by pope Gregory, in the year 1070. King Henry VI. granted the priory to King's college, Cambridge; and it was afterwards bestowed by Edward IV. on the nunnery of Sion, Middlesex. At the dissolution, its revenues, valued at 110*l.* 12*s.* per annum, were conferred, together with the government of the Mount, then a military post, on Humphry Arundel, esq. a branch of the family from which the present lord Arundel is descended. After several transfers, it was, about the close of the seventeenth century, sold to John St. Aubyn, esq., whose descendant, sir John St. Aubyn, bart. still possesses it. The Mount has been the scene of several military transactions: the earliest recorded was in the reign of Richard I. when it was fortified in support of prince John, then earl of Cornwall, in his endeavours to usurp the throne during the king's absence in the Holy Land, or his subsequent imprisonment in Germany. "From this time forward," Carew says, "this place continued rather a school of Mars than a temple of peace." It was a long time defended against Edward IV. by John, earl of Oxford, in behalf of king Henry. During the Cornish insurrection in the reign of Edward VI. the Mount was the refuge of many of the superior families, who were here besieged by the rebels. The civil contentions in the reign of Charles I. were the cause of the fortifications of the Mount being increased, till, according to an historian of that time, they were "impregnable, and almost inaccessible." They were, however, reduced, after a vigorous defence by the king's adherents, in April 1646, by colonel Hammond, who obtained great celebrity by a service of such difficulty and danger. This was the last military occurrence that took place on this romantic spot, whose inhabitants appear to have been then driven away; for at the commencement of the last century, here was but one dwelling-house besides the fortrefs: The improvements that have since been effected, and the increase of the buildings, are to be attributed to St. John St. Aubyn (grandfather of the present baronet), who, about the year 1726, rebuilt and enlarged the pier, so as to contain upwards of fifty small vessels. The security thus given to fishing-boats,

induced several inhabitants of Marazion to erect some houses at the bottom of the rock: the number has been since augmented to seventy, occupied by about 250 persons. The circumference of the Mount is rather more than a mile; and its height, from the sand to the top of the chapel-tower, as ascertained by Hadley's quadrant, is 250 feet, being 48 feet higher than the Monument in London. The distance from the shore at Marazion is about 400 yards. The ascent to the top of the Mount is by a steep and craggy passage fronting the north, defended about the midway and near the top by batteries. The whole summit is occupied by the remains of the ancient monastic buildings, which have been improved and beautified by the present possessor, under whose direction the chapel has been repaired. Beauties of England and Wales, vol. ii.

MARBAA, a town of Arabia; 10 miles W. of Mecca.

MARBACH, a town of Saxony, in the circle of Erzgebürg; 8 miles N. of Freyberg.—Also, a town of Austria, near the Danube; 9 miles S.W. of Aggfbach.

MARBACK, a town of Sweden, in the province of Smaland; 20 miles E.S.E. of Jonkiöping.

MARBASIS, in *Botany*, a name given by some to a kind of plant which they say climbed up trees, and there hung down from their branches in form of long jointed and naked filaments.

The word seems to be only a corruption of the word *anabasis* of Pliny, which he calls also *ephedra*, and gives the same character to.

The marbais of the ancients seems to mean our *usnea*.

MARBECK, JOHN, in *Biography*, organist of Windfor. The premature reforming zeal of this musician nearly made a martyr of him, in the time of Henry VIII. He had indeed the honour of being brought to the stake, with three other persons, who were actually burnt for heresy; but was pardoned at the intercession of sir Humphrey Forster.

Fox, in his "Acts and Monuments," and Burnet, "History of the Reformation," give a circumstantial detail of the troubles in which Marbeck was involved, on account of religion. He however survived Henry, and not only saw the reformation completed, but in 1550 was the first to publish the whole English cathedral service, including the preces, prayers, and responses, set to musical notes under the title of

The Booke of Common Praier, noted 1550. Printed by Richard Crafston, Printer to the King's Majestie, *cum privilegio ad imprimendum solum*.

Marbeck was admitted, in 1549, to the degree of bachelor in music, at Oxford, according to Anthony Wood (Facts Oxon.) who erroneously calls him James Marbeck. He is honourably mentioned by Bate, because he had been persecuted by the Catholics; and his name is omitted by Pitts, for the same reason. See MUSIC A CAPPELLA, and CHANTING.

MARBELLA, in *Geography*, a sea-port of Spain, in the province of Granada, on the coast of the Mediterranean, beautifully situated in a valley, with its harbour screened from the E. wind by a promontory, and defended by a castle, which is furnished with some guns. The exports from this town are wine, dried raisins, leather, black stone, charcoal, and wood. In its neighbourhood is an extensive sugar plantation; 26 miles S.W. of Malaga. N. lat. 36° 31'. W. long. 4° 59'.

MARBEUF, a town of the island of Corsica; 10 miles W.S.W. of Vico.

MARBLE, in *Technical Mineralogy*, those finer varieties of granular and compact limestone, which, being of a closer grain, are susceptible of a superior polish, and are remarkable either for their whiteness, or the beauty and variety of their colours. In former times the appellation of *Marmor* (de-

MARBLE.

rived from the Greek *μαρμαίρειν*, to shine, or glitter, and afterwards corrupted to *marmol*, *marmel*, *marble*, *marbre*,) was indiscriminately given to many stony masses that admit of being polished, and accordingly we find alabaster, serpentine, basalt, porphyry, &c. described under that name, which is now confined to such massive carbonats of lime as come under the above definition; which, however, does not exclude the varieties containing foreign substances imbedded in, or mixed with, the principal calcareous mass, such as serpentine, hornblende, quartz, &c.

Most of the external, physical, and chemical characters of the pure marbles are, of course, the same as those of *compact and granular Limestone*; which see.

Marbles are easily distinguishable from gypseous and calcareous alabasters, with which they are frequently confounded; from the former by the application of some diluted nitric or muriatic acid, which produces a strong effervescence, by expelling the carbonic acid; from the latter (which belong to stalactitical limestone, and are, therefore, acted upon in the same manner by the acids) by inferior hardness, a slighter degree of translucidity, and, if coloured, by the absence of regularity in the stripes and undulations that characterize the calcareous alabaster: nor is the latter ever found in masses of considerable dimensions.

The specific gravity of marble varies in the same manner as that of the different varieties of common limestone, whence no distinctive character can be derived from it: Wallerius and Gmelin state the specific gravity of the former to be less, while others consider it as greater than that of common limestone; but, according to Gerhard and other writers, it is, on the whole, equal in both.

Some granular marbles, when cut into thin slabs, exhibit a degree of elasticity or flexibility, similar to that of the well-known sandstone found in Brazil. This phenomenon was first observed in some pieces of marble preserved in the palace of prince Borghese at Rome. But afterwards another marble, (of the variety called Dolomite,) having the same property, was discovered by Fleuriau de Bellevue, in the Val-Levantine of mount St. Gothard. Dolomieu (who described the Borghese marble) is of opinion that this property is owing to a state of desiccation which has lessened the adherence of the molecules of the stones; and Fleuriau de Bellevue has proved this conjecture to be well founded, not only by the appearance and nature of the stone he discovered on St. Gothard, but also by his imparting the same property to several inflexible varieties of marble by merely exposing them to such a degree of heat as produced complete desiccation. Some wrought granular (statuary) marbles acquire a similar property after a long exposure to the action of the atmosphere and the solar rays; a circumstance which sometimes takes place in statues, causing thereby the more projecting parts to exfoliate, and to crumble to pieces. Dolomieu has first made this observation on an Italian marble called *Betullio*.

The various tints of the uni-coloured and variegated marbles, are generally produced by oxyds of iron, the solution of which has, either wholly or partially, penetrated the mass previous to its complete induration. Blue and green marbles often owe their tints to minute particles of hornblende; this is the case, for instance, with the slate blue variety called *turchino*, and with some green German marbles. The black varieties are coloured by charcoal, and also by bitumen, when they pass into flintstone. In marbles containing petrifications, these appear sometimes to have derived their colour from the same fluid which coloured the mass; while at other times the colour of the ground is quite different from that of the petrifications it contains.

All that has been said of the fracture of granular and compact limestone, is applicable to marbles; but it is often difficult to draw the line between the two former. In general it may be said, that the white statuary marbles belong to the granular, and many of the variegated to the compact. Nor is it in all cases easy to determine whether a given specimen belong to the older or newer formation of limestone. It is, therefore, evident, that the division of marbles into primary, with shining fracture, and into secondary, with dull fracture, is far from being practically useful; indeed, many varieties of marbles, as for instance, most of those of the Hartz, &c. cannot be referred to either.

Baumer, Bertrand, Scopoli, Daubenton, Gmelin, and others, have arranged the varieties of marble after the colours they present; but this system must necessarily assign two or more different places to one and the same kind of marble, variable in the number of its colours, and is, therefore, applicable only to small specimens. A far more convenient and useful distribution is the one adopted in the "*Traité des Pierres précieuses, &c.*" by Brard, whom we shall follow in the present article. The marbles are by this author divided, according to their localities, into classes, and these subdivided each into eight distinct divisions, *viz.*

1. Uni-coloured marbles: this division contains only the white and the black marbles.

2. Variegated marbles: those with irregular spots and veins.

3. Madreporic marbles: this division, established by Faujas, comprehends all marbles containing remains of madreporas, or of related animals which generally present themselves in the shape of white or grey spots, with regularly disposed dots and stars in the centre.

4. Shell marbles: marbles that contain only a few shells, and are not, like

5. Lumachella marbles, entirely composed of shells.

6. Cipolin marbles: containing veins of greenish talc:

7. Breccia marbles: formed by a number of angular fragments of various marbles united by a cement. These are subdivided into *small breccias*, with spots having generally less than an inch in diameter; and into *large breccias*, with the generality of spots exceeding that dimension.

8. Puddingstone marble: formed, like the breccias of fragments united by a cement, but which, instead of being angular, are rounded.

A. *Antique Marbles.*

Antique marbles are such as were made use of by the ancients, and the quarries of which are no longer known. The most remarkable of these, both on account of their beauty and the use made of them in the arts, are

Parian marble (Lychnites of the ancients). Of a yellowish-white colour; texture fine scaly; scales shining and placed in all directions. Dipœnus, Scyllis, Malas, and Micciades employed this marble, and were imitated by their successors. The ancients called it lychnites, because its quarries were wrought at lamp light. The principal statues of Parian marble still extant are, the Venus of Medicis, Diana venatrix, Venus leaving the bath; the colossal Minerva (called Pallas of Velletri), Ariadne (called Cleopatra), Juno (called Capitolina), &c. It is also Parian marble on which the celebrated tables at Oxford are inscribed. See *ARUNDELIAN and PARIAN Marbles*.

Pentelic Marble, from mount Pentelcus near Athens. This marble much resembles the preceding, but is more dense and fine-grained; it sometimes exhibits faint greenish zones, produced by greenish talc, whence the Italian name *Cipolino statuario*. The principal monuments of Athens were of *Pentelic*

telic marble, such as the Parthenon, the Propylees, and the Hippodrome. Among the statues of this marble in the Napoleon Museum, at Paris, are the Torfo; a Bacchus in repose; Jason, (called Cincinnatus); a Paris; the Discobolus reposing; the bas-relief known by the name of the Sacrifice; the throne of Saturn; the tripod of Apollo; and the two beautiful Athenian inscriptions known by the name of "Nointel Marbles," because M. Nointel caused them to be brought from Athens to Paris in 1672.

Greek white Marble. The marble to which the statues of Rome give the name of *Marmo Greco*, is of a very bright snow-white colour, close and fine-grained, and of a hardness which is rather superior to that of other white marbles. It takes a very fine polish. This is one of those varieties which, being found near the river Coralis, in Phrygia, were called corallitic or coralline marble by the ancients. According to Pliny it was found in Asia, in masses of small dimensions; and Argenville maintains that a similar kind occurs on mount Caputo, near Palermo, in Sicily. The Greek marble was obtained from several islands of the Archipelago, such as Scio, Samos, &c.; that of the island of Lesbos or Metelin sometimes presents spots on its surface. Among the statues of this marble in the Napoleon Museum, the most remarkable are; a Bacchus, Zenon the philosopher, as also the bust known by the name *Faune à la tache*. Brard observes that this latter bust appears rather to be of the true Coralic marble of the ancients; and that the spot at the neck, from which the bust has derived its name, is foreign to the marble, and caused by contact with a piece of copper. Some suppose the Apollo of Belvedere to be of Greek marble, but the general opinion is that it is marble of Luni.

Translucid white Marble (*Marmo statuario* of the Italians.) This much resembles Parian marble, but differs from it by its more considerable translucidity. There are at Venice, and in several other towns of Lombardy, columns and altars of this marble, the quarries of which are perfectly unknown.

Flexible white Marble, of a beautiful white colour, and fine grain. There are five or six tables of it preserved in the house of prince Borghese at Rome; their length is about two feet and a half, the breadth about ten inches, and the thickness a little less than three. They were dug up, as the abbé Fortis was told, in the feod of Mondragone. Being set on end they bend, oscillating backward and forward; when laid horizontally, and raised at one end, they form a curve, beginning towards the middle; if placed on a table, and a piece of wood laid under them, they make a salient curve, and touch the table with both ends. We refer to what has been said above respecting this property.

White Marble of Luni, on the coast of Tuscany. It is of a splendid white, and of a fine and close grain; it takes a very fine polish, and may be employed for the most delicate work, whence it was preferred by the Grecian sculptors both to the Parian and Pentelic marbles. It appears to be even finer than that of Carrara, and is moreover free from those grey veins which are not unfrequently found in the latter. Most mineralogists coincide in their opinion that the Apollo of Belvedere is of Luni marble; but the Roman sculptors look upon it as Greek marble. Of the Grecian statues of this marble in the Napoleon Museum, the most remarkable are, the Antinous of the Capitol; the Antinous in bas-relief; the bas-relief representing the ceremony of the conclamation.

White Marble of Carrara, between Specia and Lucca. Of a fine white colour, but often traversed by grey veins, so that it is difficult to procure middle-sized pieces without them; its fracture is granular and shining, and its grain fine

enough for the purposes of sculpture. It is not so subject to turn yellow as the Parian marble. This marble, which is almost the only one made use of by modern sculptors, was also quarried and wrought by the ancients, as is proved by the great number of antique statues still extant in this marble. Its quarries are said to have been opened in the time of Julius Cæsar. At present its two principal quarries are those del Pisanello and del Polvazzo. In the centre of the blocks of this marble very limpid rock-crystals are sometimes found, which are called Carrara diamonds. It is also sometimes, like the Pentelic marble, traversed by veins of a greenish talc, when it is called in Italy *Cipolinaccio di Carrara*. The average price of this marble is seventy-two livres the cubic foot.

White Marble of Mount Hymettus in Greece. This is not a very pure white variety, but inclines a little to grey. Pliny informs us that Lucius Crassus, the orator, was exposed to the sarcasms of Marcus Brutus, because he had adorned his house with six columns, twelve feet high, of Hymettian marble. The statue of Meleagre, in the Napoleon Museum, is of this marble.

These are the chief white marbles which the ancients used for the purposes of architecture and sculpture. The Thasian and Arabian are likewise mentioned as antique white marbles, but we are not acquainted with any monuments executed in them.

Black antique Marble (*Nero antico* of the Italians.) This differs from the modern black marbles by the superior intensity of its colour; so much so, that if placed beside those of Dinan and Namur, it makes them appear grey. It has been affirmed that the ancients procured this marble from Greece; what we know for certain is, that Faujas has rediscovered quarries of real antique black marble that were wrought by the ancients, and of which the remains are still to be seen at the distance of two leagues from Spa, towards Franchimont, not far from Aix-la-Chapelle. This marble is extremely scarce, and occurs only in wrought pieces.

Red antique Marble (*Rosso antico* of the Italians, *Ægyptum* of the ancients.) This beautiful marble is of a deep blood-red colour, here and there with white veins, and if closely examined is found to be sprinkled over with minute white dots, as if it were strewn with sand. Of this kind is the Egyptian Antinous in the museum at Paris. But the most esteemed variety of rosso antico is that of a very deep red, without any veins, such as it is seen in the two antique chairs, and in the bust of an Indian Bacchus, in the same museum. The white points, which are never wanting in the true red antique marble, distinguish it from others of the same colour, such as the griotte, &c. It is not known from whence the ancients obtained this marble; the conjecture is that it was brought from Egypt. There is in the Grimani palace at Venice, a colossal statue of Marcus Agrippa in rosso antico, which was formerly preserved in the Pantheon in Rome.

Green antique Marble (*Verde antico* of the Italians.) This may be considered as a kind of breccia, the paste of which is a mixture of talc and limestone, and the dark green fragments are owing to serpentine more or less pure. The verde antico of the best quality is that of which the paste is of a grass-green, and the blackish spots are of that variety of serpentine which is called noble serpentine. This marble is much esteemed in commerce, but large pieces of a fine quality are seldom seen. There are four fine columns of it in the Napoleon Museum; but much more beautiful ones are preserved at Parma. It was known to the ancients under the name of marmor Spartum or Lacedæmonium. This verde antico, properly so called, must not be confounded with the

M A R B L E.

marbles known by the names of *vert-de-mer*, or *vert d'Egypte*. The real verde antico is a breccia, and is never mingled with red spots, while those just mentioned are veined marbles mixed with a dull red substance, which gives them a brownish hue.

Red spotted green antique Marble.—Its ground is very dark green, here and there marked with small red and black spots. It also contains fragments of entrochi changed into white marble. The quarries of this marble are lost, and it is found only in small pieces, which are made into tablets, &c.

Leek Marble (Marbre poireau of the French lapidaries). This is likewise a mixture of limestone and a talcose substance of a light green, shaded with a blackish-green, and related to serpentine. Its texture is filamentose, and as it were ligneous; its fragments are splintery. When polished it exhibits long green veins. Like all other talcose marbles it soon decomposes in the open air. There is a table of it in the hotel de la Monnoie at Paris. Its quarries are lost to us.

Marmo verde pagliocco of the Italians. This marble, which is of a yellowish-green colour, is only found in the ruins of ancient Rome.

Marbre petit antique of the French lapidaries. It is traversed by white and grey veins, the two colours being disposed in uninterrupted threads; the tables made of this marble are irregularly striped their whole length, which has a very fine effect. It is much esteemed, and only made use of for inlaying ornamental furniture. Its quarries are unknown.

Blue antique Marble.—This belongs to the variegated marbles. It is of a reddish-white colour, with slate blue spots representing festoons. It is very scarce, and only seen in small tablets. The quarries of this marble are lost.

Ceruelas Marble.—Of a deep red, with very numerous grey and white veins, from the colour and disposition of which its name is derived. It is much esteemed in commerce, and is said to be found in Africa.

Yellow antique Marble (Giallo antico of the Italians). Of this we have three varieties: the first has more or less the colour of the yolk of an egg, and is nearly of a uniform tint; the other is marked with black or deep yellow rings, and the last is merely a paler coloured variety of the first. These different marbles, for which the Sienna marble is a good substitute, are found only in small detached pieces, and in antique inlaid work. It is in this manner that the two tables of lazulite in the Napoleon Museum are surrounded by a border made of the deep yellow variety.

Red and white antique Marbles.—These marbles, to which separate names have been given, are not sufficiently distinct from each other to require separate articles. The following are from Ferber's letters: red and white marble, called *Porta santa fiorita*, because it was employed for ornamenting the door of St. Peter's church at Rome.—*Seme santo*, or *Arlecchino*, the spots of which resemble seeds, is made use of for several holy buildings.—*Pavonazzo*; white with red spots resembling ribbons.—*Marmo occhio di pavone*; red, white, and rather yellowish. Ferber mentions a number of other red and white antique marbles, such as the Serpentello, Rosso annulato, Purichiello, Vendurino, Fiorito, Cotonello, &c. which are only found among the ruins of the ancient monuments in Rome.

Marble called *Grand Antique*. This variety, which is a breccia, containing some shells, consists of large fragments of a black marble, united by veins or lines of shining white. This superb marble, the quarries of which are lost, is sometimes found in detached pieces and wrought. There are four columns of it in the museum at Paris. A less valuable va-

riety is that in which the spots, instead of being an entire intense black, are of a grey colour.

Antique Cipolin Marble.—Cipolin is a name given to all such marbles as have greenish zones caused by green talc; their fracture is granular and shining, and shews here and there plates of talc. They are never seen to contain marine bodies. The ancients have made frequent use of the Cipolin. It takes a fine polish, but its ribbon-like stripes always remain dull, and are that part of the marble which first decomposes when exposed to the open air. There are modern Cipolins as fine as that used by the ancients.

Purple antique breccia Marble (Brèche d'Allep or d'Alet of French lapidaries). This should not be confounded with the African breccia. There is perhaps no marble, the colour and spots of which are so variable as that of the violet breccia. The following are the chief varieties. The first is that from which the name of the marble is derived; it has a purplish-brown base, in which are imbedded large angular fragments of a light purple colour, and others of a white colour. This first variety can be employed only in large works, on account of the size of its spots, which are sometimes a foot in diameter. There is a beautiful table of it in the Musée Napoleon. The second variety is as it were the miniature of the first; it exhibits the same spots, but within a much narrower compass, so that it may be used for less gigantic works than those for which the other is employed. The third variety is known in commerce by the name of rose-coloured marble (*marbre rose*); in this the spots, instead of being white and light purple, have a very pleasing rose colour. It is scarce and never seen in large pieces. The fourth, which is the most beautiful, appears, at first view, to be perfectly distinct from the others, but it is nevertheless a mere variety of the purple breccia: its ground is of a yellowish-green colour, and the spots, which are of various sizes, are white, green, purplish, and yellow mottled with red; these various spots are traversed by straight lines of a greyish-white colour. This fourth variety is very scarce; there are, however, two tables of it at Paris, one at M. Faujas, the other in the possession of M. Dédre. From one of the names by which this precious marble is known, we see that the neighbourhood of Aleppo in Syria is supposed to be the place where it is found; but this is erroneous, for Brongniart informs us that the name is derived from a place called Alet, near Aix, in France.

African breccia Marble, (called antique African breccia.) Its ground is black, variegated with large fragments of a greyish-white, of a deep-red, or of purplish wine colour; but these latter are always smaller than the former. This is one of the most beautiful marbles existing, and has a superb effect when accompanied by gilt ornaments. Though rather less vivid in its colours than the preceding violet breccia, it is yet, upon the whole, more beautiful. Whether Africa is the part of the world where it is found, as its name implies, is not certain. The pedestal of Venus leaving the bath, and a large column, both in the Napoleon Museum, are of this marble.

Rose-coloured antique breccia Marble.—The base of this small breccia is light red, and variegated with small rose-red spots, and other still smaller spots of a deep black colour; there are some other middle-sized spots of a beautiful white; the whole producing a very pleasing mixture. This marble, of which the locality is entirely unknown, is very scarce, and only small tablets are seen of it in collections.

Yellow antique Marble Breccia.—Two varieties may be united under this name; the one known in Italy by the name of *Giallo brecciato*, which is of a light yellow colour, ornamented

MARBLE.

ornamented with much deeper coloured spots; the other, called *Breccia dorata*, presents yellow spots separated by red intervals, which contain small white spots. Both are found only in small pieces among the ruins of ancient Rome.

The *Arlequin breccia*, or *Brecciato traccagnina* of the Italians. The ground of this antique breccia, which, on account of the roundness of its spots, approaches to the pudding-stone marbles, is of a pale yellow, and contains a number of small fragments of marble of all colours, which has procured it its name. There are two columns of it in the Napoleon Museum.

Red and white breccia Marble (*Brescia favonazza* of the Italians.) Its base is white, the fragments are red. According to Ferber, the interior of the Museo Clementino is ornamented with this marble, the quarries of which are lost.

Breccia di Porta Santa, so called from the use that has been made of it for adorning the door of St. Peter's church in Rome. It is a mixture of unequal, white, blue, red, and grey spots.

Marbre brèche vierge antique of the French lapidaries. This small antique breccia, of a chocolate-brown colour, is spotted with a multitude of minute angular fragments of white marble, besides which it contains some small red spots. It is so scarce that only one tomb is known to exist of it in Rome. Small tablets of it are sold at a very high price.

Peach blossom Marble (*Marmo fior di Persica* of the Italians.) This antique marble is to be referred to the breccias, of which it has all the characters. It exhibits large purplish spots, united by a white cement. A column made of it is preserved in the Napoleon Museum. Several other marbles pass under the name *fior di Persica*, that have no resemblance to the one here described, which is very scarce. Brard suspects that it is nothing but a variety of the purple breccia.

Yellow lumachella Marble, called also *lumachelle Castreani*. Its base is of a very deep brown colour, and contains a great number of shells, forming a sort of well-defined small circles of a very lively orange-yellow. This beautiful marble is very scarce, and occurs only in small tablets. It is often called *lumachella* of Afrachan, and supposed to be found in the neighbourhood of that city; but this is erroneous. D'Argenville and others affirm that small pieces of it are dug up among the ruins of ancient Rome.

Black and white antique lumachella Marble, (called *panno di morto*, the funeral pall.) Its base is of the deepest black, sprinkled with white shells, like snails, from an inch to eighteen lines in length, and distributed rather regularly all over its surface. This shell-marble, the locality of which is unknown, ranks among the finest of its kind, on account of the beauty of its colour, the neatness and distinctness of its spots, and the exquisite polish it takes. It is, moreover, very scarce, a circumstance which much enhances its value.

B. Modern Marbles.

BRITISH MARBLES.

Great Britain is by no means poor in fine varieties of marble, as has been insinuated by some writers on this subject; though, on the other hand, it must be confessed that those are equally wide of the truth who imagine that its marmoric treasures will ever rival those of Italy, Spain, or France. There can be no doubt, however, that the number of British marbles we are at present acquainted with,

will be considerably augmented when accurate research shall have been extended to those parts of the united kingdom, that are most likely to furnish this interesting subject of economical mineralogy.

ENGLISH MARBLES.

Black marble is found in Derbyshire, at Ashford, Matlock, and Monksdale.

Black and white marble in the north part of Devonshire; the varieties from Bridestow, South Tawton, and Drewsteignton, are some black, others inclining to blueish-black. Some of the Chudley marble, and those of Staverton and Berry pomeroy, have a black ground, with large veins of calcareous spar traversing it in all directions; also red, straw-coloured, and greenish veins are seen in it. Black with white veins occurs at Buckfastleigh, and black with yellow and white veins at Bickington, near Ashburton, in the same county. Intense black marble, with distant white spots, is found also in Somersetshire.

The variegated marbles of Devonshire are generally reddish, brownish, and greyish, variously veined with white and yellow, and the colours are often intimately blended. At Waddon there is a quarry of dunnish coloured marble veined with green; there is another at Cheriton. The marbles from Torbay and Babbacombe display a great variety in the mixture of their colours, so much so that one and the same block often exhibits samples very distinct from one another both in tint and delineations.

The Plymouth marble is principally of two sorts; one ash colour, shaded with black veins; the other blackish-grey and white shaded, in concentric stripes interspersed with irregular red spots.

The cliffs near Marychurch exhibit marble not only of great extent, but of superior beauty to any other in Devonshire; being for the most part either of a dove-coloured ground with reddish-purple and yellow veins, or of a black ground mottled with purplish globules. In a valley below the cliff, about 400 yards wide, there are loose unconnected rocks of this marble, owing their situation probably to the falling down of the ground into the sea; for there are very large rocks even on the beach. The huge fragments of rock scattered over the valley, by which we easily descend to the sea, give it a grotesque appearance, and have been whimsically called a petrified congregation; and the pleasantry of this fancy has been heightened by a rock, supposed to be about forty tons, in a very erect position, which has been, ludicrously enough, entitled "the parson." Polwhele's Devon.

The green marble of Anglesea is not unlike the *verde antico*; its colours are greenish-black, leek-green, and sometimes dull purplish, irregularly blended with white; but they are not always seen together in the same piece. The white part is limestone; the green shades are owing to magnesian stones, among which is also asbest in narrow veins. This is an elegant marble, but apt to be intersected by small cracks; nor is it susceptible of a high polish in those places where there are asbestine veins. The quarry is situated on the lands of Monachy-ty, in the parish of Llanfair-Ynghornwy, and is found again in the isle of Skerries, off this parish.

There are several fine varieties of marble in Derbyshire, particularly such as are composed of petrifications. The largest quantity of the mottled grey marble is got in the neighbourhood of Moneyash. It may be distinguished into two kinds; the ground of the one is light grey, and that of the other has a slight blueish cast. The former is rendered extremely beautiful, by the number of purple veins
which

which spread upon its polished surface in elegant and irregular branches. But the chief ornament of the mottled grey marble is the number of entrochi with which it abounds. The longitudinal and transverse sections of them produce an almost incredible variety in its figure. The purple veined marble is got at Ricklowdale near Moneyath; that with the blueish ground at the village itself. There is another variety at a small distance from hence, at a place called Highlow; it is known by the name of *Birdeye marble* (Pilkington.) The marble of Purbeck, in Dorsetshire, is composed of fragments of shells, united by a compact limestone, partly of a yellow colour, and mingled with a greenish martial earth, and black and yellowish particles of bitumen.

A shell marble, which is far from being beautiful, but which in former times has been much employed for architectural purposes, is the *Petworth marble*, from a place of that name in Suffex. It is thus described by Woodward: "The ground grey, with a cast of green. 'Tis very thick set in all parts of it with shells, chiefly turbinated. Some of them seem to be of that sort of river shell that Dr. Lister (Hist. Coch. Angl. p. 133.) calls *cochlea maxima, fusca f. nigricans, fasciata*. Several of the shells are filled with a white spar, which variegates and adds to the beauty of the stone. That spar was cast in the shell before this was reposit in the mass of marble, as is demonstrable from a view of this and other like masses. This is of about the hardness of the white Genoese marble. The slender round scapi of the pillars of the abbey church in Westminster, and of the Temple church, are of this sort of marble. So likewise are those of the cathedral church of Salisbury. Some persons that are less skilful in these matters, fancy these scapi that occur in most of the larger Gothic buildings of England are artificial, and will have it that they are a kind of fusil marble, cast in cylindrical moulds. Any one who shall compare the grain of the marble of those pillars, the spars and the shells in it, with those of this marble got in Suffex, will soon discover how little ground there is for this opinion, and yet it has prevailed very generally. Camden has entertained the same notion of those vast stones of Stonehenge; but is fully refuted by Inigo Jones. Stonehenge restored, p. 33."

SCOTTISH MARBLES.

Scotland abounds in marbles, but only a few of them are generally known. A particularly fine variety of white marble is found, in immense beds, at Assent in Sutherland, out of which blocks of any size may be cut. The best sort is seen in the bed of the river, about a mile or two south of the church.

Mr. Williams, in his Natural History of the Mineral Kingdom, points out several other places where he has seen excellent varieties of marble. An exquisite saline marble of a pure white occurs near Blairgowrie in Perthshire, not far from the high road side, towards the north; it may be easily raised in blocks and slabs perfectly free of blemishes, and in every respect fit to be employed in statuary and ornamental architecture.

Another white marble, composed of fine shining broad grains, like spangles, may be seen in the duke of Gordon's lands, in the forest of Glenavon; but the situation is remote and difficult of access.

A beautiful ash-grey marble, of a fine uniform grain, and susceptible of a fine polish, presents itself in Lochaber, on the north side of the ferry of Ballachylish. It is finely sprinkled throughout with grains of bright pyrites, and also contains disseminated lead ore of a fine texture, which to

the eye appears to be rich in silver. This marble is capable of being raised in blocks of any size.

A black variety flowered with white, is found in the farm of Blairmachyldach, about three miles south of Fort William, in the bed of a river. It is of a close grain, but not very hard; the flowering in it is light and beautiful, like fine needlework, or rather resembling the frosty fretwork on glass windows in a winter morning; and diffused through all parts of the mass.

A dark brown variety beautifully variegated with white, is mentioned by Dr. Meeke, as being found in the parish of Cambuslang, in the county of Lanark. Of this marble, which takes a very good polish, there are several slabs in the palace of Hamilton; a chimney-piece in the college library of Glasgow, and three pair of solid *jambes* in Mr. Dundas's house at Duddinstoun. The stratum, which has been hitherto seen, is from six to twelve inches thick, and extends over a considerable part of the parish.

Also the red and white marble of Boyne; and the white with long veins of a different tint from Durness, are mentioned by authors.

Professor Jameson describes some varieties of marble found in the island of Skye. A white marble veined with ash-grey; it is very heavy, and by exposure to the air it wastes down into a powder. An ash-grey variety, variegated by beautiful lemon-yellow stripes which traverse it in different directions, and which seem to be owing to an intimate combination of chlorite, or hornblende, with the marble. A variety of a pure white colour, with a slight admixture of blueish-grey, in which alone it differs from the fine marble of Carrara.

But one of the most beautiful varieties is that from the hill of Belephetrich in Tirie, one of the Western islands of Scotland. It is now generally known by the name of *Tirie marble*. Its colour is pale blood-red, light flesh-red, and reddish-white; these colours are often seen in one and the same piece: the darker shades generally as spots and waved striae. What renders this marble particularly curious is the hornblende, and the other green substance which it contains disseminated, and part of which appears to belong to that species of the hornblende family, which is now generally called fahlite; the lighter coloured particles have been considered as corundum. It is mixed in different proportions with the marble, so as to produce pale blackish-green, dark asparagus-green, and a colour approaching to leek-green. Also particles of calcareous spar are seen intermixed with this substance; as also small rounded quartz particles of a bright red colour, and some mica in plates. Some of its varieties have the appearance of granite.

Beside this, professor Jameson mentions a white marble of the same kind, found with the one just mentioned; its colour is white, or very light blue; it contains scales of mica and crystals of hornblende, which latter, when minutely diffused, give the marble a green or yellowish-green colour, and when very intimately combined with the mass, form beautiful yellowish-green spots.

Another interesting variety of compact marble, is that of Iona, described by count Bournon. It is of a fine dull white, and has at first sight the appearance of pure compact feldspar. It is an intimate mixture of tremolite and pure compact carbonat of lime; sometimes with yellowish or greenish-yellow spots, owing to a less intimate admixture of a steatitic substance. It occurs in magnesian rocks, sometimes alternating with clayey and slaty steatite or magnesian slate.

A dark coloured shell marble occurs in the limestone quarries of the parish of Cummertrees in the county of Dumfries,

M A R B L E.

Dumfries, and large blocks of it (according to the anonymous describer of that parish) have been worked up for chimneys and hearths, some of which have been sent to London. The shells and other petrified bodies with which it is mixed, greatly add to its variety and beauty, as the whole receives a very fine polish.

IRISH MARBLES.

Ireland also has its valuable marbles, and quarries of them are wrought in various parts.

The variety best known in England is the *Kilkenny marble*, with black ground, more or less varied with white marks produced by petrifications. This marble contains a great variety of impressions of madrepores, of bivalve and turbinate shells: mytilites, turbinites, peccinities, tellinites, tubiporites, nautilites, and ammonites may be distinguished. The spar which occupies the place of the shells, sometimes assumes a greenish-yellow colour; in some places there are spots, though rarely, that reflect iridescent colours; and sometimes martial pyrites is imbedded in the marble. A kind of flaw sometimes appears in the stone, which, from its irregularly indented figure, is styled by the workmen a *skull*, as it resembles the sutures of a cranium.

The quarry of this marble, of which Mr. Tighe has given a full account, is called the black quarry: it is situated in the limestone district of Kilkenny, half a mile south of the town, near the right bank of the river Nore. The strata of marble, each of which is known by its particular appellation, succeeded in this order:

	Feet.	Inches thick.
Rock bed, about	-	4 0
Thin bed	-	1 4
Silver bed, from	-	1 6 to 2 feet.
Bad bed	-	2 0
Halfmoon bed	-	2 6
Bottom bed	-	3 0
Lower thin bed	-	1 6
Black bed	-	1 8
Griddle bed	-	2 0

The halfmoon and the bottom bed are reckoned among the best: the former is so called from the number of impressions of bivalve shells which it contains; the sections of the spaces they occupied, now filled with white spar, being more or less lunated: the black bed and the silver bed are both esteemed. The marble which approaches nearest to black is most valued at Kilkenny. The white marks on the polished stone, it is said, appear more strongly, or increase, by long exposure to the air.

This marble, from experiments mentioned by Mr. Tighe, may be considered as consisting of 97 *per cent.* mild calx, two *per cent.* carbon, and one *per cent.* magnesia and iron, of which the former is in the largest proportion.

Some coarse work of Kilkenny marble is finished at the quarry; a few of the blocks are split in the town by hand saws, where a little of the polished work is also done, and tomb-stones are cut, which are raised from a different quarry. But the principal work is done at the marble mill, which is on the left bank of the river, near two miles from Kilkenny.

The importation of the marble into England and Scotland has been hitherto prevented by a duty of two shillings the cubic foot; what is exported, therefore, is in the rude block. Tighe's Survey.

The quantity exported is about fifty tons annually. The marble sent to Dublin is conveyed on cars as far as Leighlin bridge, where it is embarked on the Barrow; that which

is exported is usually sent to Waterford, and goes by land, at least as far as Thomastown. The blocks exported are consigned chiefly to Liverpool and Glasgow. Wakefield's Ireland.

Black marble, exceedingly fine, has been raised at Crayleath, in the county of Down. It is susceptible of a very high polish, and, if well chosen, is free from those large white spots which are supposed to disfigure some of the Kilkenny marble. Dubourdiou's Survey.

In the county of Waterford different kinds of marble are discovered, as at Tureen, a fine variegated sort, composed of chocolate colour, white, yellow, and blue, blended into various shades and figures, which takes a good polish. A black marble, without any mixture of white, has been found near Kilcrump, in the parish of Whitechurch, of the same county; as also a grey marble beautifully clouded with white, spotted like some kinds of shagreen, and susceptible of a good polish.

At Loughlougher, in the county of Tipperary, a fine purple marble is found, which, when polished, looks exceedingly beautiful. Smith.

There are several fine variegated marbles in the county of Cork; Smith describes one with purplish ground, and white veins and spots, found at Churchtown; a blueish and white variegated marble, from the same place, with which, and a black variety, like that of Kilkenny, the chancel of the parish church is floored; several fine ash-coloured varieties of marble, as that of Castle Hyde, &c.

The county of Kerry affords several variegated marbles, such as that found near Tralee, not unlike the Kilkenny marble, except that the white spots are much larger, and the colour of the mass is not of so deep a black, but inclining more to the blue: it takes a fine polish, and may be raised in blocks large enough for tables, chimney-pieces, &c. Marble of various colours is found in the same county, in the islands near Dunkerron, in the river Kenmare. Some is black and white, others are purple and white, intermixed with yellow spots, and some beautiful specimens have been seen of a purple colour veined with dark green, resembling the veins in blood-stone. Sir William Petty had several quarries opened in these islands in his time, in order to carry on a marble manufactory; but they are now worked chiefly for the making of lime.

FRENCH MARBLES.

Brard has given a very complete account of the numerous varieties of marble found in France, of which the following is an abstract:

Department of the Arriège: the black marble of Moulis, said to have been known to the ancients. Purple breccia marble, from Seix, similar to the Italian purple breccia. There are several more fine varieties of marble found in this department, especially in the mountains called Du Cos.

Department of the Aude: the variety called *marbre de Languedoc*, or *de Sainte Beaulme*; it is of a fiery red, with white and grey zones, formed by madrepores. The eight columns which adorn the new triumphal arch, in the Caroufel at Paris, are of this marble, which was formerly only employed for the decoration of the royal palaces. The quarries are at Sainte Beaulme. The neighbourhood of Narbonne furnishes several valuable marbles, such as that improperly called *marbre de Languedoc*, which is white mixed with blueish-grey; a shell marble of an intensely black colour, with white belemnites; a purple marble with yellow spots, &c. This department is particularly rich in marbles.

Department

MARBLE.

Department of the Mouths of the Rhone: among the beautiful varieties of marble with which this department abounds are, the breccia marble of Marseille, called *brèche de Memphis*; it is reddish, and contains small white, grey, and brown fragments; a marble mixed of white, red, and yellow, known in the country by the name of *marbre de Sainte Beaume*, but very distinct from the marble of the department of l'Aude, to which this name properly belongs.

Department of Calvados: a marble of a dirty red, with large, grey, or white veins, composed of madrepores, called *marbre de Caen*, from the place where it is quarried; tables made of it are very commonly seen in the coffee-houses, &c. of Paris.

Department of the Côte d'Or: besides several spotted and breccia marbles, there are found in this department two varieties of lumachella, the one of a reddish-yellow, the other of a grey colour, both of which are known in commerce under the name of *lumachelles de Bourgogne*.

Department of the Hérault: one of the most esteemed French varieties of marble is that called *griotte*. Its colour is a deep brown, with blood-red oval spots, produced by shells. This marble has obtained its name from its brownish colour, being similar to that of a variety of cherries, likewise called *griotte*; but it also sometimes contains large white veins, which are situated in a transversal direction to the other spots, and which, as destroying the harmony of the other tints, are considered as a defect. The lapidaries dignify the variety which is destitute of these white veins with the epithet *Italian*; but the fact is, that both varieties occur in the department of the Hérault, and that neither of them is found in Italy. Some of the ornaments of the triumphal arch of the Caroussel are made of *griotte*; which is now much employed in the decoration of public monuments, and of splendid furniture. It is sold at about 200 francs the cubic foot. Several other varieties of marble are found in the same department, and used at Montpellier and in other neighbouring places.

Department of the Isère: a light grey marble, with fragments of a lively rose-red of different shades, and with spots of a chocolate-brown colour, from Ténin in Dauphiné. This fine marble takes a good polish.

Department of Jemappes: the madreporic marble of Mons, called *petit gris*, or *petit granit* by lapidaries; its colour is blackish-grey, dotted with grey-coloured fragments of madrepores. There are many more varieties of marble in this department, but most of them not employed in commerce.

Department of Maine and Loire: a grey and white marble veined with red, improperly called peach-blossom marble.—Grey, with white veins, known by the name of marble of Angers.

Department of Montblanc: a shining white marble, with grey veins, at Pons-de-la-Bride; being mixed with siliceous earth it has the property of giving out sparks with the steel; it is also much harder and more solid than the common marbles, and its specific gravity is greater. The Romans have employed it for the construction of several of their monuments. A breccia marble, called *brèche de Tarentaise*: it consists of a purple base, with small fragments of white, yellow, and sometimes blackish marbles. This marble, which is found at La Villette, above Moutier, is much esteemed, both on account of its fine colour, and the superior polish it takes. Also, a yellow breccia marble, not unlike some antique varieties, is found in this department.

Department of the North: a white and reddish-brown

marble, with white, ash-grey, and blue veins, called *marbre de Rance*, from the place in Hainaut, where it is found. It is esteemed on account of its beauty, and as an article of commerce. The black marble of Barbançon, with white veins, the grey variety with black spots, and white and aurora red veins from Clermont, the breccia marbles of Deulers, and Estroing-la-Rouillie, are also among the many valuable varieties furnished by this department.

Department of the Ourthe: the grey and white variety with blood-red spots, called *marbre de Hon*, is well known. It comes from the neighbourhood of Liege, and is made use of for tables, chimney-pieces, vases, &c.

Department of the Straits of Calais: a yellowish-brown marble, with white, grey, and yellowish-red veins, has been lately discovered at Boulogne, and employed for the construction of the column placed there in commemoration of the victories of the French emperor, whence it has obtained the name of *marbre Napoléon*. Its structure is lamellar in some places, and compact in others. It takes a good polish, and, what adds much to its value, it may be procured in very large blocks, which, though solid, are of very moderate weight: the cubic foot weighing about 180 pounds. There are several other varieties of marble furnished by this department, such as the brocatello of Boulogne, the marbles of Stingal, Lingou, &c.

Departments of the Pyrenees: the marble of Bayonne in the Lower Pyrenees, (called there *marbre vierge*, on account of its whiteness) is rather less fine-grained than Carrara marble. It is used in those parts for purposes of sculpture, but has the defect of turning yellow and spotted in a short space of time. More generally known is the *marble of Campan* in the High Pyrenees; this is a mixture of limestone and a talcose substance, which latter forms the entangled veins observable on its surface. There are three varieties of Campan, which, however, are often united in the same piece; the first, called *green Campan*, is of a very pale sea-green colour, and exhibits on its surface lines of a much deeper green, and forming a kind of network; the second, called *Isabel Campan*, is of a delicate rose colour, and, like the first, furnished with undulated veins of green talc; the third variety, the *red Campan*, is of a deep red colour, with veins of a still deeper red, and in some measure resembles some parts of the *griotte*. In order to form a correct idea of the Campan marble, properly speaking, we must imagine that these three varieties are united, so as to form large stripes of from a few inches, to two, three, or even six feet wide, which produce a very grand and pleasing effect when viewed in large masses. Where, therefore, the Campan marble can be employed in the large way, it may be looked upon as the most beautiful and splendid of all marbles. It should not, however, be exposed to the weather, since, by so doing, the talcose substance exfoliates, and leaves hollow places, which render its surface uneven and rough; but it answers extremely well in the interior of buildings, for chimney-pieces, slabs for tables, &c. There are immense quarries of this valuable marble at Campan, near Bagnère, in the High Pyrenees. The marble of Sarencolin, in the High Pyrenees (in the ci-devant Gascogne) exhibits on its surface large straight zones and angular spots of a yellow or blood-red colour, so that at first view it bears some resemblance to the marble called Sicilian. This is commonly known by the name of *Sarencolin* or *Sarancolin*; that of superior beauty has become scarce, and it is even said that the quarry which yielded the most perfect sort is entirely exhausted. The marble vulgarly called *brèche Caroline* appears to be nothing but a modification of the Sarencolin. The variety of marble called *marbre d'Antin*, has a white ground, and exhibits at its surface fire-red veins,

which

M A R B L E.

which sometimes produce very pleasing appearances. It is found at Verey, in the High Pyrenees. According to M. de Cambry it derives its name from the Celtic words *an tin* (of fire) or fire marble. In the High Pyrenees a most beautiful breccia is likewise found, the mass of which is of a light orange colour, containing small fragments of a brilliant whiteness. It takes an excellent polish, and may be manufactured into vases, tablets, &c. The breccia, called *brèche des Pyrenées*, is likewise held in great esteem; its base is brownish-red, and exhibits black, grey, and red middle-sized spots. It admits of a good polish. Besides those here enumerated, a number of other marbles are met with in the Pyrenees, than which no chain of mountains is richer in fine varieties.

Department of the Sambre and Meuse: the colour of the marble of Dinan is a fine black, but perhaps inferior in point of intensity to that of the antique black marble. It is used in sculpture: the arabesques in relief which ornament the church of St. Vaudrin at Mons, are made of it. There are two other black marbles found in this department, *viz.* that of Theux and that of Namur; the former, which is sprinkled with grey dots, is wrought with facility, and takes a very good polish, but emits a slightly sulphureous odour when rubbed or struck with a hard body; the latter, which often inclines to greyish-black, and is traversed by grey veins, is exported to Holland in square slabs, and constitutes a valuable article of commerce. All these black marbles are in great request for the flooring of churches, for tomb-stones, &c. The grey marble of Sainte Anne sprinkled with white spots, the remains of madreporæ, has been much used at Paris for tops of commodes, chimney-pieces, tables, &c.; but ever since the introduction of the unlightly marble from Jemappes, called *petit granit*, it has greatly sunk in estimation. The breccia marble of Vaulfort, between Dinan and Givet, also known by the name of *brèche de Dourlais*, has a reddish base with black, grey, and white spots; the pillars in the church of Saint Roque are covered with large slabs of this marble, which is susceptible of a good polish.

Specimens of the preceding varieties, and of the following Batavian marbles, are in the star of the rotunda before the library of the Central School (*ci-devant* palace of the governors of the Netherlands) at Brussels: marble of Agimont, near Namur; brownish-red mixed with grey, traversed by thick white veins.—Of Avennes-le-Seigne near Valenciennes; a white statuary marble, easily to be wrought, and becoming harder when exposed to the air.—Of Bourtombe; pale blue and reddish, with large white clouds.—Of Bray, near Roecule, dep. of Jemappes; deep grey, mixed with white.—Of Clermont, near Valcourt, Sambre and Meuse; pale grey, with large white spots.—Of Devignes, pale grey, shaded with deep grey, and marked with some white spots.—Of Dourlaïpe; a calcareous breccia with reddish-grey base, incrustated with grey fragments of different shades and sizes.—Of Eétrée, near Namur; a mixture of blueish-grey and pale grey, with whitish veins.—Of Franchimont near Florenne, Sambre and Meuse; pale red and pale blue, with white veins.—Of Fiery-le-petit, between Mons and Namur; white, with yellow and grey granular spots.—Of Gerfontaine, pale red shaded with blue, and traversed by large white veins.—Of Goghenée near Florenne, Sambre and Meuse; pale reddish-grey, waved with red in equal portions.—Of Groïghoux; dark grey, shaded with pale grey, with small white veins.—Of Haire, near Charleroy; pale blue and pale red, in clouds, with large white spots.—Of Lorraine; blueish-grey, a little veined with grey and white.—Of Limburg; brown, with white granular spots, appearing

like small belemnites.—Of Mouchène; greyish and white blended, with natural fissures.—Of Ourdin near Valenciennes; a white marble for statues and architectural ornaments.—Of Pegagne; blueish-grey, with large white spots.—Of Rancé; near Beaumont, dep. of Jemappes; reddish with various veins; used for chimney-pieces.—Of St. Renir, near Luxembourg; red, with brown, green, and blue veins, being one of the most beautiful marbles in Europe. It sometimes contains Mytili and other shells.—Of Renly; red and grey in large clouds, with white veins and spots.—Of Royalles; grey shaded, with white veins.—Of Roy-Soire, Sambre and Meuse; pale grey, with white zigzag stripes.—Of Solré; greyish-blue, with many white veins. Another variety from the same place, of a blueish-grey base, with disseminated small white shells.—Of Somme; grey shaded, with some white veins; with natural fissures.—Of Strée, near Thuin, Jemappes; grey veined, with white spots.—Of Thuillé, near Thuin; dark grey, with white veins, and fragments of shells.—Of Vaufart; pale blue, shaded pale red, with white stripes.—Of Zoude-Bart; dark grey with small clouds, mixed with grey and white.

Department of the Lower Seine: several varieties of yellow marbles, streaked with darker yellow, and exhibiting black dendrites, are found at St. Etienne, near Rouen: they are capable of a good polish, and M. Tory has invented an economical mode of polishing them.

Department of the Seine and Marne: an elegant marble called *Chateau-London*, of a very pale yellow, containing small inconspicuous shells and white translucent veins, has but lately been discovered in this department. The beautiful bridge of Namours is constructed of it.

Department of the Var: the highly esteemed marble called *Portor*, on account of the brilliant yellow veins in its deep black ground; the most beautiful variety comes from St. Maximin.

Department of the Vosges: an excellent quarry exists near Framont, in the mountain called the Mathiskopf, in which the marbles are disposed in horizontal beds; their principal colours are white, penetrated by red or black, and grey.

Department of the Po: a white statuary marble, of a finer grey than that of Carrara, is found at Ponté, near Turin; of this marble are constructed the mausoleums of the kings of Sardinia in the vaults of the church de la Supergue, near Turin.—*Verde di Suza* is a green and white marble, resembling the verde antico; it is found at Suza, in Piedmont.—*Marmo di Gassino*, called so from the place near Turin where it is found, is light grey spotted by shells which are easily detached from the mass; beautiful columns have been made of it.

The territory of GENOA furnishes several beautiful varieties of marble, the most remarkable of which is the *polzevera di Genoa*, called also in French *vert d'Egypte* and *vert de mer*. This marble is a mixture of granular limestone, with a talcose and serpentine substance disposed in veins; but sometimes these latter substances constitute by far the greater part of the whole, while the white granular limestone appears only here and there in veins and patches. It is sometimes mixed with a reddish substance. This marble was formerly much employed in Italy, France, and England for chimney-pieces, &c.; but owing to its sombre appearance is come into disuse.

CORSICA possesses, among other varieties, a good statuary marble of a fine and close grain, and pure milky whiteness, quarried at Ornofrio; it is comparable to that of Carrara.—Also a grey marble (*bardiglio*), a cipolin, and

MARBLE.

and some other varieties occur in Corsica. The island of Elba has immense quarries of a white marble with blackish-green veins.

Among the innumerable varieties of ITALIAN MARBLES the following deserve more particular notice.

The *rossio* is a white marble found at Padua; it is used for architectural purposes, but is inferior in quality to those of Carrara and Genoa.—The white marble of St. Julien, at Pisa, is of a finer grain than that of Carrara, but takes no good polish; the cathedral and the celebrated tower of Pisa are constructed of this marble.—The Bianco marble is white with a slight tinge of grey; it is quarried at St. Gregoire, Magurega, &c. and chiefly employed for altars and tombs. Near Mergozzo the white saline marble with grey veins is found, with which the cathedral of Milan is built.—A white marble sprinkled with little spots and dots of blood red, occurs at Luni, on the coast of Tuscany.—Another white variety variegated with red and yellow spots and veins, is found in different parts of the Venetian territory.

The black marble of Bergamo is called *paragone* (derived from the black colour of touchstone); it is the most pure and intense tint, and susceptible of a fine polish.—The black marble of Como, in the Milanese, is also greatly esteemed on account of the intensity of its colour. Near the lake of Como and at Valerano, there are, likewise, quarries of excellent black marble, which has been employed in the cathedral of Sienna.

The *palacroso* of Piitoya is a black marble sprinkled with dots, which gives it the appearance of being covered with dust; there are beautiful slabs of it on the walls of the famous chappel of San Lorenzo.—A most beautiful white marble with black spots from the Lago Maggiore, which has been employed for decorating the interior of many churches in the Milanese.

The Margorre marble, found in several parts of the Milanese, is blueish veined with brown. Part of the dome of the cathedral of Milan is built of this marble.

The green marble of Florence owes its colour to a copious admixture of steatite. Another green marble, called *verde di Prado*, is found near the little town of Prado, in Tuscany; it is marked with spots of a deeper green than the rest, and passing even into blackish-blue.

The beautiful *Sienna marble*, or *brocatello di Siena*, has a yellow colour resembling the yolk of an egg, and disposed in large irregular spots, surrounded with veins of blueish-red, passing sometimes into purple. It is by no means uncommon in this country. At Montarenti, two leagues from Sienna, another yellow marble is found, which is traversed by black and purplish-black veins. This is frequently employed throughout Italy.—The marble of Brema is yellow with white spots.

The *mandelato* of the Italians is a light red marble, with yellowish-white spots, found at Lugezzana, in the Veronese. Another variety, bearing the same name, occurs at Preosa. They are both employed for columns and various other works.—The red marble of Verona is of a red, rather inclining to yellow, or hyacinth; that of a brighter red, and which contains some ammonites, is highly esteemed, and the tomb of Petrarca, at Arquois, recently engraved by Faujas, is of this variety; the other variety, of a dull red, has been employed by the Romans, as may be seen, for instance, in the vast amphitheatre of Verona, which is entirely built with it. Another marble is found near Verona, which Faujas calls *offious marble*, because he supposes the large white spots in the reddish and greenish paste to

be owing to the remains of bones, of which they still retain the figure. Very fine columns have been made of this marble.

Another Italian shell-marble is the *occhio di pavone*, the shells of which form large orbicular spots, red, white, and blueish. According to Da Costa, the peacock's eye is of a bright cinnabar colour, with spots and veins of milk-white spar; many of the spots, forming circles about the size of a sixpence, are filled with a red ground, and from an imaginary resemblance have conferred the name. (P. 213.)—A madreporic marble, known under the name of *pietra stellaria*, much employed in Italy, is entirely composed of star madreporas, converted into a grey and white substance, and is susceptible of an excellent polish.

Among the Italian breccia marbles are: the violet, called in France *brèche d'Italie*, the ground of which is reddish-brown, veined white; it is a beautiful marble, but requires much care, since it becomes soon spotted by coming into contact with greasy substances. The village of Bretonico, in the Veronese, furnishes a splendid breccia marble, composed of yellow, steel-grey and rose-coloured spots. That of Bergamo consists of black and grey fragments, in a greenish cement.

Florence marble, also called *ruin marble*, is a calcareous marble; which see.

SICILY abounds in marbles. Baron Borch, in his Sicilian mineralogy, describes upwards of a hundred varieties, of which the following appear to be the most important.

The principal and most valuable marble of Sicily is that frequently called *Sicile*, or *Sicile antique*, and by English stonecutters *Sicilian jasper*; it is red, with large stripes like ribbons, white, red, and sometimes green, which here and there revolve, forming petty acute angles. At Bisachino a milk-white and an apple-green variety occur; both take a fine polish. Trapani presents a red marble with deeper red spots, and another with green spots: at the same place is found the variety called *bigio bianco*, being grey with white spots, another spotted with several colours; and one (called *pidocchiofo*), formed by the union of small red and yellow grains or spots.—That of Castronuovo is yellow spotted with red.—Taormina furnishes several varieties: red with black spots; red with white veins, and deeper red spots; greenish mixed with bright brown spots; purplish, with particular reflections. The marble of Santa Maria del Bosco is of a deep black with yellow veins, not unlike that called *Portor*. At Termini we find a greenish marble with white veins and red dots. Near Sciacca they quarry a bright green marble, waved with deeper green and yellow.

Among the Sicilian breccia marbles are those of Gallo, the one of a light grey colour, presenting elegant rose-coloured spots of several shades; and the other also grey, veined yellow, and exhibiting on its surface white translucent spots. The breccia marble of Monte Alcano is light grey, with round and rose-coloured spots. That of Taormina has a deep red ground, and presents at its surface yellow and greyish-white spots.

SPANISH MARBLES.

Spain rivals Italy in the abundance and beauty of its marbles. The vicinity of Valencia, Cadiz, Burgos, Grenada, Molina, Carthagen, offer a great number of them. A mountain entirely composed of beautiful marbles exists at the distance of three leagues from San Felipe; the Tagus takes its course partly through hills of marble that constitute its bed, and the Carpentine mountains are equally provided

MARBLE.

provided with them. Hence it is that the monuments of antiquity in Spain, those of the middle ages, and of modern times, are profusely decorated with indigenous marbles. The vault of the beautiful theatre of Toledo is supported by 350 marble columns. The mosque of Cordova, erected by caliph Abdoulrahman III., is ornamented with 1200 columns, most of which are of Spanish marble: among the ruins of ancient Merida (Augusta Emerita), which was built 28 years before Christ, fragments of the most valuable marbles are still discovered; and finally, the church of the Escorial, and the palace itself, are decorated with the most beautiful marbles, and the same may be said of the principal churches of Madrid.

The milk-white marble of Cordova is very fit for sculpture; it has a fine grain and takes a good polish. Near Filabres, three leagues from Almeria, in Grenada, there is a mountain of about a league in circumference, and 2000 feet in height, which is entirely composed of the purest white marble, capable of the finest polish. The rocks which surround the town of Molina, in New Castile, are composed of a white marble, which has been employed in the palace of the Alhambra, at Grenada. The white saline marble of Grenada is slightly tinged with red. Also the white marble of Badajoz has rather a reddish tint, but its grain is finer and closer than that of the preceding. A white variety with large grey spots, at La Mancha, in New Castile. A greyish marble is quarried at Toledo, and one, grey with white veins and spots, at Elvira.

The black marble of La Mancha is of a very intense colour, and susceptible of a high polish. Another of the same colour is found near Segovia, and a deep black variety with grey dots at Moron. Biscay furnishes a black marble veined with white, and another of greyish-black colour with yellow veins: this latter is often called *Spanish portor*, but it is much inferior in beauty to that from St. Maximin, in the department of the Var.

A beautiful deep red variety, with shining white and bright red spots and veins, called *red Seville marble*.—Flesh-coloured, veined with white, from Santiago; and an entire mountain of this kind near Antiguera.—A dull red marble, with black capillary veins, found in Meguera, in Valencia, is much employed in Spain for tables.—Near Molina there is an entire hill of a red, yellow, and white marble, with granular and brilliant fracture, like fugar.—The mountains of Guipuscoa furnish a red marble veined with grey, and closely resembling that of Serancolin: Patrin even conjectures that it may be of the same bed. At Cortegana, in Andalusia, a fawn-coloured variety powdered with grey.

The violet marble, spotted with bright yellow, from Tortosa, is much admired on account of its fine colours and the polish it takes.—A marble of a dull violet colour, like wine-lees, with orange-yellow angular spots, is found near Valencia; it is not susceptible of a high polish.—A green marble, resembling the verde antico, presents itself at Grenada.

Near Morvedro there is a hill of black marble, veined with white, which, towards the summit, gradually passes into a yellowish-blue and reddish breccia.—A beautiful breccia marble is found at Riela, in Arragon; it consists of angular fragments of a black marble imbedded in a reddish-yellow base.—The breccia of Old Castile is of a bright red, dotted with yellow and black, and incloses middle-sized fragments of a pale yellow, brick-red, deep brown, and blackish-grey: it is much employed at Paris.

One of the most celebrated Spanish marbles (which may be regarded as a shell-marble), is the *brocatello*; its chief

colour is claret-red, variegated with numerous small spots, and points of isabell-yellow, yellowish-grey, and a translucent white. All the greyish spots in this marble, when closely examined, prove to be fragments of shells, but the irregular yellow and red spots are not owing to remains of organic bodies. The name of brocatello is given to all those marbles that resemble gold cloth and embroidered silk stuffs of the same kind.

PORTUGUESE MARBLES.

Portugal appears to be poor in marbles; there are, however, several varieties mentioned by authors; such as that of Villa-viciosa, in Alentejo, spotted with grey, and (as Bowles has it) resembling the marble of Mount Atlas. The chain of mountains of Arrabeda, in Estremadura, likewise furnishes some esteemed marbles.—The marble of Troncao is pale yellow, with greyish veins, and contains also remains of marine bodies.

The church of Alfara is built with marble of Cintra, a village on a mountain seven leagues distant from Lisbon.

SWISS MARBLES.

The marbles of Switzerland, at least those which are objects of commerce, are not numerous; nor is there great variety of colours among those few that are found in its mountainous regions.

At Roche, near Aigle, in the canton (now department) of Lemane, is a quarry of a marble veined with red, white, grey, and black; it is wrought on the spot, and is almost the only sort used at Geneva, and all over the Pays de Vaud: polished slabs of it are sent as far as Lyons. It often presents pectinites and madreporites, which have assumed the nature and grain of marble, so that the shells seldom or never appear in their original form.

The localities of some other marbles, which we know to be Swiss, are not indicated by any writer on the mineralogy of Switzerland. There was formerly a marble mill at Bern, from which the finest varieties found in Switzerland were sent into France, Germany, and England; but this we suppose does no longer exist.

GERMAN MARBLES.

The marbles of Germany are very numerous, and many of them far more beautiful than those foreign kinds which its wealthier inhabitants are so eager to obtain. A great number of them are even left unnoticed in the writings of topographical authors of that extensive country.

Austria, so rich in mineral treasures, excels also in the number and variety of its marbles.

The most esteemed of those of Lower Austria are the marbles of Schottwien, of Lilienfeld, Seitenstättten, and the Kammerguth. That of Lilienfeld is of an intense black colour.

Those of Stiria (of Lambrecht, Röthelstein, Zell, Maria-trost, &c.) are of the first quality.

Carinthia has some fine white marbles, and also possesses the most beautiful of all known shell-marbles, viz. that of Bleyberg, called *fire-marble*, or *opalifcent lumachella*. The colour of the marble itself is not particularly striking; it is brownish-grey, shaded with a darker tint, which latter belongs to the fragments of shells of which the mass is chiefly composed. But what distinguishes this variety of shell-marble from all others, are the opalescent fragments of a species of nautilus, here and there disseminated in its mass: the tints which they reflect are red, green, and blue, of considerable intensity. This most esteemed of all varieties of lumachellas is seldom seen in large pieces. The

MARBLE.

greatest variety of boxes and other articles made of it, exists in the collections of Vienna.

In Carniola are found, among others, a flesh-coloured and grey marble, veined with white and blue; nearly the same as that called by the Italians *Marmo breccia antica grifata*.—A yellow and dark red variety, with shrub-like veins; the same with that improperly called *Diaspro di Sicilia a vene*.—A pudding-stone marble, with pale red base, including grey and whitish rounded pieces; the same as the *Marmo breccia catinata* of the Italians.—A flesh-red marble, traversed by some calcareous spar, and called by the neighbouring Italians *Palmone di Porta Santa*; this is the most common variety of marble in those parts.—A black marble occurring in beautiful perpendicular strata; it is used for architectural purposes.—A white marble, not unlike that of Carrara, but mixed with dirty spots; nor can it be quarried in large blocks. Hacquet mentions several white varieties in other parts of Carniola, equalling and even surpassing the Carrara marble in whiteness and delicacy of structure.

Of Bohemian marbles, the finest white variety is that of the circle of Königgrätz; and among the variegated we have those of Czelitz, Kottel, and Sternberg, in the circle of Kaurzim. But still finer are those in the circle of Beraun: thus we have at Telin a brown-red, at Hermanomierltiz a light blue, at St. Juan a red and yellow, and red and white variety; the marble of Kosors is black, with imbedded petrifications, belemnites, entomolithus paradoxus, &c. Also Karlstein and Dobrzichowitz of the same circle furnish fine varieties of marble. That of St. Juan only is found in small pieces; all the others occur in considerable beds.

Moravia, though less rich in marbles than Bohemia, still furnishes some very valuable kinds in those of Hostienitz, in the circle of Brünn, and of Niklasburg (which latter is a beautiful lumachella); not to mention several others, the quarries of which are not wrought.

In Franconia we have the rich quarries of Hoff, which, among others, yield a fine black marble, a curious liver-brown variety with red spots, a sea-green, blueish, and several kinds of red marble. The marbles of Bayreuth present a great diversity of colour and delineation, and are of a fine close grain. There is a manufactory of various articles in these marbles, at the house of correction, in the capital of the principality.

The Hartz mountains in Lower Saxony produce some good marbles. Those of Blankenburg have been deservedly praised, on account of the pleasing colours they exhibit; there are some of a beautiful black, with straight and orbicular white stripes; others of the same colour, and with green and white spots; others with red spots; grey varieties, with white, brown, and red spots; and numerous red marbles, variegated with white, brown, greenish, and other colours. Several of those with a black, grey, and brown ground, contain madrepores and corallites. There were marble mills at Blankenburg, but there is very little employment for them at present.

At Langenstein, near Halberstadt, they quarry a very fine marble, another of a light green colour, and two white ones, with large brownish-red and yellow spots, of a fine appearance.

NORWEGIAN MARBLES.

Several of them are mentioned by Pontoppidan in his History of Norway, but it is dubious whether the worthy prelate has been correctly informed in this particular. Indeed, according to Mr. Neergard, there is only one quarry

in Norway, viz. that of Gillebeck, seven leagues distant from Chrilliania; but as the marble which it furnishes is saturated with a great quantity of pyrites, it generally becomes decomposed in a few years. The great church of Frederick, at Copenhagen, which is unfinished, is built with this marble. Neergard has often seen some pretty tablets of it, which contained garnets and actinote.

SWEDISH MARBLES.

Only a few of these are mentioned by authors, such as that found in the province of Jemtland, which is black and white, and also of an unmixed black; that of Kolmorden, in the province of East Gothland, composed of white granular limestone and serpentine. Neergard has given us an account of the quarry of Fagernech, situate between the two little towns of Norkjöping and Nykiöping, and about thirty leagues from Stockholm. It belongs, at present, to Mr. Eberstein, and to baron Unger, who purchased it from count Gyllenberg for only 200,000 francs, on account of its bad condition. This marble, which is white, with veins of green talc, the fracture brilliant, began to be wrought about 150 years ago, in the reign of queen Christina. The space where it is found is about 2000 fathoms in length, but its breadth is inconsiderable. They make of it tombstones, slabs for tables, vases for butter, salt cellars, and mortars; and the sale of these different articles amounts annually to about 20,000 francs. There are magazines of it at Stockholm, at Gottenburg, at Carlscrona, and at Abo. The manufactory employs about twenty workmen, who receive each two livres ten sous daily; and its position is fine and well adapted for working, as it is near the Baltic sea.

In the parish of Pargos, near Abo, in Finland, a very fine white marble is said to occur.

RUSSIAN and SIBERIAN MARBLES.

The vast Russian empire may naturally be supposed to abound in marble quarries; they are found in the Finnic and Taurian mountains, on the Caucasus, in the Ural, the Altaic, Sajanic, Krasnojarsk, and Dauric mountains; in the northernmost parts of Siberia, on the sea of Ochotzk, at the Penhinsk bay, on Tshutkoinof, Kamtschatka, the Kurile and Aleutian islands. The following varieties are enumerated in Georgi's "Beschreibung des Russischen Reichs:—" white saline marble in the Olonsk mountains, near the lake Gish, where there is a quarry near Tisdowa; also on Novaga Semla. A greyish variety, with needles of shorl, in the Onega islands; and another of the same colour, with green spots, on the banks of the Onega. A greyish-white saline marble, containing much tremolite in fascicular and radiating acicular crystals, in the quarry of Tisdowa. White scaly marble is found in various parts of the Ural and Altaian mountains, in the Kirgeese Steppe, in Nertschinsk, &c. &c. Pearl-grey, glimmering, granular limestone on the Ui and Tagil of the Tobol; in the Siberian marble quarries. Blueish-grey granular marble, with copper green, on the banks of the Lower Tshustowaja. Grey-clouded marble, near the Pereguba of the Onega; in the marble quarries of Catherineburg, &c. Brown granular marble on the banks of the Irish, near Jempalat; near Tshittinsk, in Nertschinsk. Black saline marble, at Kexholm; a variety of the same colour, but considerable hardness, in the vale of Alushta, in Tauris. A blackish-green variety, resembling serpentine, on the banks of the Tshustowaja, at Severskoi Sawod, and in the Guberlinfcian Ural. A light green variety in Dauria, at Kiächta; and another of the same colour, with dark green spots, on Janfa, an island

MARBLE.

island of the lake Ladoga. Reddish faline marble at Olonez. Dark red marble in Klimezkoi, one of the Onega islands, also in the Ural of Catherineburg. A variety of a light red colour, on the Argun of Dauria. Red faline marble, with brown stripes, near the Ui of Tobol, at Atagul, where it is quarried in large blocks. Yellow faline marble in the northern Ural, in the bay of Caria, near the Isel of Tobol, on the banks of the Irtish, at Jamusheva. A greyish-yellow variety, with dendriticæ, near the lake Ilmen. Dark and light red faline marble, with white veins, in the Oloneski quarries. Blackish-brown, with white veins, on the banks of the Onega. White marble, with black veins, on the banks of the Donez, at Bachmut. A grey variety, with white veins, on those of the Ik, at Wofnesenskoi Sawod. Greyish, with red veins, on those of the Tura, at Turinskoi Sawod. Red, with white veins, also dark green striped marble, in the Ural of Catherineburg, &c. White marble, with veins of white calcareous spar, and thorn-like spots, at Catherineburg. Blackish-grey marble, with veins of quartz, near the Loktewka, in Kolywan, and the Kokbukta of the Upper Irtish. A blackish-blue variety, with white veins of spar, at Nertshinskoi Sawod. Black faline marble, with brown stripes, at Tiwdewa, in Olonez. Marble, with stripes of various colours, in the mountains of Kolywan, the Ural, and Kirgeese mountains. Marble, with dots of various colours, in Olonezk, near the Ui of Tobolsk, &c. Spotted and flamed marble of various colours in Tiwdewa, on the banks of the Ladoga, in various parts of the Ural, &c. Black marble, with yellow spots, at Nertshinsk. Clouded uni-coloured and variegated marble, mostly with grey for its base, in the quarries of Finland and Catherineburg. This is quarried in very large blocks: it is very durable, and therefore employed for the construction of balconies, &c. in the imperial palaces. Scaly marble, of a white colour, mixed with red, in Finland, on the banks of the lake Gish, in the Ural. The same, of a grey colour, mixed with red, having dark spots, on an island of the lake Lishma, &c. A blue variety, mixed with red, on the northern banks of the lake Ladoga. Parti-coloured marble, a mixture of greenish, blackish, and white, at Kiächta, in the mountains of Dauria, &c.

Patrin, who during a residence of eight years examined the mineral treasures of those regions, has given the following account of the Siberian marbles. The Ural mountains furnish the finest and most variegated marbles. The greater part is taken from the neighbourhood of Katerinburg, where they are wrought, and from thence transported into Russia, and particularly to Petersburg. The late empress caused an immense palace to be built there for Orlof her favourite, which is entirely coated with these fine marbles, both inside and out. This empress built the church of Isaac with the same marbles, on a vast space, near the statue of Peter the Great. This church was not finished in 1787. Patrin saw there columns of very large dimensions, which seemed to be of a single block, of a white and blueish marble in large veins. Only this kind of marble was used in that church. The palace of Orlof has many varieties, which are distributed in compartments. Patrin found no white statuary marble in the Ural mountains; but in that part of the Altaian mountains which is traversed by the river Irtish, he in two places saw enormous rocks of marble, perfectly white and pure, from which large blocks might be hewn. The only use made of it is to convert it into lime for the service of the fortresses situated along the Irtish.

ASIA is probably very rich in marbles, but they are little known.

Shaw makes mention of a red marble with dendritic delineations from mount Sinai.

Of Syrian marbles we have no other account but that given in Ruffel's Natural History of Aleppo. They have at that city an inferior kind of yellow marble, which takes a tolerable polish, and is used for the ornamental parts of buildings, and for paving the court-yard. But a variety of other marbles is brought from parts more distant. From Damascus they receive a red marble; thence also and from Khillis, a coarse black sort; and from Antioch they procure various ancient fragments. The common Aleppo marble is brought to resemble the Damascus red by rubbing it with oil, and letting it stand some hours in an oven moderately heated.

Some Persian marbles are mentioned by Chardin, particularly a translucent white one. Mr. Morier, in his interesting "Journey through Persia, &c." just published, mentions the latter under the name of marble of Tabriz. The tomb of Hafitz, the celebrated Persian poet, is constructed with this beautiful substance; and the wainscoting of the principal room of the Haft-ten, near Shiraz, is likewise of Tabriz marble: one of the largest slabs is nine feet in length and five feet in breadth. Its colours are described, by this author, as a combination of light greens, with here and there veins of red and sometimes blue; he adds that it is not procured near the city of Tabriz, or taken from a quarry, but that it is said to be rather a petrification found in large quantities, and in immense blocks, on the borders of the lake Shahee, near the town of Meraugheh. We should take this substance to be a variety of calcareous alabastrer, were not the size of the pieces above-mentioned against this supposition.

The marbles of Hindoostan are unknown to us, and the same may be said of those of Siam and China: we are told that in the latter the streets of some towns are paved with marbles of all colours, and most public buildings, bridges, and monuments are constructed of it. Mention is made by authors of a quarry of white marble in the neighbourhood of Pekin. Labouliere speaks of a quarry of a beautifully white marble near the capital of Siam.

Some of the antique AFRICAN MARBLES have been mentioned in their proper place. A slate-blue variety (according to Brongniart) is still found at Sitifi in Mauritania; it is called *turchino*, or *marbre bleu turquin*, on account of its colour, which Tondi has found to be owing to the amphibole by which the marble is penetrated.

AMERICA.

There are many curious varieties of marble in North America. The chief quarries in the territories of the United States are at Stockbridge and Laneshorough, Massachusetts; in Vermont and Pennsylvania; in New York, and in Virginia: some of which are said to equal the finest kinds from Europe. At Marble town, near Hudson river, are quarries of fine black marble, spotted with white shells.

Marble of various qualities, (as professor Hall informs us,) has been found in many places on the west side of the green mountains in Vermont. A few years since a valuable quarry was discovered in Middleburg, a town situated on Otter Creek, eleven miles above Vergennes. The quarry forms one bank of the creek for several roods, and extends back into the side of a hill to a distance at present unknown. The stone lies in irregular strata, varying considerably in thickness, but all more or less inclined to the north-west. The marble is of different colours in different parts

MARBLE.

of the bed. On one side it is a pure white, and of a quality little, if at all, inferior to Italian white marble; but this seems to constitute but a small portion of the whole mass. The colour that predominates through most parts of the quarry is a grey of different intensities. The marble of both kinds is solid, compact, free from veins of quartz, and susceptible of an excellent polish. A mill of peculiar construction has been erected for the purpose of sawing the stone into slabs. It contains sixty-five saws, which are kept almost constantly in operation. During the years 1809 and 1810 these saws cut out 20,000 feet of slabs, and the sales of marble tables, sideboards, tomb-stones, &c. in the same period, amounted to about 11,000 dollars.

Part of the marbles of South America will probably be illustrated in Von Humboldt's travels in those interesting regions. Those of Chili, described in Molina's work on the natural history of that part of South America, are of various kinds. The varieties of a single colour hitherto discovered are, white statuary marbles, black, greenish, yellow, and grey. Two mountains, the one in the Cordelera of Copiapo, and the other in the marshes of Maule, entirely consist of marbles in zones of several colours; but in such strata as surround the mountains, from their base to the summit, with a symmetry that seems an artifice of nature. The variegated marbles are the grey with white, yellow, and blue veins; green, speckled with black; and yellow with black, brown, and green irregular spots. This latter, the quarry of which is at San-Fernando, the capital of the province of Colchagua, is in great esteem, because it is easily wrought, and hardens in the air. All the marbles of Chili are generally of a good quality, and all take a good polish. Persons who have had occasion to examine the Lower Andes, have assured Molina that those mountains abound in marbles of different qualities, and nearly of all colours. In the plains near the city of Coquimbo a white shell marble has been found, somewhat granular, three or four feet under the vegetable earth. The shells in it are more or less entire. The bed of this marble extends in length and breadth more than three miles; its thickness, generally about two feet, varies, and depends on the number of the beds, which are sometimes five, sometimes eight. These beds are almost always divided by very thin layers of sand. This stone increases in hardness in proportion to its depth: the first beds only present a coarse friable stone, of no use but to make lime; the following, although compact, easily yield to the iron instruments used to cut it, and raise it from the quarry; but in building acquire a sufficient hardness to resist any impression of the air or water. Molina, p. 57.

MARBLE, Artificial. The stucco, whereof they make statues, busts, basso-relieues, and other ornaments of architecture, ought to be marble pulverised, mixed in a certain proportion with plaster; the whole well sifted, worked up with water, and used like common plaster. See **STUCCO**.

There is also a kind of artificial marble made of the flaky selenites, or a transparent stone, resembling plaster; which becomes very hard, receives a tolerable polish, and may deceive a good eye. This kind of selenites resembles Muscovy talc.

There is another sort of artificial marble, formed by corrosive tincture, which penetrating into white marble to the depth of a line or more, imitate the various colours of other dearer marbles.

There is also a preparation of brimstone in imitation of marble.

To do this, you must provide yourself with a flat and smooth piece of marble: on this make a border or wall, to encompass either a square or oval table, which may be done either with wax or clay. Then having provided several sorts of colours, as white-lead, vermilion, lake, orpiment, masticot, smalt, Prussian blue, &c. melt on a slow fire some brimstone, in several glazed pipkins; put one particular sort of colour into each, and stir it well together; then having before oiled the marble all over within the wall, with one colour quickly drop spots upon it of larger and less size; after this, take another colour and do as before; and so on, till the stone is covered with spots of all the colours you design to use. When this is done, you are next to consider what colour the mass or ground of your table is to be: if of a grey colour, then take fine sifted ashes, and mix it up with melted brimstone; or if red, with English red ochre; if white, with white-lead; if black, with lamp or ivory black. Your brimstone for the ground must be pretty hot, that the coloured drops on the stone may unite and incorporate with it. When the ground is poured even all over, you are next, if judged necessary, to put a thin waincot board upon it: this must be done whilst the brimstone is hot, making also the board hot, which ought to be thoroughly dry, in order to cause the brimstone to stick the better to it. When the whole is cold, take it up, and polish it with a cloth and oil, and it will look very beautiful. Smith's Laboratory, p. 248.

MARBLE, Colouring of. The colouring of marbles is a nice art, and in order to succeed in it, the pieces of marble, on which the experiments are tried, must be well polished, and clear from the least spot or vein. The harder the marble is, the better it will bear the heat necessary in the operation: therefore alabaster, and the common soft white marble, are very improper to perform these operations upon.

Heat is always necessary for the opening of the pores of the marble, so as to render it fit to receive the colours; but the marble must never be made red-hot, for then the texture of the marble itself is injured, and the colours are burnt, and lose their beauty. Too small a degree of heat is as bad as too great: for, in this case, though the marble receives the colour, it will not be fixed in it, nor strike deep enough. Some colours will strike, even cold; but they are never so well sunk in as when a just degree of heat is used. The proper degree is that which, without making the marble red, will make the liquor boil upon its surface. The menstruums used to strike in the colours must be varied according to the nature of the colour to be used. A lixivium made with horse's or dog's urine, with four parts quick-lime, and one part pot-ashes, is excellent for some colours; common ley of wood-ashes does very well for others; for some, spirit of wine is best; and finally, for others, only liquors, or common white wine.

The colours which have been found to succeed best with the peculiar menstruums are these: stone-blue dissolved in six times the quantity of spirit of wine, or of the urinous lixivium; and that colour which the painters call litmus, dissolved in common ley of wood-ashes. An extract of saffron, and that colour made of buckthorn berries, and called by the painters sap-green, both succeed, well dissolved in urine and quick-lime, and tolerably well in spirit of wine. Vermilion, and a fine powder of cochineal, succeed also very well in the same liquors. Dragon's blood succeeds very well in spirit of wine, as does also a tincture of logwood in the same spirit. Alkanet-root gives a fine colour, but the only menstruum to be used for this is oil of turpentine; for
neither

neither spirit of wine, nor any lixivium, will do with it. There is another kind of *sanguis draconis*, called dragon's blood in tears, which, mixed with urine alone, gives a very elegant colour. Phil. Transf. N^o 268, or Abridg. vol. iv. part ii. p. 205.

Beside these mixtures of colours and menstruums, there are some colours which are to be laid on dry and unmixed. These are dragon's blood of the purest kind, for a red; gamboge for a yellow; green wax for a green; common brimstone, pitch, and turpentine, for a brown colour. The marble for these experiments must be made considerably hot, and then the colours are to be rubbed on dry in the lump. Some of these colours, when once given, remain immutable; others are easily changed or destroyed. Thus the red colour given by dragon's blood, or by a decoction of logwood, will be wholly taken away by oil of tartar, and the polish of the marble not hurt by it.

A fine gold colour is given in the following manner: take crude sal ammoniac, vitriol, and verdigris, of each equal quantities: white vitriol succeeds best, and all must be thoroughly mixed in fine powder.

The staining of marble to all the degrees of red, or yellow, by solutions of dragon's blood or gamboge, may be done by reducing these gums to powder, and grinding them with the spirit of wine, in a glass mortar; but for smaller attempts, no method is so good as the mixing of a little of either of these powders with spirit of wine, in a silver spoon, and holding it over burning charcoal. By this means a fine tincture will be extracted, and with a pencil dipped in this, the finest traces may be made on the marble, while cold, which, on the heating of it afterwards, either on sand, or in a baker's oven, will all sink very deep, and remain perfectly distinct in the stone. It is very easy to make the ground-colour of the marble red or yellow by this means, and leave white veins in it. This is to be done by covering the places where the whiteness is to remain with some white paint, or even with two or three doubles only of paper, either of which will prevent the colour from penetrating in that part. All the degrees of red are to be given to marble by means of this gum alone; a slight tincture of it, without the assistance of heat to the marble, gives only a pale flesh-colour; but the stronger tinctures give it yet deeper; to this the assistance of heat adds yet greatly; and finally, the addition of a little pitch to the tincture gives it a tendency to blackness, or any degree of deep red that is desired.

A blue colour may be given also to marble by dissolving turnsol in a lixivium of lime and urine, or in the volatile spirit of urine; but this has always a tendency to purple, whether made by the one or the other of these ways. A better blue, and used in an easier manner, is furnished by the Canary turnsol, a substance well known among the dyers. This needs only to be dissolved in water, and drawn on the place with a pencil: this penetrates very deep into the marble, and the colour may be increased by drawing the pencil, wetted afresh, several times over the same lines. This colour is subject to spread and diffuse itself irregularly; but it may be kept in regular bounds, by circumscribing its lines with beds of wax, or any other such substance. It is to be observed, that this colour should always be laid on cold, and no heat given even afterwards to the marble; and one great advantage of this colour is, that it is therefore easily added to marbles already stained with any other colours, and it is a very beautiful tinge, and lasts a long time. Mem. Acad. Par. 1732.

This art has in several people's hands been a very lucrative secret, though there is scarcely any thing in it that has not at one time or other been published.

Kircher has the honour of being one of the first who published any thing practicable about it. This author meeting with stones in some cabinets supposed to be natural, but having figures too nice and particular to be supposed to be nature's making, and these not only on the surface, but sunk through the whole body of the stones, was at the pains of finding out the artist who did the business; and on his refusing to part with the secret on any terms, this author, with Albert Gunter, a Saxon, endeavoured to find it out; in which they succeeded at length very well. Their method is this: take aqua fortis and aqua regia of each one ounce, sal-ammoniac one ounce, spirit of wine two drachms, about twenty-six grains of gold, and two drachms of pure silver; let the silver be calcined and put into a phial, and pour upon it the aqua fortis; let this stand some time, then evaporate it, and the remainder will first appear of a blue, and afterwards of a black colour; then put the gold into another phial, pour the aqua regia upon it, and when it is dissolved, evaporate it as the former; then put the spirit of wine upon the sal-ammoniac, and let it be evaporated in the same manner. All the remainders, and many others made in the same manner from other metals dissolved in their proper acid menstrua, are to be kept separate and used with a pencil on the marble. These will penetrate without the least assistance of heat, and the figure being traced with a pencil on the marble, the several parts are to be touched over with the proper colours, and this renewed daily till the colours have penetrated to the desired depth into the stone. After this the mass may be cut into thin plates, and every one of them will have the figure exactly represented on both surfaces, the colours never spreading. The nicest method of applying these, or the other tinging substances, to marble that is to be wrought into any ornamental works, and where the back is not exposed to view, is to apply the colours behind, and renew them so often till the figure is sufficiently seen through the surface on the front, though it does not quite extend to it. This is the method that of all others brings the stone to a nearer resemblance of natural veins of this kind. The same author gives another method to colour marble by vitriol, bitumen, &c. forming a design of what you like upon paper, and laying the said design between two pieces of polished marble; then closing all the interstices with wax, you bury them for a month or two in a damp place. On taking them up, you will find that the design you painted on the paper has penetrated the marbles, and formed exactly the same design on them. Kircher's Mund. Subter. lib. viii. § 1. cap. 9.

Wallerius, in his Mineralogy, vol. ii. p. 128. recommends the last method of Kircher; and the first method is copied in the Phil. Transf., N^o 7.

The art was practised by Mr. Bird, a stone-cutter at Oxford, before the year 1666; but his method is not recorded. Mr. Robert Chambers, of Minching Hampton, in Gloucestershire, discovered and practised a method of colouring marble, which he kept a secret. Mr. Da Costa has published an account of experiments made on several pieces of marble stained by this artist. Phil. Transf. vol. li. art. 5. p. 30, &c.

Spots of oil stain white marble, so that they cannot be taken out. See STAINING of Stones.

MARBLE, *Polishing of*. The art of cutting and polishing marble was, of course, known to the ancients, whose mode of proceeding appears to have been nearly the same with that employed at present; except, perhaps, that they were unacquainted with those superior mechanical means which now greatly facilitate the labour, and diminish the expence of the articles thus produced. There are many celebrated manu-

factories of this kind generally called marble mills, on the continent, and also in Great Britain; but as the principle on which they proceed is nearly the same in all, it will suffice in this place to give the description of one or two of the latter. The following description, together with some preliminary observations, communicated by a person practically acquainted with this subject, relate to the manufactory of Messrs. Brown and Mawe at Derby.

An essential part of the art of polishing marble is the choice of substances by which the prominent parts are to be removed. The first substance should be the sharpest sand, so as to cut as fast as possible, and this is to be used till the surface becomes perfectly flat. After this the surface is rubbed with a finer sand, and frequently with a third. The next substance after the finest sand is emery of different degrees of fineness. This is followed by the red powder called tripoli, which owes its cutting quality to the oxyd of iron it contains. Common iron-stone powdered and levigated answers the purpose very well. This last substance gives a tolerably fine polish. This, however, is not deemed sufficient. The last polish is given with putty. After the first process, which merely takes away the inequalities of the surface, the sand employed for preparing it for the emery should be chosen of uniform quality. If it abounds with some particles harder than the rest, the surface will be liable to be scratched so deep as not to be removed by the emery. In order to get the sand of uniform quality, it should be levigated and washed. The hard particles, being generally of a different specific gravity to the rest, may by this means be separated. This method will be found much superior to that of sifting. The substance by which the sand is rubbed upon the marble is generally an iron plate, especially for the first process. A plate of an alloy of lead and tin is better for the succeeding processes, with the fine sand and emery. The rubbers used for the polishing, or last process, consists of coarse linen cloths, such as hop bagging, wedged tight into an iron plane. In all these processes, a constant supply of small quantities of water is absolutely necessary.

The sawing of marble is performed on the same principles as the first process of polishing. The saw is of soft iron, and is continually supplied with water and the sharpest sand. The sawing, as well as the polishing of small pieces, is performed by hand. The large articles, such as chimney-pieces and large slabs, are manufactured by means of machinery working by water or steam. We shall next give a description of this branch of manufacture in the large way, as carried on by Brown and Mawe at Derby, and in London, N^o 149 Strand, who have justly attained great celebrity as workers of spar and marble into different ornaments.

Fig. 1. Plate XXIII. Miscellany, is a side view of a mill for sawing and polishing slabs of marble; *fig. 2.* being a ground plan of the same, and marked with corresponding letters. A B C is a frame of wood, suspended by the upright frames of wood, D, E, F, G, from the beams H, H, H, H, so as to be capable of an oscillatory motion. Motion is given to this frame by the rod I communicating with the crank O K, which is turned by water or steam.

This frame, being put in motion, gives motion to the saw frames L, L, M, M, and to the polishing arms N, P, Q, which work on the pivot P, and are pushed backwards and forwards by the connecting iron rods *n, n*. The saws are iron plates shaped like a common saw, and fastened into oblong rings by means of pins. These rings are put upon the cross bars E, E, *b, b*, and the saws are stretched tight by the screws *s, s, s*, and C. R, R, S, S, are four upright posts

constituting a frame, in which are placed the blocks of marble to be sawn into slabs, which are at the same time to guide the frame of the saw. At each end of this frame there are a number of upright square bars of iron *i, i*, between which the saws pass which bars, act as conductors. The posts R, R, can be removed to a greater distance, so as to make the frame longer for receiving different sized blocks. The part T, to which the saw is attached on the moveable frame, slides upon the upright post A C. It is suspended by a rope, which goes over a pulley *c*, and is counterbalanced by the weight W. By this means the saw may be made to press upon its work with any degree of force. It will be evident that the moveable frame, from its pendulous motion, does not move in a straight line, but a curve. The sliding part T, therefore, serves to induce a rectilinear motion of the saw. The upright bars of iron *i, i*, and C, are of a size equal to or less than the thinnest slabs, so that the saws may be placed at different distances, according to the thickness of the slabs. In order to alter the saws for this purpose, nothing more is necessary than to loosen the screws *s, s*, &c. and shift the oblong rings which contain the saws.

The slabs of marble to be polished are laid upon the carriage *b*, so as to correspond with the rubber Q, which passes over it in the direction of its length. In order to extend the rubber to the other parts of the slab, the carriage, *b*, has a lateral motion, by means of four grooved wheels running upon the iron guiders let into the beams *g, g*. The endless screw *c*, in the main shaft, turns the wheel *r*. This gives motion to the lever *w*, *fig. 2*, by means of the crank *g*. The lever communicates with the crank *k*, and turns the wheel *l*, more or less of a revolution, according to the length of this crank, which can be altered at pleasure by shifting the temporary pin *e*. By this latter motion the wheel, *l*, works the ratch *v*, and gives the lateral motion to the carriage. By this means the whole of the surface is exposed to the action of the rubber. Round articles of spar, gypsum, and marble, are turned in the lathe with pointed instruments of hardened steel. The pieces to be turned are attached to a wooden chock by means of cement. The gypsum is very soft, and turns with great facility. The fluor spar and marble require the tool to be very hard, while the part to be turned requires a constant supply of water, which drops from a vessel above. After the articles are turned into the given shape, they are dressed with sand and emery, and afterwards polished with tripoli and putty.

Small specimens for collections of marbles are generally polished upon a lap, which runs in a lathe. These laps, however, ought to run with the axis perpendicular to the horizon, the face of the lap being truly flat and horizontal. The lap used for the first process should be of iron; the second of an alloy of lead and tin; and the third, which is for polishing, should be of iron with pitch. By means of some auxiliary machinery, a number of pieces might be polished in this way at once, which would save much manual labour. Small pieces of marble may also be polished on the large machine, by cementing them with plaster on the surface of a large slab. By being placed on the same level, the large rubber sweeps them all at once.

The marble mill in the neighbourhood of Kilkenny, in Ireland, mentioned under the article IRISH MARBLES, *supra*, and which was invented by alderman Collis, grandfather of the present proprietor, is remarkable for the simplicity of its structure, and for the powers it exerts. One wheel, ten feet diameter, with twelve floats or lades, gives motion, by a crank at one end of its axis, to a frame containing twelve saws, which do the work of about twenty men. By a

crank at the other end, it moves a frame of five polishers, which do the work of about ten men. At this end Mr. Collis has lately fitted a frame beneath the polishers, with eight saws, to the motion of which he has found the power of the machine fully equal. This mill may be fairly said to do the constant work of forty-two men daily. During the night the mill stopped, a constant attention being required to supply the saws with sand, and to attend the polishers. The saws are made of soft iron, and last about a week; they are constantly supplied with water and sand; the latter is taken out of the bed of the Nore, and washed till nothing remains, but very fine and pure siliceous particles. A saw cuts ten inches in a day, and twelve when the water is strong; it would require two men to do the same with a hand saw. The marble taken from the mill is first polished with a *cove-stone*, that is, a brown sand-stone imported from Chester, and which takes its name from being used in chimney coves. It is afterwards polished by a *bone-stone*, which is a piece of smooth nodule of the argillaceous iron ore, found in the hills between Kilkenny and Freshford. It receives the last polish in the mill with rags and putty. By means of this mill, the marble is so easily worked as to be sold at a very moderate price.

A great improvement in cutting marble and other stones, but particularly columns by machinery, was invented in Ireland by the late sir George Wright, bart., who procured a patent for it. By this a number of hollow columns can be cut from a solid block, each decreasing in size, so that nothing of the stone is lost, except what is converted into dust by the saw.

MARBLE Harbour, in *Geography*, a bay in the Mergui Archipelago, on the E. coast of Sullivan's island. N. lat. $10^{\circ} 58'$.

MARBLE Island, a small island of the Mergui Archipelago, at the entrance of Marble harbour.—Also, an island in Hudson's bay. N. lat. $62^{\circ} 35'$. W. long. $91^{\circ} 30'$.

MARbled, something veined, or clouded, resembling marble. Marbled paper is a paper stained with various clouds and shades, resembling, in some measure, the divers veins of marbles; the method of making which, see under **PAPER**.

MARbled China-ware, a name given by many to a species of porcelain or China-ware, which seems to be full of cemented flaws. It is called by the Chinese, who are very fond of it, *tsou-tchi*.

It is generally plain white, sometimes blue, and has exactly the appearance of a piece of China which had been first broken, and then had all the pieces cemented in their places again, and covered with the original varnish. The manner of preparing it is easy, and might be imitated with us. Instead of the common varnish of the china-ware, which is made of what they call oil of stone and oil of fern mixed together, they cover this with a simple thing made only of a sort of coarse agates, calcined to a white powder, and separated from the grosser parts by means of water, after long grinding in mortars. When the powder has been thus prepared, it is left moist, or in form of a sort of cream, with the last water that is suffered to remain in it, and this is used as the varnish. Our crystal would serve full as well as these coarse agates, and the method of preparation is perfectly easy. *Observ. sur les Couët. de l'Asie*.

The occasion of the singular appearance of this sort of porcelain is, that the varnish never spreads evenly, but runs into ridges and veins. These often run naturally into a sort of mosaic-work, which can scarcely be taken for the effect of chance. If the marbled China be desired blue, they first give

it a general coat of this colour, by dipping the vessel into a blue varnish; and when this is thoroughly dry, they add another coat of this agate-oil.

MARBLEHEAD, in *Geography*, a port of entry, and post-town of America, in Essex county, Massachusetts, containing one episcopal, and two congregational churches, and 5211 inhabitants. The harbour lies in front of the town S.E. extending from S.W. to N.E., about a mile and a half in length, and half a mile broad. A battery and citadel were erected here in 1795, for the defence of the place, by order of Congress. The bank-fishery employs the principal attention of the inhabitants, and more of this business is done here than in any other place in the state. The exports of the year 1794 amounted to 184,532 dollars. - Marblehead was incorporated in 1649, and lies 4 miles S.E. of Salem, and 19 N.E. of Boston. N. lat. $42^{\circ} 30'$. W. long. $69^{\circ} 49'$.

MARBLES, PLAYING, are mostly imported from Holland, where it is said they are made by breaking the stone alabaster, or other substance, into pieces, or chips of a suitable size; these are put into an iron mill which turns by water: there are several partitions with rasps within, cut float-ways, not with teeth, which turn constantly round with great swiftness; the friction against the rasps makes them round, and as they are formed they fall out of different holes, into which size or chance throws them. They are brought from Nuremberg to Rotterdam, down the Rhine, and from thence dispersed over Europe.

MARBLETOWN, in *Geography*, a township in Ulster county, New York, on the W. side of Hudson river, N.W. of Pultz, adjoining. It contains 2847 inhabitants.

MARBLING, the art or act of painting or disposing colours in such a manner, that they may represent marble. Thus we marble books, paper, wood, &c. See **PAPER**, and **Colouring, &c. of BONE**.

MARBLING of Books, among *Binders*, denotes the sprinkling over the cover of a book first with ink, and afterwards with weak aquafortis. See **BOOK-binding**.

They also marble books on the edges; but, in this marbling, there is no black used, but, in lieu thereof, red, blue, &c.

MARBŒUF, in *Geography*, a town of France, in the department of the Eure; 12 miles N. of Conches.

MARBOS, a town of France, in the department of the Ain; 8 miles N. of Bourg-en-Bresse.

MARBURG, a town of the duchy of Stiria, seated on the Drave, which had formerly counts of its own; 31 miles S. of Gratz. N. lat. $46^{\circ} 40'$. E. long. $15^{\circ} 37'$.

MARBURG, or *Marpurg*, a town and capital of Upper Hesse, on the W. side of the Lahn, defended by a castle, in which the landgraves of Hesse formerly resided. This town has an university, founded in 1527 by the landgrave Philip the Magnanimous, also an academy for classical literature, and three Protestant churches. About the beginning of the thirteenth century, this place was raised from a village to a town. In 1261 and 1319 it was wholly destroyed by fire. In 1759 it was garrisoned by French troops, who were soon after obliged to surrender themselves prisoners of war; 36 miles N. of Francfort-on-the-Maine. N. lat. $50^{\circ} 48'$. E. long. $8^{\circ} 48'$.

MARC, in *Biography*. See **MARCOSIANS**.

MARCA, **PETER DE**, a celebrated French prelate, was born at Gant, in the principality of Bearn, in the year 1594. Having laid a good foundation in classical learning and polite literature, he went through a course of philosophy under the Jesuits at Toulouse: after this he studied the law, and at the age of twenty-two was nominated by Lewis XIII. counsellor

in the sovereign council of Pau, in which, though he was the only Catholic in that court, he conducted himself with so much prudence, that he maintained perfect harmony with all his coadjutors, and was successful in bringing back several of the reformed into the bosom of the Catholic church. In the midst of other important engagements, he devoted much of his time to the study of theology and ecclesiastical antiquities. In 1639 he was called to Paris, and was honoured with the rank and dignity of counsellor of state. In the following year he published his "History of Bearn," which tended greatly to confirm the reputation that he had already acquired for learning and abilities. About this time M. Herlent published an artful defence of the Papal pretensions over the Gallican church, in the form of a satire on the policy of cardinal Richelieu, which, it pretended, aimed at the separation between the churches of Rome and France, similar to the schism produced by Henry VIII. in England; and the erection of a patriarchate in France in the person of the cardinal. To counteract the effects of this work, Richelieu employed the pen of M. de Marca, who, in 1641, published a piece entitled "De Concordia Sacerdotii et Imperii, sive, de Libertatibus Ecclesie Gallicae." This was a very learned, and generally esteemed excellent, vindication of the rights and liberties of the French church and state, and it was received with great applause by those Catholics, who, though steadily attached to the doctrines of the church of Rome, resisted the tyranny and injustice of its aspiring pontiffs: but in the court of Rome it excited much indignation against the author, of which he soon felt the effects. The king appointed him to a bishopric, which the cardinals, by certain manœuvres, prevented him from entering upon, till he had retracted or explained away every sentiment that had given offence at Rome, and by declaring his unreserved submission of what he had written, or might in future write, to the sovereign judgment of the holy apostolic see. Having by this servile conduct appeased the resentment of the papal court, he was ordained priest, and immediately afterwards consecrated bishop. This was in the year 1648, and in 1652, as a reward for other services, he was nominated archbishop of Toulouse, but, by a new opposition from the court of Rome, he was not translated till the year 1653. In 1658 he was made a minister of state, and followed the king to Lyons, after which he was appointed to preside over the states of Narbonne, upon the death of the archbishop. After Cardinal Mazarin had concluded a peace, he was sent to Rouffillon for the purpose of determining, with the commissioners of the king of Spain, the precise limits between France and Spain, according to the boundary line of the ancient geographers. Upon the death of the cardinal, in 1661, Marca was selected as one of the persons to preside over ecclesiastical affairs, and in the following year he was, in consequence of the resignation of cardinal de Retz, nominated to that dignity, but he did not live to enjoy, or even to take possession of this high office. He died about the sixty-eighth year of his age: he was a man of profound erudition, of a fine understanding, and of an extraordinary genius for business. He was a great politician, a good lawyer, a learned divine, and an able critic. He never scrupled to make his principles give way, if by so doing he could promote his own interests. A few months before his death he dictated to his secretary "A Treatise on the Infallibility of the Pope," with the express view of recommending himself to a cardinal's hat. The best edition of his celebrated work "De Concordia" was published after his death, in 1704, in which the concessions with which he had purchased the papal bull to obtain the prelacy, were, by his order, directed to

be omitted, and the work given in its original state. He was author of several other pieces, among which were "Marca Hispanica," containing a curious and valuable geographical and historical description of Catalonia, Rouffillon, and the neighbouring countries: "An Account of what passed in the Assemblies of the Bishops in 1653:" "Theological Treatises;" and two volumes of "Opuscula." Moreri.

MARCANTHUS, in *Botany*, is a genus of Loureiro's, so called by an unaccountable, though we presume accidental, mistake for *Macranthus*, since the derivation of its name being avowedly from μακρός, long, (which he erroneously writes μακρός,) and αἶθος, a flower; the genus being very remarkable for the great length of its flowers. Loureir. Cochinch. 460.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceae*, Linn. *Leguminosae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, tubular, coloured, downy, permanent, cloven into four, acute segments, the two lateral ones shorter. *Cor.* papilionaceous, very long, almost closed. Standard ovate, emarginate, connivent, longer than the calyx. Wings oblong, erect, thrice as long as the standard. Keel longer than the wings, with an acute, ascending point. *Stam.* Filaments ten, simple and nine-cleft, all linear-turbinate, acuminate and straight, four of them three times as thick as the rest; anthers of the thicker ones ovate, incumbent; of the others oblong and upright. *Pist.* Germen superior, oblong, cylindrical; style thread-shaped, hairy all over, the length of the stamens; stigma obtuse, roughish. *Peric.* Legume straight, nearly cylindrical, thick, pointed. *Seeds* numerous, nearly ovate.

Ess. Ch. Keel and wings very long. Legume thick, somewhat cylindrical.

1. *M. cochinchinensis*. Loureir. Dâu meò, of the natives.—A native of cultivated ground in Cochinchina.—The stem is herbaceous, long, round, twining, branched. Leaves ternate, ovate-rhomboid, hairy. *Stipulus* thread-shaped. Flowers white, with a calyx of the same colour, on many-flowered, axillary stalks. Legume esculent, although neither well tasted nor salubrious.

MARCAPATA, in *Geography*; a town of Peru, in the jurisdiction of Quisnicanchi.

MARCARIA, a town of Italy, in the department of the Mincio, on the Oglio; 14 miles S.W. of Mantua.

MARCASI, three small islands in the Pacific ocean, near the coast of Peru. S. lat. 11° 30'.

MARCASITE, in *Mineralogy*, *Arsenical Pyrites* of Kirwan. See ARSENIC.

MARCAY, in *Geography*, a town of France, in the department of the Vienne; 7 miles S. of Poitiers.

MARCEL, St., a town of France, in the department of the Ardèche; 24 miles S. of Privas.—Also, a town of France, in the department of the Mouths of the Rhône; 5 miles E. of Marseilles.—Also, a town of New Navarre; 130 miles S.W. of Casa Grande.

MARCELLIANISM, in *Ecclesiastical History*, the doctrines and opinions of the Marcellians, a sect of ancient heretics, towards the commencement of the third century, so called from Marcellus of Ancyra, their leader, who was accused of reviving the errors of Sabellius.

It is generally supposed that Marcellus, bishop of Ancyra, in Galatia, was present at a council of Ancyra in 314, as bishop of that city. He was also at the council of Nice in 325, where he signalized himself against the Arians; and it is concluded, from the testimony of Epiphanius, that he died in 372, when he had been bishop almost 60 years, and had lived almost or quite a century. Socrates says, that in opposing Asterius, against whom and other Arians he wrote

a book

a book in the year 334 or 335, Marcellus went into the other extreme, and embraced the opinion of Paul of Samosata, who says, that Jesus Christ is a mere man. He was deposed by an assembly of bishops at Constantinople, in 336, but restored by the synod at Sardica in 347. His book, which was a large work, and the only one he had published, was answered by Eusebius of Cæsarea, from whose quotations and arguments, as well as from Marcellus's letter and confession of faith, delivered to Julius, bishop of Rome, about the year 341, which is preserved by Epiphanius, that he received the same scriptures with other Christians, and paid them a like respect. Socrates and Sozomen seem to have supposed, that he adopted the opinion of Paul of Samosata; but Eusebius continually charges him with Sabellianism. Theodoret says, that he denied a trinity of persons. However, there have been formerly, as well as lately, different apprehensions concerning the real sentiments of Marcellus; but, according to Dr. Lardner, there is sufficient reason to think, that he was a Sabellian or Unitarian. Montfaucon is of opinion, that not long before his death, about the year 372, he sent a deputation to Athanasius, with a confession of his faith, completely orthodox; but this story, as Dr. Lardner thinks, is not well supported. If the doctrine of Marcellus be carefully examined, it will appear, says Mosheim, that he considered the Son and Holy Ghost as two emanations from the divine nature, which, after performing their respective offices, were to return again into the substance of the Father; and every one will perceive, at first sight, how incompatible this opinion is with the belief of three distinct persons in the Godhead. Lardner's Works, vol. iv. Mosheim's Eccl. Hist. vol. i.

MARCELLIN, ST., in *Geography*, a town of France, and principal place of a district, in the department of the Isère; 30 miles S.E. of Vienne. The place contains 3047, and the canton 14,589 inhabitants, on a territory of 240 kilometres, in 16 communes.—Also, a town of France, in the department of the Rhône and Loire; 9 miles S.S.E. of Montbrison.

MARCELLINO, a town of Naples, in Calabria Citra; five miles E. of Scalea.

MARCELLINUS, AMMIANUS, in *Biography*. See AMMIANUS MARCELLINUS.

MARCELLINUS, pope, a native of Rome, succeeded to the see of that city in the year 296. He was accused by the Donatists of having apostatized under the Dioclesian persecution; of having given up the scriptures to be burnt by the Pagans; and of offering incense even to the gods. It should, however, be observed, that the innocence of Marcellinus was defended, and his conduct justified by St. Augustine and Theodoret, who affirm that he acquired great glory during the persecution. He presided over the Roman church something more than eight years, and died in the year 304. Moreri.

MARCELLINUS, count of Illyria under the emperor Justinian, drew up a chronicle, commencing at the point in which Jerome finishes, and carrying it down to the year 534. It is much applauded by Cassiodorus, who says that the count also composed a very minute description of Constantinople and Jerusalem. The chronicle has been several times printed, first by Schoonhovius, in the sixteenth century; then by Joseph Scaliger, and still more correctly by father Sirmond. Moreri.

MARCELLO, BENEDETTO, a Venetian nobleman, descended from one of the most illustrious families of that republic; he had cultivated music so seriously and successfully as a dilettante in the art, under the guidance of the celebrated

Venetian maestro di capella, Gasparini, that no contemporary professor was more revered for musical science, or half so much praised for his abilities as a composer, as Marcello. This accomplished nobleman, besides his musical productions, consisting of psalms, operas, madrigals, songs, and cantatas, was frequently his own poet, and sometimes assumed the character of lyric bard for other musicians. It is probable that Marcello had received some disgust in his early attempts at dramatic music; for, in 1720, he published a furious satire upon composers, singing-masters, and singers in general, under the title of "Teatro alla Moda," or "An easy and certain Method of composing and performing Italian Operas in the modern Manner." But his great musical work, to which the late Mr. Avifon's encomiums and Mr. Garth's publication to English words, have given celebrity in our own country, was first printed at Venice in eight volumes folio, under the following title: "Estratto poetico-armonico, Parafrafi sopra i primi 50 Salmi, Poesia di Girolamo Ascanio Giustiniani, Musica di Benedetto Marcello, Patrizj Veneti, 1724 & 1725." There is a long and learned preface to the first volume, in order to give weight and authority to the author's plan and style of composition. But besides the great display of musical reading, sagacity, and superior views to any of his predecessors, letters are prefixed to each volume from the author's friends and admirers, in the same encomiastic strain as the recommendatory verses, with which almost every book was ushered into the world during the seventeenth century. But not dazzled by these, or the hyperbolic praises of Algarotti or Avifon, we have conscientiously examined the whole eight volumes of the Italian edition, and find, though there is considerable merit in the work, that the author has been *over-praised*: as the subjects of many of his fugues and airs are not only common and old-fashioned at present, but were far from new at the time these psalms were composed. But Marcello was a Venetian nobleman, as Venosa was a Neapolitan prince; both did honour to music by cultivating it; but both expected and received a greater return in fame, than the legal interest of the art would allow. Marcello was a disciple of Gasparini, and died in 1741.

We found still subsisting at Venice, a society for the performance of Marcello's compositions exclusively, and were invited to one of its meetings. Several of Marcello's psalms were here very well sung by the Abate Martini and some other dilettanti, among whom one had a very good bass voice, and between the psalms, sung Marcello's famous cantata, called Cassandra, where this composer has entirely sacrificed the music to the poetry, by changing the time or style of his movement at every new idea which occurs in the words; this may, perhaps, shew a composer to be a very sensible man, but at the same time it must discover him to be of a very phlegmatic turn, and wholly free from the enthusiasm of a creative musical genius. And, indeed, since melody has been allied to grace and fancy, musical disjointed thoughts on various subjects would be but ill received by the public. One of these gentlemen performers was old enough very well to remember Benedetto Marcello, and favoured us with several anecdotes concerning him and his family which still subsisted, and the head of it then was ambassador from the state to the Porte.

Marcello was not only his own poet in dramas which he set to music, but sometimes furnished words to other musical composers. He was author of a drama called "Arato in Sparta," which was set by Ruggieri, and performed at Venice in 1704; and in 1710 he produced both the words and the music of an oratorio, called "Giuditta." He set the

"Psyche" of Cassini, about the same time. In 1718, he published sonnets of his own writing, without music: and in 1725 he both wrote and set a serenata, which was performed at the imperial court of Vienna.

To some of his madrigals and cantatas, of which we prefer the composition to that of many of his psalms, we were told at Venice that he was his own poet.

But we have lately been favoured with a complete score of an oratorio by Marcello, of which we had never before heard of the existence. Its title, which is somewhat long, and its subject singular for an oratorio, is the following:

"Il Trionfo della Poesia, e della Musica, nil celebrarsi la Morte, la Esaltazione, e la Incoronazione, di Maria sempre Vergine assunto in cielo, Oratorio fagro a 6 voci 1733. Musica e Poesia di Benedetto Marcello."

The interlocutors are Poetry, Music, Painting, Sculpture, and chorus of Poets, Liberal Arts, and Old Musicians.

But these personifications are not so wide from sacred subjects as Alexander's Feast, and Semele, which are indeed sacred subjects of Paganism. And though the subject of this drama may be too playful, and the airs too gay for an oratorio, yet it is amusing to see how a great man may amuse himself in trying to amuse others. The airs are much superior to those of the noble author's psalms, and more ingeniously accompanied.

The overture, which begins with a spirited movement, ends with an admirable fugue in double counterpoint, instead of an air. There are ingenious airs and duets in echo, in the first part, and the coro finale is an alla-breve fugue on the hexachords.

In the second part there are many curious airs, duets, and chorusses, well accompanied; and all in clear and good counterpoint, and though it is called an oratorio, the movements are as gay and cheerful as any secular music of the same period. It must be owned that the chorusses and accompaniments of Handel's oratorios have made the English fastidious about sacred music. But Marcello must ever be admired for Italian grace and smoothness, and Handel for German force and vigour.

MARCELLO, *St.*, in *Geography*, a town of France, in the department of the Dora; 5 miles S.E. of Aosta.

MARCELLUS, surnamed *EMPIRICUS*, *the Empiric*, in *Biography*, was a native of Bourdeaux, and held an appointment under the emperors Theodosius and Arcadius. He died in the reign of Theodosius, the younger, who ascended the throne of the eastern empire in the year 408. It does not appear that Marcellus pursued the study of medicine as a profession, but took it up as an amateur, without acquiring any profound skill in it. He compiled from authors, both ancient and contemporary, and especially from Scribonius Largus, whom he copies literally without acknowledgment, and also from popular report, a collection of medicines and receipts for all the diseases of the body; in which, however, his superstition is more conspicuous than his judgment. Nevertheless his work has been preserved, and printed under the title of "De Medicamentis empiricis physicis et rationalibus Liber à Jano Cornario verus," Basil, 1536, &c. and was included among the "Medicæ Artis Principes," collected by Henry Stephen. Marcellus dedicated this compilation to his children, in an epistle which is preserved, with a view of teaching them the means of relieving their diseases by simple remedies; but at the same time he counsels them not to neglect the more compound ones when necessary, and to consult the most expert physicians before they employ them. Eloy Dict. Hist.

MARCELLUS DONATUS, a physician of the sixteenth cen-

ture, quitted the practice of his profession, and became secretary to the duke of Mantua. He is known as the author of a compilation of medical cases and observations, collected from the Greek, Arabian, and later writers, who had preceded him. This work was first published at Mantua, in 1586, quarto, and afterwards at Venice, 1588, and 1597, in six books, with the title of "De Historiâ Medicâ Mirabili Lib. VI." Horstius afterwards republished it at Franckfort, in octavo, in 1613, with a seventh book, on diseases reputed magical, and on extraordinary abstinence. Marcellus was also author of a tract, "De Variolis and Morbillis," printed at Mantua in 1569, quarto, and 1597, octavo, with another tract, "De Radicé purgante, quam vocant Mekoakan." Eloy, loc. cit.

MARCELLUS, MARCUS CLAUDIUS, a celebrated Roman general, descended from a plebeian, but an ancient and consular family, entered early into the military service of his country, and obtained many honorary rewards for his valour and heroism. He was elected consul with Cn. Cornelius Scipio in the year 222 B.C. They were, immediately after their election, obliged to take the field against the enemies of the republic; and Marcellus was singled out by Viridomarus, king of the Gætatæ, for single combat. The consul soon destroyed his enemy, and consecrated his spoils to Jupiter Feretrius, which being reckoned propitious to his designs, he attacked the enemy, and gained a complete victory. On account of this success, a triumph was decreed to Marcellus, of which the noblest ornaments were the *opime* spoils, that is, those taken from a slain king. The greatness of this distinction may be inferred from the lines which are referred to him in Virgil's prospective view of the Trojan progeny:

"Aspice ut insignis spoliis Marcellus opimis
Ingreditur, victorque viros supereminet omnes."
Æneid vi.

In the second Carthaginian war, Marcellus was appointed prætor of Sicily, and had got ready a fleet for that service, when the event of the fatal battle of Cannæ induced the senate to send him to take command of those who survived that disaster. He threw himself into Nola, which was threatened by Hannibal with a siege, and gave that commander a considerable check, which revived the courage of the Romans, and saved the place. In the year B.C. 215, Marcellus was again unanimously chosen consul, but a thunder-storm happening at the time of assembly, it was thought the election was displeasing to the gods, and he refused to accept the office, though pressed to it by the people. Fabius Maximus was elected in his stead, and Marcellus was continued in a proconsular command over the troops at Nola. After this he was chosen consul in connection with Fabius Maximus, and thus it was said, Rome was defended at the same time by her *sword* and her *shield*, which were the epithets applied to these two great commanders. Marcellus was now called to active exertions in Sicily, in which island the Carthaginian interest was very prevalent; he invested Syracuse, the capital, then one of the richest and strongest cities in this part of the world. He first proposed terms of accommodation, which being rejected, he laid siege to the city by land and by sea, taking command of the Roman fleet upon himself, while the prætor Appius commanded the land forces. This siege was rendered very remarkable by the various mechanical contrivances of the great Archimedes for its defence. By their means, the first attempts of the Romans were defeated with great loss: and Marcellus, converting the siege into a blockade, led the greater part of his troops against the revolted cities of Sicily, many of which he reduced to obedience.

dience. After his consulship was expired, he was continued as proconsul in the chief command in Sicily, and bent every effort to the finishing a siege upon which the eyes of all parties were attentively fixed. Marcellus determined on making an assault upon Syracuse, and fixed on the ensuing festival of Diana for this purpose, in which it was imagined the garrison would probably be buried in wine and sleep. At the appointed time a choice band of troops scaled the walls without discovery, and certain quarters of the city were taken without resistance. Marcellus, surveying from an eminence the vast and opulent city which was about to suffer all the miseries of a capture, is said to have shed tears, because he could not persuade the inhabitants to save themselves from plunder by a timely surrender. They were deaf to remonstrances, and Marcellus had to sustain a furious attack from the Carthaginians without, and the Syracusans within, which he repulsed with vast loss to the assailants. A plague which broke out in Syracuse added to the calamities of that unfortunate city: it ravaged likewise the Carthaginian camp to such a degree as to break it up after carrying off the commander. It was not, however, till the end of three years, that Syracuse was taken by assault, when it was impossible to save the inhabitants from the effects of a sack: the houses were pillaged, and many citizens were put to the sword, among whom was Archimedes, whose fate was particularly afflicting to Marcellus, and who was slain while he was calmly working a mathematical problem. The Roman commander, as soon as he was able, put an end to the atrocities of his soldiers, and displayed much personal clemency and humanity to the vanquished, but he carried away all the public monuments of art which decorated Syracuse for the ornament of Rome. Marcellus continued some time longer in Sicily, but his last action ended in a considerable victory obtained over the combined forces of Hanno and Epicydes, after which he returned to Rome with great glory. In the year 210 B.C. he was again chosen consul, when he was accused by the Syracusans with cruelty and a violation of treaty. He was, however, after due enquiries, acquitted of the charges, and his subsequent behaviour would have done honour to any man: he raised up the Syracusan deputies, who had been his accusers, and had fallen at his feet to implore forgiveness, assured them not only of his pardon, but of his future protection, and obtained of the senate that the people of Syracuse should be reinstated in their liberties, and considered as the allies of Rome. They, unwilling to be behind in respect for his manly virtues, expressed their gratitude to him by a decree, that when he or any one of his family should visit Sicily, the people should walk in procession before him, crowned with garlands, and celebrate the day with public sacrifices; and that thenceforth the whole island should be under the peculiar patronage of the Marcelli. After this Marcellus was a second time called upon to oppose Hannibal. He displayed as usual his great military talents in his operations against this general, but was not sufficiently vigilant against the snares of his adversary. He imprudently separated himself from his camp, and was killed in ambuscade in the 60th year of his age, and in his fifth consulship, being the year 208 B.C. When the body of this great commander was brought to Hannibal, he surveyed it a considerable time in thoughtful silence; and caused it to be buried, or, as others say, to be burned on a funeral pile, and then sent the ashes enclosed in a silver urn, and crowned with laurel, to his son. Plutarch.

MARCELLUS I., pope, a native of Rome, became a presbyter under Marcellinus, and was his successor in the bishopric of that city in the year 308, after the see had been vacant for more than three years and a half. The particulars

relating to this pope are not given on sufficient authority. It is said, in his epitaph, written by pope Damasus, that his firmness in maintaining the discipline of the church, and in obliging those who had fallen during the times of persecution to give proof of the genuineness of their repentance, excited against him the general hatred, which was not confined to private disputes and divisions, but ended in public tumults, bloodshed, and murders. He adds, that Marcellus was sent into banishment, and died in the second year of his pontificate, in the year 310. The church of Rome has given him a place in her list of martyrs, but in the most ancient martyrologies he has only the title of confessor. Moreri. Bower.

MARCELLUS II., pope, a native of Fano, in the Marche of Ancona, was son to the receiver-general of the revenues of the holy see. He was educated at Sienna, and honourably distinguished himself in literary pursuits. He afterwards went to Rome under the pontificate of pope Paul III., who appointed him his principal secretary. He accompanied cardinal Farnese, the nephew of the pope, to attempt to bring about a reconciliation between Francis I. and the emperor Charles V.: he at this time had the title of bishop, and was promoted to three different sees in succession, and upon his return to Rome, Paul created him cardinal presbyter of the holy cross of Jerusalem, and nominated him one of the presidents of the council of Trent. He succeeded to the popedom on the death of Julius III., in the year 1555. He is represented as being a man of inflexible integrity, of invincible resolution and constancy, and as having formed great designs for the reformation of the court and of the clergy, but he died before he could carry any of them into execution, and within a month of his consecration. Bower. Moreri.

MARCELLUS, in *Geography*, a military and post-town of America, in Onondago county, New York, situated on Skaneateles lake, 11 miles W. of Onondago castle; incorporated in 1794, and containing 909 inhabitants.

MARCENAT, a town of France, in the department of the Cantal, and chief place of a canton, in the district of Murat. The place contains 2058, and the canton 8957 inhabitants, on a territory of 282½ kilometres, in 7 communes.

MARCENOPOLI, a town of Bulgaria, anciently Marcianopolis: it was destroyed by Attila; 20 miles W.N.W. of Varna. N. lat. 43° 10'. E. long. 27° 24'.

MARCGRAVE, or MARGRAVE, a kind of dignity in Germany, answering to our marquis.

The word is derived from the German *marche*, or *marke*, which signifies a *frontier*, formed, as Junius conjectures, from the last syllable of the Greek *τεκμαρ*, which signifies both a *mark*, and a *limit*; and *graffe*, *count*, *governor*; marcgraves being originally governors of cities lying on the frontiers of a country or state.

MARCGRAVIA, in *Botany*, was named by Plumier, in memory of George Marcgraf de Liebstad, a native of Saxony, who travelled with Piso in the Brasils, and subsequently visited the coasts of the Mediterranean. He died in passing over to Africa, at the age of 34, in 1644. His account of the plants, animals, and inhabitants of the Brasils, has been published by De Laet, along with some of the writings of Piso, in a folio volume, dated 1648, illustrated with wooden cuts. The eighth book of this is repeated in another edition of the works of Piso, with those of Bontius, published at Amsterdam, in 1658. Marcgraf is mentioned by Piso, p. 107 of the last-mentioned volume, as "his excellent and very diligent domestic, of some of whose drawings and observations he has made use, which he acknowledges,

acknowledges, lest evil-minded persons should accuse him of enriching his works with stolen decorations." Linnæus says, *Crit. Bot.* 79, that a relation of Marcgraf has accused Piso of deriving all his information from the papers of the former, after his death. He is reported, moreover, to have been himself the servant of the man he attempts, in that respect, to defame. It seems that Marcgraf was of a good family, unless his surname (de Liebstad) merely, as Haller supposes, indicates the place of his birth. Piso became a physician at Amsterdam. (See PISONIA hereafter in its proper place.) Linn. Gen. 260. Schreb. 347. Willd. Sp. Pl. v. 2. 1127. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 284. Juss. 244. Plum. Gen. 7. t. 29. Lamarck Illustr. t. 447.—Class and order, *Polyandria Monogynia*. Nat. Ord. *Putamineæ*, Linn. *Capparides*, Juss.

Gen. Ch. *Cal.* Perianth inferior, permanent, of six imbricated, roundish, broad, concave leaves; the two outermost largest. *Cor.* of one petal, vertical, ovate, somewhat conical, undivided, covering the organs of impregnation like a cap, at length separating all round at the base, deciduous. *Stam.* Filaments numerous, awl-shaped, short, spreading, deciduous; anthers large, ovate-oblong, erect, *Pist.* Germen superior, ovate; style none; stigma capitate, permanent. *Peric.* Berry globose, coriaceous, of many cells, and many imperfect valves. *Seeds* numerous, small, oblong, lodged in soft pulp.

Ess. Ch. Corolla of one petal, vertical, cap-shaped, deciduous. Calyx of six imbricated leaves. Berry of many cells. Seeds numerous.

1. *M. umbellata*. Climbing Marcgravia. Linn. Sp. Pl. 719. Jacq. Amer. 156. t. 96. (*M. scandens*; Browne Jam. 244. t. 26. Plum. Ic. t. 173. f. 1.)—Native of woods in South America and the West Indies. Browne says it is frequent in Jamaica. The *stem* is at first slender and weak, climbing up the trunks of large trees, by means of fibres like those of ivy, and furnished with alternate heart-shaped, emarginate, entire *leaves*, on very short footstalks. When it reaches the summit, it "lays its trunk," says Browne, "more commodiously over some of the larger branches of the tree: then it begins to strengthen, and casts many slender, dependent and subdivided branches from the upper parts. But as it increases at the top, the stem grows thicker, separates from the supporter, throws off its now useless leaves and roots (fibres), and appears a strong woody shrub, whose trunk is frequently no less than four or five inches in diameter." The pendulous *branches* are a foot or two in length, roundish, warty, bearing numerous, alternate, elliptic-oblong, pointed, entire, smooth, somewhat fleshy *leaves*, on short stalks, spreading in two directions, each about three inches long, furnished with a strong rib, and several small transverse veins. *Stipules* none, except a little intrafoliaceous gland, just above the insertion of each footstalk. *Umbel* terminal, pendulous, solitary, simple, of about a dozen *flowers*, on widely spreading downy stalks, swelling upwards, above an inch long. The *flowers* appear to be turned downwards. Their *corolla*, while it remains, gives them the appearance of small acorns, being about one-third of an inch long, and might easily be mistaken for a seed-vessel. Of its colour we find no mention. The *fruit* is the size of a moderate gooseberry, with a thick rind, which is but imperfectly disposed to split into valves. The internal partitions originate from it, and are narrow and thin. The pulp and *seeds* are said to be of a vivid scarlet. We presume, from the natural affinities of this plant, that it is of a poisonous quality. Its greatest peculiarity consists in four, five, or more appendages to the umbel, placed in

the centre, each on a stalk half the length of the flower-stalks. These are above an inch long, tubular, obtuse, and closed at the extremity, but furnished with a dilated lip at their orifice where the stalk is inserted. Being, from the position of the umbel, pendulous, Browne says they catch the water that trickles down the branch in rainy weather; but their use has not been fully explained. Linnæus supposed them *nectaries*. If such, they may serve to tempt insects or humming-birds to frequent the flowers, and assist impregnation, as in numberless other cases.

Willdenow has adopted another species, *M. coriacea*, from Vahl's *Eclogæ*. Of this magnificent plant we have been favoured by Mr. T. F. Forster with a fine specimen from Guiana. It has the habit of *M. umbellata*, but more elliptical, obtuse, coriaceous, shining, and almost veinless, *leaves*. The *umbel*, like all the other parts, is much larger. The supposed *nectaries*, or pouches, grow, without any stalks, on the lower part of each flower-stalk, and are shorter and more inflated than those of the former. This plant has certainly all the habit of the genus in question, but neither Vahl nor Willdenow seems to have known any thing of the *corolla*, which is totally different, consisting of five separate concave *petals*, so that it proves to belong to Schreber's genus *Afcium*, the *Norantea* of Aublet; which differs in that respect only from Marcgravia, having exactly the same sort of pouches, though they have been called *bractæas*, because the inflorescence in Aublet's plant is racemose. *Marcgravia*, therefore, differs from *Afcium* exactly as Swartz's *Calyptanthus* differs from *Myrtus*, and no further; for the difference in their inflorescence, which might have been thought of some moment, is done away by this new species, which is in that respect a *Marcgravia*, though in generic character an *Afcium*. See ASCIUM and CALYPTANTHUS.

MARCH, MARTIUS, in *Chronology*, the third month of the year, according to the common way of computing.

Among the Romans, March was the first month; and, in some ecclesiastical computations, that order is still preserved; as particularly in reckoning the number of years from the incarnation of our Saviour, which is done from the 25th of March.

In England, (before the alteration of the style,) March, properly speaking, was the first month in order, the new year commencing from the 25th; though, in compliance to the customs of our neighbours, we usually ranked it as the third; but, in this respect, we spoke one way, and wrote another.

Till the year 1564, the French reckoned the beginning of their year from Easter; so that there were two months of March in one year, one of which they called *March before Easter*, and the other *March after Easter*; and, when Easter fell within the month of March, the beginning of the month was in one year, and the end in another.

It was Romulus who divided the year into months; to the first of which he gave the name of his supposed father Mars. Ovid, however, observes, that the people of Italy had the month of March before Romulus's time; but that they placed it very differently, some making it the third, some the fourth, some the fifth, and others the tenth month of the year.

In this month it was that the Romans sacrificed to Anna Perenna; that they began their comitia; that they adjudged their public farms and leases; that the mistresses served the slaves and servants at table, as the maîtres did in the Saturnalia; and that the Vestals renewed the sacred fire.

The month of March was always under the protection of Minerva, and always consisted of thirty-one days. The ancients

cients held it an unhappy month for marriage, as well as the month of May.

MARCH, in *Geography*, a market-town in the parish of Doddington, hundred of Witchford, isle of Ely, Cambridgeshire, England, is situated 26 miles distant from Cambridge, 15 from Ely, and 81 from London, nearly midway between Chatteris and Wisbech, on the banks of the river Nene; from which circumstance it has the advantages of a considerable trade. The population, as returned to parliament in the year 1801, was 2514, occupying 555 houses. The chapel is a spacious edifice, with a spire, erected about the year 1343. A market is held on Fridays, and three fairs annually. Many Roman remains have been discovered in this vicinity. When the road was making from March to Wisbech, in the year 1730, three urns were dug up, full of burnt bones and ashes; and also a pot, containing 160 Roman denarii, of all the emperors from Vespasian to Antoninus Pius, but chiefly of the latter. Various other coins have been found, and an altar 21 inches high. *Beauties of England and Wales*, vol. ii.

MARCH, in *Military Language*, is in general the motion of a body of men from one place to another.

The beat of the drum, upon particular occasions, is likewise called the *march*; which see. It is likewise a word of command, when a battalion is to alter its disposition.

Neither music nor drums are now used to regulate the march, which is in three measures. 1. Ordinary time, in which 75 paces are taken in a minute. 2. Quick time, in which there are 108 steps in a minute. 3. The quickest time, or wheeling march, which is at the rate of 120 steps of 30 inches each, or 300 feet in the minute. This last is used only for wheeling. For a more particular account of the subject of this article, see BATTALION.

As many accidents may happen in the march of an army from defiles, marshes, woods, and the like, it is the prudence of a general to order his march accordingly, and to take care that the columns of his army have a free communication one with the other. The march of an army is composed of an advance guard, the main body, and the rear guard, and is sometimes in two, four, six, or eight columns, according as the ground will allow.

The order of march of the troops must be so disposed, that each should arrive at their rendezvous, if possible, on the same day. The quarter-master-general, or his deputy, with an able engineer, should sufficiently reconnoitre the country, so as to obtain a perfect knowledge both of that and of the enemy, before he forms his routes. Before a march, the army generally receives several days' bread. The quarter-masters, camp-colour men, and pioneers, parade according to orders, and march immediately after, commanded by the quarter-master-general, or his deputy. They are to clear the roads, level the ways, make preparation for the march of the army, &c. The "general," for instance, beats at two, the "assembly" at three, and the army commence their march in 30 minutes after. Upon beating the "general," the village and general officer's guards, quarter and rear-guards, join their respective corps, and the army pack up their baggage. Upon the "assembly," the tents are to be struck, and sent, with the baggage, to the place appointed. The companies draw up in their several streets, and the rolls are called. At the time appointed, the drummers are to beat a march, and fifers play at the head of the line; upon which the companies march out from their several streets, form battalions as they advance to the head of the line, and then halt. The several battalions will be formed into columns by the adjutant-general, and the order of march, &c. be given to the general

officers who lead the columns. The cavalry generally march by regiments or squadrons. The heavy artillery always keep the great roads, in the centre of the columns, escorted by a strong party of infantry and cavalry. The field-pieces move with the columns. Each soldier generally marches with 60 rounds of powder and ball, and three good flints; one of which is to be fixed in the cock of his fire-lock. The routes must be so formed, that no column may cross one another on the march. See BATTALION.

MARCH, in *Music*, a military air played by martial instruments to regulate and mark the steps of the soldiery, to which the drums usually beat time. There are military pieces for field instruments on the parade, which are called *marches*, though the regiment or corps is stationary.

In Persia, according to Chardin, when a building is to be pulled down, the ground to be levelled, or any work to be performed that requires dispatch, and the united efforts of a multitude, all the inhabitants of a district are assembled, who work to the sound of instruments, and the business is done with more zeal and promptitude than it would be in silence.

Marshal Saxe, in his *Reveries*, shews, that the effect of drums is not confined to a mere useless noise; but as the pulsations are more or less rapid, they naturally inform the soldier to accelerate or retard his pace. It may also be said, that the melody or movement of marches should have different characters, according to the occasions upon which they are played; and this is implied by the names given to certain beatings of the drum, as the general, the retreat, the charge, &c.; but all the advantages of such signals have not been taken that might be. The measures that are beaten or played, have hitherto been confined to one style, to suit the common beat of the drum. And there are many airs that are denominated marches which fulfil that object very imperfectly. The French troops (said Rousseau, in 1768,) having few military instruments for the infantry, except fifes and drums, have likewise very few marches, and these, in general, ill composed; but how admirable are those in the German troops. It is only the infantry and light horse that have particular marches. The kettle-drums of the cavalry have no regular march; the trumpets have only a single note sometimes, and never more than a *tantare*, or flourish. The march, pace, or movement, in music, is used figurately by the French in speaking of the succession of sounds in melody, which follow each other in a certain order; as the base and treble proceed by contrary motion, the base moves in quavers, the treble in semiquavers, &c. For the agreement between the musical air and the military steps, Rousseau has given the first part of the march of the Mousquetaires of the king of France at the time when his *Dict. de Mus.* was printed, which we have copied in our musical plates. It was found by English travellers, four or five years after Rousseau's *Dict.* was published, that the French military music in Flanders was very much improved by the adoption of the instruments and style of music used in the bands of the Walloon and German regiments in the Austrian Netherlands. *German Musical Tour*, vol. i.

In the Supplement to the first edition of the *Encyclopédie*, it is truly said, that a march should be always composed in common time, with an odd crotchet or quaver at the beginning; and that it is almost impossible to march in cadence to a movement in triple time, unless it is composed in such a manner that the caesura is felt at the end of every two bars; that is to say, unless the composer has written an air in common time, as if it were in triple.

The arsis, or up part of the bar, naturally marks the lifting up of the foot in marching; on which account the air usually begins with an odd note.

Of the marches and military music of our ancestors, we may form some judgment by the remains of our venerable composer, William Bird, transcribed in the Virginal book of lady Nevil, which is still preserved, and in the possession of Dr. Burney. This book, curiously written in 1591, contains no less than forty-two pieces by the admirable Bird; among which are the following military movements, set for the Virginal by that venerable composer, and very neatly copied on six-line paper.

The orthography of the names of the tunes, and of the copyists termination of the MS. are here preserved.

The March before the Battell.

The Battell.

The March of Footmen.

The March of Horsemen.

The Trumpetts.

The Irishe March.

The March to Fighte.

Tantara.

The Battells bejoined.

The Retreat.

The Galliarde for the Victorie.

We shall give the motivo, or subject, of some of these pieces, on one of the music plates.

The copyist of this curious MS. having terminated his labour, has made the following record of his achievement.

finis :

Finished and ended the seventh of September in the yeare of our Lorde God, 1591, and in the 33d yeare of the raigne of our latesaigne ladie Elizabeth by the grace of God queene of Englande, &c.

By me Jo: Baldwine of Windfore :

Laudes : deo.

MARCH, AUSIAS, in *Biography*, the best known of the Limosin poets, was born in Valencia, of Catalan parents, and flourished about the middle of the 15th century. He was educated in the duke of Gandias household, and married a woman of noble family, but, like Petrarch, whose example he followed, he fell in love with another man's wife, and spent his time in writing verses upon her in the Provençal style. Could the Catalans have shaken off the yoke of Arragon, against which they struggled, their dialect would have become a cultivated tongue, and Ausias March would have been the father of its poetry. As it is, his reputation is very great, considering the obsolete language in which he wrote. His poems have been frequently printed: the earliest edition is that of Valencia, in 1539. The Valladolid edition of 1555 contains a copious glossary, with observations on the grammar and pronunciation of the language. *Gen. Biog.*

MARCHAND, PROSPER, born towards the close of the 17th century, was brought up in the bookselling trade at Paris, and acquired a great knowledge of books and literary anecdotes. His attachment to the Protestant religion, and his connection with Bernard, the continuator of the "Nouvelles de la Republique des Lettres," induced him to remove to Holland, where he acted some time as a bookseller, till at length he entirely devoted himself to literature. His studies led him chiefly to bibliography and French history, and on these topics he was occasionally consulted by persons from all parts of Europe. He took an active and leading part in the "Journal Litteraire," and he furnished other literary journals with curious extracts, which he had collected by his extensive course of reading. He died at an advanced age in 1756, and left his library and manuscripts to the university of Leyden. He had published, in 1740,

"L'Histoire de l'Imprimerie;" "Dictionnaire Historique; ou, Memoires Critiques et Litteraires;" and a new edition of "Bayle's Dictionary and Letters."

MARCHAND, JOHN LEWIS, a celebrated French organist during the early part of the last century, usually performed at the Jesuits' church of St. Benoit, rue St. Jaques, and at the Cordeliers, where he was followed by all Paris, and always heard with new pleasure. Rameau, his friend and most formidable rival, frequently declared, that the greatest pleasure of his life was hearing Marchand perform; that no one could be compared to him in the management of a fugue; and that he believed no musician ever equalled him in extempore playing. The Germans relate a story, which no French writer has confirmed: that Marchand, being at Dresden, challenged to a trial of skill all the organists of Germany, which none but Sebastian Bach ventured to accept. It was an honour, says M. Marpurg, for Pompey to be only defeated by Cæsar, and to Marchand to have no superior but Bach. His independent and disinterested spirit, says M. Laborde, prevented him from ever thinking of his fame or his fortune. As he chiefly loved to play extempore, he seldom committed his thoughts to paper, and has left only two books of harpsichord lessons behind him. He was more happy in his mind and fancy when he played the organ to two or three real connoisseurs, during the hours that the church was shut, than when on festival days he drew together a crowded congregation to hear him. It was at such times that he chiefly exerted himself and seemed inspired; on other days he only performed what belonged to the service of the mass. This musician was born at Lyons in 1669, and died at Paris in 1732.

MARCHANTIA, in *Botany*, so named by John Marchant, in the Memoires de l'Acad. des Sciences for 1713, in honour of his father Nicholas, author of several essays in the same collection. There seems to be a confusion betwixt these two persons, and Nicholas the son of the former, in Haller's *Bibl. Bot.* and Dryander's *Bibl. Banks.* *Linn. Gen.* 565. *Schreb.* 763. *Mart. Mill. Dict.* v. 3. *Hedw. Theor.* 96. t. 24—26. *Spreng. Crypt.* 342. *Huds.* 519. *With.* v. 1. 388. t. 15. f. 60—67. v. 3. 884. *Juss.* 9. *Lamarck Dict.* v. 3. 107. *Illustr.* t. 876. *Mich. Gen.* 1. t. 1. (*Hepatica*; *Mich. Gen.* 3. t. 2. *Lunularia*; *ibid.* 4. t. 4. *Lichen*; *Dill. Musc.* 515. t. 75—77.)—Class and order, *Cryptogamia Alga*, *Linn. C. Hepatica*, *Schreb. Nat. Ord. Alga*, *Linn. Hepatica*, *Juss.*

Gen. Ch. Male, either stalked or sessile. *Cal.* Perianth a membranous border, undivided or lobed, permanent, surrounding a tuberculated horizontal disk. *Cor.* none. *Stam.* Filaments none; anthers numerous, oval, of one cell, immersed vertically in the disk, each encompassed by a vertical ring, and opening by a pore at the surface of the disk.

Female, on the same, or a separate, plant. *Common Cal.* large, stellated, hemispherical or conical, flowering underneath, the florets pointing downwards. *Perianth* sessile, bell-shaped, membranous, tender, coloured, with four or five teeth. *Cor.* Veil sessile, shorter than the perianth, oblong or somewhat globose, membranous, very thin, crowned with the style, and at length splitting at the top into from two to five segments, one of which retains the style at its summit. *Pist.* Germen sessile, oblong, somewhat globose, invested with the veil; style straight or incurved, short, prominent from the top of the veil; stigma simple. *Peric.* Capsule attached by a capillary short stalk, obovate, of one cell, opening at the top with from five to ten, usually eight, teeth, which at length become revolute. *Seeds* very numerous, globose, attached to several elastic, spirally contorted, threads.

MARCHANTIA.

Obf. Some species bear, besides the flowers, little cups, toothed at their edges, full of grains which prove to be buds, *gemmae*. Linnæus, trusting to Dillenius, mistook these for the female fructification, and the real female flowers for male ones, the seeds being supposed the pollen. The true male flowers, ascertained by Hedwig, were, in the species in which they were observed, thought a mere variation of form.

Eff. Ch. Male, Calyx valver-shaped. Anthers numerous, annulated, imbedded in its disk.

Female, Calyx peltate, flowering underneath. Capsules deflexed, opening at the top by several revolute valves. Seeds attached to elastic filaments.

This genus is next akin to *Jungermannia*, (see that article,) with which it very much agrees in habit, especially with those species that have no stem separate from the leaves, and grows like them in damp umbrageous places. The herbage however is, on the whole, of larger dimensions than in *Jungermannia*, and the fructification more elaborate, or at least better defined, as well as essentially distinct in characters.

Five species are described as natives of Britain, and Linnæus has two besides, and we add an eighth from Scopoli, *his triandra*.

1. *M. polymorpha*. Star-headed Marchantia. Linn. Sp. Pl. 1603. Bulliard, t. 291. Hudf. n. 1. Engl. Bot. t. 210. (*M. squamis marginalibus, calyce plano*; Schmid. Ic. 38. t. 9. Marchantiæ 1—5; Mich. Gen. 2. t. 1. Lichen fontanus major, stellatus æquè, ac umbellatus, et cyathophorus; Dill. Musc. 523. t. 76. f. 6. L. domesticus minor, stellatus æquè, &c.; ibid. 527. t. 77. f. 7.)—Calyx of the female flowers cloven into about ten narrow segments.—Very common in damp places, about springs, wells, and shady court-yards, throughout Europe, varying much in size, in proportion to the moisture of its situation; being often a most troublesome weed in gardens, over-running pots that are obliged to be kept moist, as well as beds of alpine or American plants. It flowers about Midsummer, and is perennial. Few plants are endowed with such ample and pertinacious powers of propagation. The *fronds* spread horizontally, creeping close to the earth, stone, or wall, by means of dense, fibrous, soft, and silky radicles of a shining brown. They are several inches in extent, bluntly lobed, of a dark shining green, fringed with scales, and more or less reticulated; less reticulated and shining in Dillenius's t. 77. f. 7, though Schmidel observes that it is hardly possible to draw a line between these two varieties, or supposed species. The latter seems to grow in drier situations than the former. The upper surface of the *leaf* or *frond* is studded with several pale cups, toothed at their edges, half filled with green lenticular buds, as mentioned above. By these the plant is copiously increased, in less moist places, where it does not readily flower. The proper *flowers* grow from marginal clefts, on erect simple stalks, from one to three inches high, those of the females tallest, and on a separate plant. The common *calyx* of the latter is deeply cut into eight or ten deep, linear, radiant, obtuse segments, from the under side of which, towards their base, the flowers are produced. The seeds are yellow, and the spiral filaments to which they are attached, have an apparently spontaneous motion, which however arises merely from their elasticity, and exquisite susceptibility of moisture.

2. *M. chenopoda*. Goose-foot Marchantia. Linn. Sp. Pl. 1603. (*Lichen anapodocarpus*; Plum. Fil. 143. t. 142. Dill. Musc. 531. t. 77. f. 8.)—Calyx of the female flowers halved, palmate, with four obtuse segments.—Native of the West Indies, on moist rocks. The segments of the *frond* are oblong, sinuated or wavy at the edge. *Fruit-stalks* nearly

terminal. *Common calyx* of the female flowers remarkable for being cut away on one side, all its four segments being directed the other way, like the fingers of a hand, or toes of a web-footed bird. We have from Jamaica, gathered by Browne, what seems to answer to Plumier's figure and description, which Dillenius has copied; we have also the same from Dr. Swartz. In both specimens the upper side of the *frond* is besprinkled with fine pellucid dots or grains. Mr. Dickson esteems these specimens a different species from the original one of Plumier.

3. *M. cruciata*. Cross-headed Marchantia. Linn. Sp. Pl. 1604. Hudf. n. 2. (*Lichen feminifer lunulatus, florifer pileatus, tandem cruciatus*; Dill. Musc. 521. t. 75. f. 5. *Lunaria vulgaris*; Mich. Gen. 4. t. 4.)—Calyx of the female flowers in four deep, cross-like, tubular segments. Native of shady damp places in Italy, France, and England, fructifying in July. The *fronds* are smaller than in *M. polymorpha*, and dilated outwards. *Flower-stalks* each from a toothed cup on the disk of the leaf. *Common calyx* of the female flowers at first conical, but soon becoming deeply divided into four spreading, cruciform, tubular segments, from whose extremities the *capsules* and *seeds* are protruded. Dillenius has a remark unworthy of so great a philosopher, that "the flowers are rarely produced, but the seeds very frequently." Surely, as no seeds can come without flowers, this might have led him to discover that what he took for seeds were really buds!

4. *M. tenella*. Slender Marchantia. Linn. Sp. Pl. 1604. (*Lichen pileatus parvus carinatus, capitulis fimbriatis*; Dill. Musc. 521. t. 75. f. 4.)—Calyx of the female flowers hemispherical with a little point; its margin radiated.—Gathered by Gronovius in Virginia. The *frond* of this delicate species spreads circularly, but is not all together much above an inch broad. The *stalks* are nearly terminal, very slender, above an inch high. *Calyx* very convex, crowned with a minute blunt point, and fringed with numerous segments that bear the *capsules*.

5. *M. hemisphærica*. Hemispherical Marchantia. Linn. Sp. Pl. 1604. Hudf. n. 3. Engl. Bot. t. 503. Schmid. Ic. t. 34. (*Lichen pileatus parvus, foliis crenatis*; Dill. Musc. 519. t. 75. f. 2. *Hepatica media, capitulo hemisphærica*; Mich. Gen. 3. t. 2. f. 2.)—Calyx of the female flowers hemispherical, cloven into about five oval segments. Stalks naked at the base.—Native of Europe, about the banks of rivers and ditches, or the moist crevices of rocks, sometimes in exposed situations, flowering in the early spring. The *fronds* are lobed, forming broad patches; their upper surface granulated, of a fine green, often purplish at the edges. *Stalks* not above an inch high. *Calyx* convex, rounded, without any terminal point; the margin in five, or more, oval segments. *Capsules* and *seeds* black. By a strange oversight, a barren specimen of this species was described as a new genus by Forster, under the name of *Aitonia*, see his *Genera*, t. 74; and adopted by the younger Linnæus, by that of *Rupinia*; see his *Suppl.* 69 and 452.

6. *M. triandra*. Three-celled Marchantia. Scop. Carn. ed. 2. 354. t. 63. Web. Goett. 163. (*M. tenella*; Thunb. Prod. 175.)—Calyx of the female flowers hemispherical, undivided, of three or four cells.—Found by Scopoli in Carniola, by Weber in Hercynia, and by Thunberg at the Cape of Good Hope; for the original specimens of the *tenella* of the last-mentioned author prove to be this plant. We have others from Siberia, which appear the same, but their condition is not sufficiently good for us absolutely to decide. This is a small species, whose *fronds* are at most but an inch long. *Stalks* half an inch high, or thereabouts, purplish. *Calyx* convex, granulated, without a point; its

margin wavy, not cut or lobed. *Cells* three or four, very prominent underneath, furnished with long, taper, bristle-like appendages. The specific name alludes to the old Linnæan idea, of the female being the male flowers.

7. *M. androgyna*. Monoecious Marchantia. Linn. Sp. Pl. 1605. Dickf. H. Sicc. fasc. 4. 21. Crypt. fasc. 2. 17. With. 886. (Lichen pileatus angustifolius dichotomus; Dill. Musc. 520. t. 75. f. 3. Hepatica minor angustifolia, capitulo hemisphærico; Mich. Gen. 3. t. 2. f. 3.)—Calyx of the female flowers hemispherical, half four-cleft, of four cells.—Native of Italy, France, Switzerland, and Scotland. This is much larger than the last. *Fronde* two inches or more in length, various in breadth, smooth. *Stalks* one and a half or two inches high. *Calyx* very convex, smooth, its margin in four blunt lobes, beneath which the four *cells* are very prominent. Linnæus mistook his Siberian specimen above mentioned, which we judge to be *triandra*, for the true *androgyna*, and therefore erred in his specific character of this latter. We conceive Scopoli's *M. quadrata*, Carn. ed. 2. 355. t. 63, to be no other than the real *androgyna*.

8. *M. conica*. Conical Marchantia. Linn. Sp. Pl. 1604. Hudf. n. 4. Engl. Bot. t. 504. Schmid. t. 31. (Lichen vulgaris major, pileatus et verrucosus; Dill. Musc. 516. t. 75. f. 1. Hepatica vulgaris major, vel officinarum Italix; Mich. Gen. 3. t. 2. f. 1.)—Calyx of the female flowers ovate, pointed, with five marginal notches. Male flowers in sessile warts.—Common in damp shady places in Britain and other parts of Europe, but the female fructification is rare. The *fronds* are broad, reticulated, bluntly lobed, highly aromatic and fragrant, giving their perfume to the air, especially after rain, like many *Jungermannia*. *Stalks* from clefts between the lobes, two inches high, white and tender. *Calyx* conical, with four small marginal lobes. *Capsules* and seeds black. On separate plants from these are found hemispherical sessile warts, such as *M. androgyna* appears to bear on the same plant with the capsules, and which Hedwig believes to be the male flowers. We presume, however, that what are represented on a portion of a frond in *Engl. Bot.* are not these, but gemmiparous cups, like those of *M. polymorpha*, by which the plant is usually propagated. S.

MARCHAUX, in *Geography*, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Befançon. The place contains 382, and the canton 8894 inhabitants, on a territory of 220 kilometres, in 38 communes.

MARCHE, OLIVER DE LA, in *Biography*, son of a gentleman of Burgundy, entered, in early life, into the service of Philip the Good, duke of Burgundy, by whom he was highly valued. After this Charles the Bold raised him to the posts of master of the household and captain of his guards, and knighted him at the battle of Montlheri, in 1465. He was with that prince at the fatal battle of Nancy, and was made prisoner. We find him next, first master of the household to Maximilian of Austria, and afterwards to his son the archduke Philip, by whom he was sent on an embassy to the court of France after the death of Lewis XI. He died at Brussels in 1501, leaving behind him "Memoirs or Chronicles," relating to the two dukes of Burgundy; these were published at Lyons in 1562, and again at Brussels in 1616. He also wrote "Le Parement et le Triomphe des Dames d'Honneur;" "Traité sur les Duels et Gages de Bataille," and other pieces. Moreri.

MARCHE, La, in *Geography*, was before the Revolution a province of France, bounded on the N. by Berri, on the E. by Auvergne, on the S. by Limosin, and on the W. by Poitou; lying between 45° 45' and 46° 35' N. lat., and between 0° 45' and 2° 31' E. long.; being from N. to S. 10 leagues,

and 20 from W. to E. Its rivers are the Torion, the Great Creuse, the Gartempe, and the Vienne. This province was formerly under the dominion of the Romans, Visigoths, and Franks. Under the last of these powers it was governed by counts, and was confiscated by Philip the Handsome. Francis I. annexed it to the crown A. D. 1531. Some tracts of this province are tolerably fertile, yielding grain and fruits, and others are covered with excellent pasturage. The soil is composed of sandy and friable loams, some on granite, and others on a calcareous bottom. The chief towns in Upper Marche, on the eastern division, are Gueret, Ahun, Aigurande, Aubusson, Felletin, Bourgneuf, Grandemont, and Benevent; and those in Lower Marche are Bellac and Dorat. This province now principally constitutes the department of the Creuse, and part of that of Vienne.

MARCHE, a town of France, and principal place of a district, in the department of the Sambre and Meuse, situated on the Marfette, in the road from Paris to Liege. The place contains 1257, and the canton 6382 inhabitants, on a territory of 250 kilometres, in 25 communes. The parish-church is a handsome structure; 20 miles S.E. of Namur.

MARCHE, La, a town of France, in the department of the Vosges, and chief place of a canton, in the district of Neufchâteau, situated near the source of the Mouzon; 27 miles W.N.W. of Luxeuil. The place contains 1554, and the canton 13,928 inhabitants, on a territory of 335 kilometres, in 26 communes. N. lat. 48° 4'. E. long. 5° 22'.

MARCHE, La, a small territory of Switzerland, in the canton of Schwytz, situated S. of the lake of Zurich.

MARCHECK, or MAREK, a town of Austria, on the March; 14 miles N.W. of Presburg. N. lat. 48° 15'. E. long. 16° 56'.

MARCHENA, a town of Spain, in the province of Seville, situated on a hill, having in its suburbs the only well in the town or neighbourhood; seven miles S. of Carmona. It was anciently called "Colonia Marcia."

MARCHENOIR, a town of France, in the department of the Loir and Cher, and chief place of a canton, in the district of Blois; 15 miles N. of Blois. The place contains 421, and the canton 8340 inhabitants, on a territory of 260 kilometres, in 18 communes.

MARCHERS, or Lords MARCHERS, in our *Old Writers*, noblemen that lived on the marches of Wales, or Scotland. These, in times past, according to Camden, had their laws, and power of life and death, &c. like petty kings. But such powers were abolished by the stat. 27 Hen. VIII. cap. 27, and 1 Edw. VI. cap. 10.

MARCHES, MARCHIA, from the German, *march*, i. e. *limes*, or from the French *marque*, viz. *signum*, being the notorious distinction between two territories, are the limits between England and Wales, or Scotland; which last are divided into west and middle marches. (4 Hen. V. cap. 7. 22 Edw. IV. cap. 8. 24 Hen. VIII. cap. 9.) And there was formerly a court, called the court of the marches of Wales, where pleas of debt or damages, not above the value of 50*l.* were tried and determined; and if the council of the marches held plea for debts above that sum, &c. a prohibition might be awarded.

MARCHES, Les, in *Geography*, a town of France, in the department of Mont Blanc; four miles W. of Montmelian.

MARCHESI, LUIGI, in *Biography*, one of the greatest vocal performers which Italy has produced on the opera stage since the first establishment of the musical drama, arrived

rived in England in April, 1788. This finger, whose talents have been the subject of praise and admiration in every great theatre of Europe, where musical dramas are performed in the Italian language, first appeared at Rome in 1774, in a female character, the usual introduction of a young and promising singer, with a soprano voice and beautiful person. In 1775, he performed the second man's part at Milan with Pacchierotti, and at Venice with Millico; but the same year he was advanced to the principal character at Treviso. In 1776 and 1777, he sung as first man at Munich and Padua; and in 1778, he had worked his way to the great theatre of San Carlo at Naples, which is the criterion and post of honour of an opera singer. He continued here two seasons, and has since performed with increasing celebrity at Pisa, Genoa, Florence, Milan, Rome, Petersburg, Vienna, and Turin.

The "Giulio Sabino" of Sarti, was the first opera in which Marchesi performed on our stage. The elegant and beautiful music of this drama did not please so much here as it ought, and had done in other parts of Europe. Several of the songs, indeed, had been previously sung here at concerts, and did not appear new. Marchesi's style of singing is not only elegant and refined to an uncommon degree, but often grand and full of dignity, particularly in his recitatives and occasional low notes. His variety of embellishments and facility of running extempore divisions are truly marvellous. Many of his graces are new, elegant, and of his own invention; and he must have studied with intense application to enable himself to execute the divisions, and running shakes from the bottom of his compass to the top, even in a rapid series of half notes. But besides his vocal powers, his performance on the stage is extremely embellished by the beauty of his person, and grace and propriety of his gestures. We expected a great singer, but that does not always include a fine actor.

As Marchesi was the last of three great singers who appeared on our stage at the latter end of the eighteenth century, and as each had his exclusive admirers, it would be difficult to draw a studied parallel between them to the satisfaction of all parties; comparative praises, as well as censure, would be thought invidious. But as we have received great pleasure from the talents of each of these exquisite performers, and never expect to find abilities exactly similar in different singers, we are always thankful for the good we find, and endeavour to hear the rest with candour.

In discriminating the several excellencies of these great performers, we should without hesitation say, that Pacchierotti's voice was naturally sweet and touching; that he had a fine shake, an exquisite taste, great fancy, and a divine expression in pathetic songs. That Rubinelli's voice was full, majestic, and steady; and besides the accuracy of his intonations, that he was parsimonious and judicious in his graces. And that Marchesi's voice was elegant and flexible; that he was grand in recitative, and unbounded in fancy and embellishments.

All seem to have studied their art with great diligence during youth, and to read music as easily as their native language.

As actors: Pacchierotti seemed in earnest on the stage, and consequently interested the spectator. Rubinelli had great dignity in his deportment, though he discovered but little sensibility by his gestures or tone of voice. Marchesi, with an elegant figure and pleasing countenance, is at once graceful and intelligent in his demeanour and action.

Marchesi has continued to support his character of a great

and refined singer, ever since he quitted England fifteen years ago, and we believe still continues to exercise his talents on the stage.

When the French first invaded the Milanese, during the revolution, report says that he was treated by the military with savage indignity, for declining to obey a peremptory order to sing to the Gallic general's lady; to which he felt a repugnance from gratitude to the Austrian government, under which he had frequently resided, and been not only honourably but kindly treated. On his not instantly obeying the ungracious order that was sent him, he was seized by a party of soldiers, who, to deface his personal charms, deprived him of one eye-brow, and of half his fine head of hair.

MARCHESINA, in *Geography*, a town of Italy, in the department of the Montagna; 10 miles S.W. of Lecco.

MARCHESVAN, in *Chronology*, the eighth month of the Jewish ecclesiastical year, answering to part of our October and November.

MARCHET, or MARCHETTA, a pecuniary fine, anciently paid by the tenant to his lord, for the marriage of one of the tenant's daughters.

This custom obtained, with some difference, throughout all England and Wales, as also in Scotland; and it still continues to obtain in some places. According to the custom of the manor of Dinover in Carmarthenshire, every tenant, at the marriage of his daughter, pays ten shillings to the lord, which, in the British language, is called *gwahr-merched*, i. e. *maid's-fee*. See AMABYR.

In Scotland and the north parts of England, the custom was, for the lord to lie the first night with the bride of his tenant; but this usage was abrogated by king Malcolm III. at the instance of his queen; and, instead thereof, a mark was paid by the bridegroom to the lord: whence it is called *marcbeta mulieris*. See BOROUGH-English.

MARCHETTI, LA, in *Biography*, a singer from Bologna, engaged for the Pantheon in 1774. She had a powerful, brilliant, and sweet-toned voice, with which she might have become a singer of the first class; if want of health had not prevented her from that persevering practice, which is so necessary to the vanquishing of vocal difficulties. Besides singing at the Pantheon during her residence in England, she performed the second woman's part in Sacchini's operas of "Nitteti" and "Perseo."

MARCHETTI, PETER DE, a physician, was professor of anatomy at Padua, his native place, where he continued to teach that art from 1652 until 1669, when he was allowed to resign his chair to his son Anthony. In the year 1661, he also obtained the appointment to the first professorship of surgery, the duties of which he fulfilled at the same time with those of his anatomical chair. His merits in these departments of the profession obtained for him the honour of knighthood of the order of St. Mark. At the age of 80 years, he retired altogether from the university; and, after having enjoyed a short period of repose, he died in April 1673. He left the following works: "Anatomia," in 4to. Venice, 1654. "Sylloge Observationum Medico-chirurgicarum rariorum," Padua 1664, which was afterwards several times reprinted, and was translated into German. It contained fifty-three cases of some interest, and three tracts on ulcers, on fistulae of the urethra, and on ipina ventosa.

His two sons, DOMINIC and ANTHONY DE MARCHETTI, were likewise both professors in their native university of Padua. The former was author of a good compendium of anatomy, according to the judgment of Haller, which

passed through several editions, under the title of "Anatomia, cui Responiones ad Riolanum, Anatomicum Paritientem, in ipsius animadversionibus contra Vellingium, additæ sunt," Padua 1652, &c. Eloy Dict. Hist. de Med.

MARCHETTI, ALEXANDER, a poet and mathematician, was born at Pontormo, in the Florentine territory, in the year 1632. Being deprived at a very early period of his father, he was intended for a mercantile life; but it being soon discovered that he had decidedly a literary turn, he was placed with a professor of the civil law. This proved as little adapted to his taste as trade; and he was sent by the kindness of Leopold, cardinal de Medici, to the university at Pisa, where he pursued his favourite studies in belles lettres, in conjunction with philosophy and mathematics, in the latter of which he enjoyed the particular instructions of Borelli. He took a doctor's degree in 1659, and became professor of logic in that university, and also taught the elements of geometry to a private class under Borelli. In 1669 he published a mathematical work, entitled "Resistentia Solidorum;" and in a short time after, another with the more general title, "Exercitationes Mechanicæ." By the former he gained a high reputation; but the latter did not at all answer the expectations which he had raised by the other. About the same period he accomplished his translation of Lucretius, "De Rerum Natura," into Italian blank verse, which has contributed more to establish his fame than all his other pieces. It has been said that it surpasses almost every other classical version in modern language, in dignity, elegance, and clearness. Marchetti was desirous of dedicating this performance to Cosmo III., great duke of Tuscany; but the piety of that prince was so much shocked by the impious doctrines of the Epicurean philosophy, that he not only refused the dedication, but prohibited the publication of the work in his dominions; and it was not printed till after the author's death, by Paul Rolli, in the year 1717. It has since been frequently reprinted, and is allowed a place among standard works of the kind. He died in the year 1714, in his eighty-third year. In his youth he had translated the first five books of the Æneid, and likewise the odes of Anacreon. He had also composed several original poems, especially of the lyric kind, which were reckoned to possess great merit. These and other pieces had been printed in collections of Italian poetry. Marchetti had a very high opinion of his own talents as a mathematician and philosopher; but he was, at the same time, mild and easy, and ready to do good offices to any persons. He had been in habits of correspondence with many literary characters of distinguished eminence.

MARCHETTO DA PADOVA, an intelligent writer on music in the thirteenth century, of whose works we found two unedited MSS., preserved in the Vatican library, N^o 5322. The first is entitled "Lucidarium Artis Musicæ planæ," beginning, "Cum inquit," &c.; and the second, "Pomerium Artis Musicæ Mensurabilis: quatuor sunt Causæ," &c. The Lucidarium is frequently mentioned by Franchinus, Pietro Aaron, and other old musical writers of Italy.

There was a copy of this last-mentioned tract in the Ambrosian library at Milan, in 1770, D. 5, in folio, where it is laid to have been begun at Cesena, and finished at Verona, 1274: "Lucidarium in Arte Musicæ planæ, inchoatum Cesena, perfectumque Veronæ," 1274. The copy of his works in the Vatican was dedicated to Charles, king of Sicily, about the year 1283: "Marchettus Paduanus qui suum opus Karolo Regi Siciliæ dedicavit circa annum 1283."

We obtained large extracts from this MS., as it contained the most early mention that we had met with of the *diefis*, or accidental *sharp*, of *chromatic counterpoint*, *discords*, and the proportions of such concords and discords as are used by the moderns in practical harmony.

His examples of counterpoint, in the MS. whence our extracts were made, like those of Franco, are written upon only one staff of four, five, six, or more lines, according to the distance of the intervals, with two clefs, one for the base, and one for the tenor or upper part, with this peculiarity of notation, that the notes of the upper part are written in *red ink*, and the lower in *black*.

This MS. contains many curious attempts at infant harmony. Marchetto is the first who speaks of discords and their resolution; and lays it down as a rule, that no two sevenths, or fourths, used as discords, should succeed each other; and that after a discord, the part which has offended the ear should make it amend by becoming a concord, while the other stands still: indeed he never mentions the preparation of discords.

MARCHETTO CARA, an Italian singer, mentioned with Bidon, another contemporary vocal performer, with great eulogy, by Castiglione, in his "Cortegiano," written about the beginning of the sixteenth century. What kind of secular music the Italians cultivated, before the general use of counterpoint was established, we know not; but we find in the Lives of their first Painters, that many of them had been brought up to music, as a profession. Leonardo da Vinci was a great performer on several instruments, and invented a new species of lyre, in the shape of a horse's skull. (Da Teshio di Cavallo. Vafari, Vite di Pitt.) Italy had likewise, at this time, singers with great talents for execution and expression; for Castiglione, speaking of the variety and power of contrast in the arts, observes, that "instances of dissimilar things producing similar effects that are equally pleasing and meritorious may be given in them all; particularly music, in which the movement is sometimes grave and majestic, and sometimes gay and animated, yet equally delightful to the hearer. Thus, in singing, what can be more different than the performance of Bidon and Marchetto Cara? The one artificial, rapid, nervous, vehement, and impassioned, elevates and inflames the soul of every hearer; while the other, more gentle, pathetic, and insinuating, soothes, calms, and affects by a sorrowful and tender sweetness, which penetrates the heart, and affords it the most exquisite pleasure of a different kind." This description the late Mr. Galliard (Translation of Tosi, p. 170.) has thought applicable to the different powers of the two great female singers, Faustina and Cuzzoni, the superiority of whose abilities was so disputable when they performed on the same stage in England, 1727, that the patrons and friends of the one became inveterate enemies to those of the other.

Great natural powers will sometimes astonish and charm without much assistance from art; and so late as the year 1547, Pietro Aaron (Lucidario in Musica, fol. 31.) gives a list of such extraordinary performers as were able to *sing by book, cantori a libro*; by which we may suppose that the art was new and uncommon. And according to Tartini, (Trattato di Musica, p. 17.) "The old Italian songs being only made for a single voice, were simple in the highest degree; partaking of the nature of *recitative*, but *largo*:" (as the gondoliers at Venice still sing the *stanzas* of Tasso.) "None were confined to regular bars; and the key was determined by the kind and compass of voice that was to sing them."

However, during the sixteenth century, when the works

of Palestrina appeared, the Italians may with justice be said to have given instructions to the rest of Europe in counterpoint, as, ever since operas were established, they have done in singing.

MARCHI, FRANCIS, a famous military engineer, who flourished in the sixteenth century, was a native of Bologna. He is chiefly known by a book, entitled "Della Architettura Militaire," which was published in 1599, in folio. This, which contains 161 figures, is an extremely scarce book; a circumstance that has been attributed, by some Italian writers, to the suppression of most of its copies by certain French engineers, who passed off his inventions for their own. It was probably a work of vast labour, as it was begun in the year 1546, and was not completed till after the death of the author. It is said to contain the germ of several contrivances, which have since been adopted. The Italian writers maintain, that in it is to be found the origin of Vauban's method of fortification; but the French admit only a trifling resemblance between the two authors. *Gen. Biog.*

MARCHIENNES, in *Geography*, a town of France, in the department of the North, and chief place of a canton, in the district of Douay; 7 miles E.N.E. of Douay. The place contains 2309, and the canton 13,493 inhabitants, on a territory of 112½ kilometres, in 16 communes.

MARCHING, in *Military Language*. See MARCH and BATTALION.

MARCHING *Regiments*, a denomination given to those corps who had not any permanent quarters, but were liable to be sent not only from one extremity of Great Britain to another, but to the most distant of her possessions abroad. Although the term "marching" is insensibly confounded with those of "line" and "regulars," it was originally meant to convey the notion of something more than a mere liability to be ordered upon any service; for by marching the regular troops from one town to another, the inhabitants, who from time immemorial have been jealous of a standing army, lost their antipathy to *real* soldiers by the occasional absence of regular troops. At present, the guards, militia, and fencibles, may be considered more or less as marching regiments. The marines and volunteer corps have stationary quarters.

MARCHIONIS PULVIS, in the *Materia Medica*, a term used for a certain compound powder, prescribed in the Leyden Dispensatory, and greatly recommended by many as an anti-epileptic and absorbent.

The ingredients are, male piony-root, half an ounce, wood of mistletoe of the oak, raspings of ivory, elks' hoof, spodium, the tooth of the unicorn-fish, or, in its stead, the antlers of the stag's horn, red and white coral, and pearls, of each a dram. These are all to be rubbed into a powder, with twenty leaves of pure gold, and given half a dram twice a day.

MARCIAC, in *Geography*, a town of France, in the department of the Gers, and chief place of a canton, in the district of Mirande; 10 miles W. of Mirande. The place contains 1479, and the canton 8008 inhabitants, on a territory of 177½ kilometres, in 22 communes. N. lat. 43° 31'. E. long. 0° 14'.

MARCIANA, a town of Etruria; 30 miles E. of Florence.

MARCIANISI, a town of Naples, in Lavora; 10 miles N. of Naples.

MARCIANUS, in *Biography*, emperor of the East, was born of obscure parents about the year 391. His father served in the Roman army, into which he himself entered as a private soldier. Owing to sickness, he quitted

the station in 421; and upon the return of his health, he repaired to Constantinople, and enrolled himself among the troops commanded by Ardaburius, and his son Aspar. By his talents and good conduct he was raised to the post of secretary, in which quality he attended Aspar into Africa in 431. He was there taken prisoner by Genferic, who agreed, after a time, to liberate him upon a promise never more to serve against the Vandals. He soon attained the rank of tribune and senator; and on the death of Theodosius the younger, in 450, he was associated in the empire with Pulcheria. Attila was, at this time, threatening both empires. He had already sent an insolent message to the court of Constantinople, demanding the annual tribute which had been extorted from the weakness of Theodosius. The newly crowned emperor was not to be so treated: he boldly replied, "that he had gold for his friends, but had prepared steel for his enemies." This determined spirit was probably the reason that Attila turned his arms against the western empire, rather than the eastern. By the death of Pulcheria, he became sole possessor of the throne. He executed with the most pious fidelity her last wishes, by which she left a vast property to the church and the poor. After the death of Attila, several tribes of barbarians deserted the banners of his sons, and obtained permission from Marcianus to settle in Thrace and Illyrium; which countries had been almost depopulated by the incursions of the Huns. He died, much regretted, in the year 457, after a reign of about six years and a half. His piety and zeal in defence of orthodoxy were highly applauded by ecclesiastical writers: his rigorous edicts against heretics, and his kindness in recalling those who had been exiled on account of tenets which he espoused, gave him a high rank, and the title of saint in the Greek church; and he is entitled to general praise for his having bestowed his promotions only on persons of known abilities and unblemished character, whence the departments of the state were at all times filled with credit. *Univer. Hist. Gibbon.*

MARCIGLIANO, in *Geography*, a town of Naples, in Lavora; 9 miles N.E. of Naples.

MARCIGNY, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the district of Charolles; 12 miles S.W. of Charolles. The place contains 2414, and the canton 10,403 inhabitants, on a territory of 200 kilometres, in 12 communes. N. lat. 46° 17'. E. long. 4° 7'.

MARCILLOT, a town of France, in the department of the Allier, and chief place of a canton, in the district of Montluçon. The place contains 1414, and the canton 10,002 inhabitants, on a territory of 255 kilometres, in 16 communes.

MARCILLY LA HAYER, a town of France, in the department of the Aube, and chief place of a canton, in the district of Nogent-sur-Seine. The place contains 488, and the canton 6049 inhabitants, on a territory of 400 kilometres, in 24 communes.

MARCIONITES, or MARCIONISTS, *Marcionists*, in *Ecclesiastical History*, a very ancient popular sect of heretics, who, in the time of St. Epiphanius, were spread over Italy, Egypt, Palestine, Syria, Arabia, Persia, and other countries: they were thus denominated from their author Marcion.

Marcion was of Pontus, the son of a bishop, and at first made profession of the monastic life; but he was excommunicated by his own father, who would never admit him again into the communion of the church, not even on his repentance. The cause of his father's displeasure is said by Epiphanius to have been a criminal connection with a young woman;

MARCIONITES.

woman; but Beaufobre and Lardner have alleged a variety of reasons that render this story incredible, and that lead them to suppose that it was a fabrication of Epiphanius. Beaufobre supposes that the crime of this heresiarch, for which his father expelled him from the church, was his errors, which he had begun to publish in his own country. On this excommunication, he abandoned his native land, and retired to Rome, where he became acquainted with Cerdon, and, as some have said, became his disciple; and adopting his opinions, zealously propagated them.

Cave supposes that he came to Rome in the year 127; and that about the year 130 he became a follower of Cerdon, and an open heretic. According to Pagi, Marcion came to Rome after the death of Hyginus, which, he thinks, cannot be deferred beyond the year 141. But he had before broached his opinions in Syria, probably in the reign of Adrian, or at least in the beginning of the reign of Antoninus the Pious. When he came to Rome, the see was vacant by the death of Hyginus; but as the presbyters did not receive him, he returned to Asia, and spread his tenets with less disguise and greater zeal, about the year 144, where Tertullian and also Petavius place him. As Justin Martyr wrote against Marcion, and his "Apology" was written in the time of the elder Antoninus, in the year 140, or not long after, it is reasonable to think, says Dr. Lardner, that Marcion had appeared in the year 130, or very soon after; for Marcion had many followers when Justin wrote that Apology: and when he says that Marcion was still living, it is implied that he had made a figure for some time.
